The results are presented in Fig. 1 as a plot of per cent lysis versus relative antibody concentration. Antibody concentrations were examined in each system which gave approximately the same amount of lysis in the absence of ethylenediamine tetraacetic acid. This was done so that with ethylenediamine tetraacetic acid added, the relative amounts of antibody required for lysis in each system could be directly compared. It can be seen that, although the relative amounts of antibody in each system gave equivalent lysis in the absence of ethylenediamine tetraacetic acid, the relative amounts of antibody required for lysis in the presence of ethylenediamine tetraacetic acid were strikingly different for each system. Twice the concentration of antibody was required in the rabbit anti-human system for sufficient $EAC'_{1,4,2}$ complex formation at 0° C. to obtain lysis equivalent to that which was obtained in the absence of ethylenediamine tetraacetic acid. The rabbit anti-sheep and human anti-A serums with sheep cells required approximately 60 and 95 times respectively the amount of antibody to obtain equivalent lysis in the presence of ethylenediamine tetraacetic acid. These findings correspond well with the ratios of the hæmolysin and C'-fixing titres previously obtained for these systems[1].

These results illustrate differences in the ability of these hæmolytic systems to form the $EAC'_{1,4,2}$ complex at 0° C., as judged by the relative amounts of antibody required for lysis with the addition of ethylenediamine tetraacetic acid. These results further show that the hæmolysin titres in the presence of ethylenediamine tetraacetic acid are unrelated to the hæmolysin titre in the absence of ethylenediamine tetraacetic acid. However, the hæmolysin titres in the presence of ethylenediamine tetraacetic acid do show a relationship to the C'-fixing activities of these systems.

Effect of Cross-linking by Formaldehyde on the Contraction–Relaxation of Rat Tail Tendon

RECENTLY, Banga *et al.*[1] demonstrated that tendons of the tail of a rat spontaneously shortened and relaxed when they were placed in 40 per cent potassium iodide at room temperature. Aging influenced the length–time curves so that rapid contraction was followed by rapid relaxation in the young but slow relaxation in the old. Cross-linking in collagen has been a widely discussed concept of the effect of the aging process. If the development of more highly polymerized collagen is the effect of aging then tanning young tendons with formaldehyde, a cross-linking reaction, should 'age' them a certain amount. The following experiments were done to test this hypothesis.

Tendons of the tail of a rat, having mass/length ratios of 0·3–0·4 mgm./cm., were treated for 15 min. by exposing them to various dilutions of 37 per cent formalin in sodium acetate solutions buffered at *p*H 7·8. Following treatment, 6-cm. lengths were clamped inside a glass cylinder where the bottom end of the fibre was fixed and the top was free to actuate the direct writing arm of an electrically driven kymograph. A mechanical magnification of × 5 was obtained for the curvilinear co-ordinate system. Plots were made in rectilinear co-ordinates of length as a function of time for each tendon studied. The net force on the tendon was estimated at between 1 and 2 gm. but was constant throughout the study. Chemical contraction was induced at 23° C. by using freshly prepared aqueous 40 per cent potassium iodide, which was added rapidly to the tube containing the fibre.

Fig. 1 shows that the length–time curves depend upon the concentration of formaldehyde used for cross-linking collagen in the tendons. At 1/1,000 dilution, the fibres contracted 65 per cent of their length in less than 10 min. and remained so for at least 50 min. At 1/100,000 dilution there was a 40 per cent decrease in length in less than 5 min. which returned to the original length 40 min. later. These measurements were repeated using 0·5 *M* acetic acid instead of 40 per cent potassium iodide, and the same response was obtained to formaldehyde treatment.

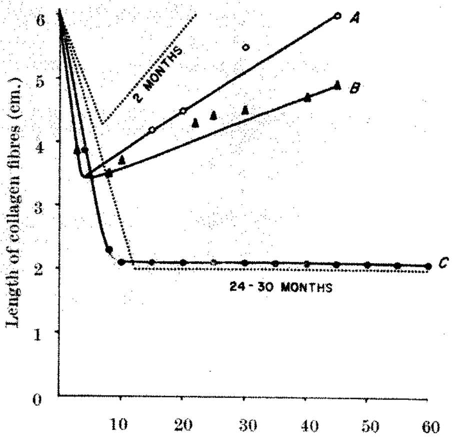

Fig. 1. The contraction–relaxation of tendons of the rat tail induced by 40 per cent potassium iodide as a function of degree of cross-linking by formaldehyde. *A*, 1 : 10,0000 formalin; *B*, 1 : 10,000 formalin; *C*, 1 : 1,000 formalin; - - - -, untreated collagen fibres; ——, formalin-treated fibres

The reaction of aldehydes on collagen has been studied many times. It is generally accepted that at alkaline *p*H the terminal amino-group of lysine in the collagen reacts with formaldehyde to form a part of the cross-link[2]. Solomons and Irving[3] have shown that there is a direct relationship between the degree of mineralization in bone and the amount of bound lysine and hydroxylysine. The solubilization of hide collagen by concentrated acetic acid solutions also involved the lysine residue as shown by Elden *et al.*[4] from spectroscopic studies of collagen–acetic acid–formaldehyde interactions. In view of the similarity between the effect of aging and formaldehyde cross-linking on the length–time curves of tendon we suggest that collagen lysine and hydroxylysine might be involved in the changes taking place.

Wiederhorn *et al.*[5] cross-linked kangaroo tail tendon with formaldehyde and measured its elasticity after thermal shrinkage. The stress required for a fixed elongation was greater after the treatment. According to Flory[6], the force required to produce a fixed amount of strain must be higher with more cross-linking. At a fixed amount of force the elongation would be less. In the tendon of the kangaroo there was an increase in cross-linking with a reduction in the molecular weight between bridge points from 55,000 to 15,000.

The thermal shrinkage of collagen has features which suggest that it is a true phase-transition[7]. Solubilization by dilute acetic acid resembles the first step in a recently proposed two-step mechanism for the thermal conversion of the crystalline region of collagen to an amorphous phase. Contraction of tendons in 0·5 *M* acetic acid and 40 per cent potassium iodide is the mechanical consequence of such transitions. The thermally induced phase transition does not produce viscous-flow characteristics. Therefore, relaxation cannot proceed because of irreversible slipping of melted crystallites.

To sum up the above comments we have the following facts: (1) aging increases the extent of contraction but decreases relaxation of rat tail tendons. (2) Introducing cross-links by formaldehyde treatment affects the length–time curves in a manner comparable to the aging process. (3) The action of 40 per cent potassium iodide and acetic acid (0·05 *M*) are such as to induce a phase change with concomitant shortening of the tendons. Relaxation diminishes with aging. Under a fixed load the length of 'elastic' collagen decreases (contraction increases) when further cross-links are introduced. (4) Relaxation is due to the partial dissolution of the tendon by the solvent allowing the chains of collagen to unfold.

These facts are consistent with the concept that an increase in cross-linking of collagen occurs with aging.

Electrical Conductance and Dielectric Constant of the Interior of Erythrocytes

THE electrical conductivity of an electrolyte is determined by its ion concentration. The effect of dispersed solid particles of a comparatively low conductance, such as proteins, can be taken into account using formulæ given by Maxwell[1] and Fricke[2]. Hence, an analysis of the electrical conductivity of the cell interior should provide information about the organization of its protoplasm.

In 1912, Höber[3] reported specific resistance values of the interior of beef erythrocytes between 160 and 600 ohm cm. Fricke and Morse[4] gave for beef and sheep erythrocytes 310 ohm cm. and Fricke and Curtis[5] later on for sheep, rabbit, chicken and turtle 140 ohm cm. Rajewsky and Schwan[6] and Cook[7] quote values of 100–110 ohm cm. for human erythrocytes. Measurements of Li and Schwan[8] indicate values near 200 ohm cm. for beef erythrocytes. In order to clarify whether these discrepancies reflect true species differences or differences in methods, additional investigations with erythrocytes of several species were undertaken[9]. Fresh heparinized blood was tightly packed by centrifugation. The erythrocyte sediment contained 2–5 per cent trapped plasma as judged from the consistency of calculated internal data with different packing factors and from the established performance of the hæmatocrit centrifuge[10].

Conductivity $\varkappa$ and dielectric constant relative to free space ε were measured with an admittance bridge (*RX*-Meter 250-*A*) from 0·5 to 250 Mc.

The reactance of the cell membrane vanishes[11] at about 70 Mc. Hence, $\varkappa$ and ε of completely packed erythrocytes are identical with internal values of the erythrocytes above 70 Mc./s. This was checked by investigation of the low-frequency conductance of erythrocyte suspensions after destruction of the insulating membrane with either saponin or toluene. Measured values were corrected for the small amount of trapped plasma in order to obtain values characteristic of the interior. This was done by use of equations given by Fricke[2]. While the exact validity of these formulæ may be questionable, no significant error should result from this procedure.

Results are summarized in Table 1 for seven different species. The internal resistance between the different animals varies by not more than 15 per cent. Differences are significant within 3 per cent. However, the dielectric constants of the several species, accurate to 1 dielectric unit, are not significantly different. The average of all dielectric constants values is 52 and close to previously published values[6]. It is due to the hæmoglobin content of the cells corresponding to a dielectric decrement of about 0·7 unit per gm. hæmoglobin per 100 c.c.[11]. The internal conductivity cannot be readily explained by the known electrolyte content, even if an activity coefficient of a 0·2 *M* potassium chloride solution is assumed and the non-conducting volume of the hydrated hæmoglobin is considered. The calculated conductivity values are higher than the internal results reported above by a factor of 2. Partial binding of ions to protein and reduction of their mobility may provide explanation for this fact. Similar discrepancies are indicated in the case of liver cells[9,12], frog muscle[13], and nerve fibres[14]. This suggests that the lower conductance is a general property of cell plasm.

Table 1. INTERNAL SPECIFIC RESISTANCE ρ, CONDUCTIVITY $\varkappa$ AND DIELECTRIC CONSTANT ε OF RED BLOOD CELLS (Temperature, 25° C.)

Synthetic Activity of Polynucleotide Phosphorylase from Sperm

POLYNUCLEOTIDE phosphorylases are enzymes that catalyse the synthesis of polyribonucleotides.

No evidence has yet been given for the presence of polynucleotide phosphorylase in extracts of animal tissues, although these enzymes have been found in extracts of aerobic or anaerobic Gram-positive or Gram-negative bacterial cells[1–4].

A polynucleotide phosphorylase was isolated and partially purified from the human sperm. The enzyme was prepared from vacuum-dried human sperm by the method of Littauer and Kornberg[5]. The preparation obtained was further purified by ammonium sulphate fractionation, and by zinc ethanol precipitation. The precipitate obtained, between 15 and 20 per cent, was adsorbed on an equal volume of calcium phosphate gel. The pure enzyme was then eluted from the gel and activity determined.

The enzymic reactions were carried out in solutions where each 5·0 ml. portion contained *M*/10 trihydroxymethyl-amino-ethane buffer, *p*H 8·0, *M*/60 magnesium chloride, *M*/15 of either adenosine-5′-diphosphate, guanosine-5′-diphosphate, uridine-5′-diphosphate or cytidine-5′-diphosphate, each alone or in pairs, and 0·5 ml. of 5 per cent solution of the sperm enzyme.

Chromatograms of the reaction solutions were developed by the descending technique in two dimensions. The solvent systems used were ammonium–*iso*butyric acid and tertiary amyl alcohol–formic acid–water[6,7]. Permanent records of the chromatograms were obtained by the photographic technique[7]. The polynucleotides located were cut out from the chromatograms and eluted. The ultra-violet absorption spectrum, chemical identity and concentration were studied.

Influence of Vitamin D on Synthesis of Hexosamine by Rachitic Rat Cartilage

IT is believed that chondroitin sulphate or its protein complex plays a very important part in the process of calcification[1]. The fact that during calcification there is a marked increase in metachromatic staining in the region which exhibits calcification led Rubin and Howard[2] to postulate that either there is an increase in the concentration of the mucopolysaccharide or that there is a change in its state of polymerization. In the former case it is possible that the enzyme system responsible for synthesizing chondroitin sulphate or some of its components would show an increase during the healing of rickets brought about by vitamin D, just in the same manner as the citric acid content and the enzyme concerned with its formation were found to show an increase in the rachitic epiphyseal cartilage of rat and dog after vitamin D administration[3]. Castellani and Zambotti[4] have recently demonstrated that the epiphyseal cartilage of growing rabbit contained appreciable amounts of a thermolabile enzyme system which synthesizes one of the components of chondroitin sulphate, namely, hexosamine from glutamine and glucose-6-phosphate. In view of these considerations, it was felt desirable to investigate whether vitamin D influenced the enzymatic synthesis of hexosamine in the rachitic cartilage.

For this study young albino rats, four weeks old, were fed a rachitogenic diet[5] for two weeks. At the end of this period the rachitic animals were divided into two groups, taking litter and sex distribution into account. Animals in group 1 served as rachitic controls; those in the other were each administered a single dose of vitamin D (4,000 I.U.) 96 hr. earlier. The animals from both groups were killed on the same day, and cartilage from the distal end of femur and the proximal end of tibia was removed from the four rats in each group. The pieces of cartilage were pooled, weighed and ground in a chilled mortar with a known volume of a cold solution of 10^{-2} *M* glutamine and 10^{-2} *M* glucose-6-phosphate in 0·1 *M* citrate buffer (*p*H 6·4), and hexosamine formed enzymatically was determined as described by Castellani and Zambotti employing Schloss's method[6]. As shown in Table 1 there is an appreciable rise in the hexosamine-synthesizing capacity of the rachitic rat cartilage as a result of vitamin D administration.

Table 1. EFFECT OF VITAMIN D ON THE ENZYMATIC FORMATION OF HEXOSAMINE BY RACHITIC RAT EPIPHYSEAL CARTILAGE

No. of observations	μgm. Glucosamine/gm. wet tissue in 3 hr.				
	Rachitic *A*	96 hr. after vitamin D *B*	*B* — *A* *S.E.*	*t*	*P*
5	267 (19)	459 (20)	192 ± 38·5	4·97	< 0·01

Number of rats employed is indicated in parentheses.

It was therefore logical to expect that on administration of vitamin D to rachitic animals the concentration of chondroitin sulphate or its hexosamine component in the cartilage would show an increase. This point was therefore investigated. Young rats were made rachitic as described above and distributed equally into four groups. Animals in group 1, which served as rachitic controls, were killed and their tibial epiphyseal cartilage quickly removed, placed individually in tubes and dried at 75° C. for 4 hr. Animals in the other groups were administered a single dose of vitamin D (4,000 I.U.), killed 48, 96 and 144 hr. later and the tibial cartilage was scooped out and dried. The dried cartilage was weighed and hydrolysed with 3·0 ml. 4 *N* hydrochloric acid at 100° C. for 12 hr. The hydrolysate was made to volume in a 10 ml. volumetric flask and aliquots taken for hexosamine determination. As shown in Table 2, there is a small, but significant, fall in the hexosamine content of rachitic rat cartilage during healing induced by vitamin D.

Table 2. EFFECT OF VITAMIN D ON HEXOSAMINE IN μGM./MGM. DRY RACHITIC RAT CARTILAGE

Rachitic controls	Hours after vitamin D treatment		
	48	96	144
Group 1	2	3	4
S.E. 117·8 ± 5·55	*S.E.* 97·5 ± 4·00	*S.E.* 89·3 ± 6·25	*S.E.* 87·3 ± 3·74
	Between groups 1 and 2	Between groups 1 and 3	Between groups 1 and 4
t	2·97	3·41	4·56
P	< 0·02	< 0·01	< 0·001

It was indeed surprising that although vitamin D enhanced the capacity of the healing cartilage to synthesize hexosamine enzymatically, there was no commensurate increase in the hexosamine content of cartilage, which in fact showed a slight decrease. It is difficult to reconcile these two contradictory observations. Further work might throw light on this interesting problem.

Incorporation of Labelled Thymidine in the Seminal Vesicle of the Mouse

IT has been reported that labelled adenine is incorporated into the deoxyribonucleic acid of the seminal vesicle of the mouse at a rate far exceeding that required for cell-division in the organ[1]. In view of the implications of this finding it seemed desirable to repeat the experiment with ^{3}H-thymidine, which can be regarded as a specific precursor for deoxyribonucleic acid[2]. The present communication deals with the incorporation in the seminal vesicle and, for comparison with a dividing tissue, in the œsophagus of the same animals.

Eleven mice of an inbred strain were injected intraperitoneally with 16·7 μc. each of ^{3}H-thymidine with a specific activity of 360 mc. per m*M*, supplied by Messrs. Schwarz Inc., Mount Vernon, N.Y. Animals were killed 1–7 days later, organs were fixed for 1 hr. in acetic acid–alcohol followed by 24 hr. in formol saline, embedded in paraffin wax and sectioned at 5–6μ thickness. Autoradiographs of unstained or Feulgen-stained sections were prepared by the stripping-film technique and exposed for 13 or 23 days. Unstained specimens were stained with Ehrlich's hæmatoxylin and eosin after photographic processing. The background of the autoradiographs is 0·3–0·5 grains per nucleus.

A number of nuclei of epithelial cells of the seminal vesicle are labelled 24 hr. after injection. The intensity of labelling after 13-days exposure averages 15 grains per positive nucleus in the seminal vesicle, compared with 13 grains per positive nucleus in the basal layer of the œsophagus. The most heavily labelled nuclei show up to 50 grains in both tissues.

Table 1. COMPARISON OF LABELLING OF DEOXYRIBONUCLEIC ACID AND CELL DIVISION IN THE SEMINAL VESICLE AND ŒSOPHAGUS OF MICE

	SI (per cent)	*MI* (per cent)	$\frac{SI}{MI}$
Seminal vesicle	4·4 ± 0·9	0·05 ± 0·02	88
Œsophagus	18 ± 1·1	9·5 ± 1·0	1·9

SI, No. of labelled nuclei per 100 cells 24 hr. after injection of labelled thymidine.

MI, No. of metaphases per 100 cells after 6 hr. treatment with colchicine.

$\frac{SI}{MI}$, the ratio of labelled cells to dividing cells as scored under the experimental conditions in this investigation.

No corrections for absorption of β-particles or loss of material through sectioning of nuclei of different size have been made. Furthermore, it is by no means certain that the supply and dilution by the pool of unlabelled thymidine of the injected ^{3}H-thymidine are the same for œsophagus and seminal vesicle. It can, however, be concluded that those nuclei which incorporate labelled thymidine do so at approximately the same rate in both tissues, though differences may be masked by the sources of error mentioned.

The seminal vesicle of mice killed 24 hr. after injection contains 4·4 ± 0·9 per cent (Table 1) labelled nuclei while the basal layer of the œsophagus shows 18 per cent. Analysis of the movement of labelled nuclei in the Malpighian layer of the œsophagus indicates that the differentiating cells are replaced every 2–3 days[3], so that the relatively low figure of 18 per cent labelled nuclei indicates that labelled thymidine is used up 8–12 hr. after injection, in agreement with data recently published by Hughes *et al.*[4]

The number of nuclei incorporating ^{3}H-thymidine is thus four times higher in the basal layer of the œsophagus than in the seminal vesicle ; the ratio of cell division should be similar in the two tissues if all incorporation were in preparation for mitosis. Allen[5], however, has found only 40 mitoses per 100,000 cells after 6 hr. treatment with colchicine, equivalent to 160 divisions per 100,000 cells per day or an average life-span of approximately 600 days. Mitotic counts on sections adjacent to those used for autoradiography and on Feulgen-stained sections of mice killed 6 hr. after injection with colchicine agreed with Allen's data (Table 1). No signs of cell degeneration such as pycnosis or extrusion of cells into the secretion were observed. Measurements of the amount of deoxyribonucleic acid per nucleus by means of Feulgen-photometry (Richards, B. M., private communication) in polymorphs and nuclei of the seminal vesicle gave a narrow range of diploid values. No intermediate or polyploid values were found.

Incorporation of ^{3}H-thymidine into the deoxyribonucleic acid in the seminal vesicle of the mouse is therefore approximately forty times higher than could be expected from the known rates of proliferation in this organ. This excess is far beyond the limits of error of the techniques employed.

Depending on the length of time during which thymidine is available, the rate of incorporation in 4·4 per cent of the nuclei of the seminal vesicle is equivalent to a renewal of 4·4–13 per cent of its deoxyribonucleic acid per day. From the rate of incorporation of labelled adenine a renewal of 10 per cent per day was calculated[1]; the two methods therefore agree as well as can be expected.

The proportion of labelled nuclei is well maintained up to seven days after injection. Cell counts and grain counts undertaken so far suggest a decline between the third and seventh day, which, however, may not be significant in view of the small number of animals used in this investigation.

Since most of the incorporation of ^{3}H-thymidine in the epithelial cells of the seminal vesicle does not lead to mitosis a metabolic function of this process has to be assumed. Metabolic activity of deoxyribonucleic acid was originally discovered by means of the incorporation of labelled phosphate in rat liver by Ahlstrom, v. Euler and Hevesy[6]. The results of later experiments which give similar results have been reviewed in a previous communication[1]. They lead to the conclusion that deoxyribonucleic acid is metabolically almost completely stable in adult brain, cartilage and muscle, that it is renewed at a rate approaching 1 per cent per day in normal rat liver and pancreas, and proceeds at a rate similar to that found in dividing tissues in Jensen rat sarcoma, transplantable mouse mammary carcinoma, lung, intestinal mucosa, mouse prostrates grown in organ culture and in the seminal vesicle of the mouse.

It is of interest to note that our findings, similar to recent observations on incorporation of labelled thymidine in bean roots[7], suggest that all, or at least most, of the deoxyribonucleic acid contained in nuclei is taking part in metabolic activity which therefore is unlikely to be connected with genetic specificity of deoxyribonucleic acid.

We wish to thank Dr. H. B. Fell for much helpful discussion and Prof. J. T. Randall for his interest and for providing facilities.

Terminology of Hormones

A NEED has been felt for a precise terminology to distinguish four types of animal hormones by their actions[1,2]. (1) 'Metabolic' hormones stimulate or inhibit clearly defined metabolic processes. This term is in general use for such hormones as thyroxine and a secretion from the insect corpus allatum, both of which increase oxygen consumption, or for the hydrocortisone-like hormones from the adrenal cortex and a neuro-secretion from the insect brain, both of which increase diuresis. (2) 'Morphogenetic' hormones promote growth and cell differentiation. This term can be used for thyroxine when it has a morphogenetic action in stimulating amphibian metamorphosis. The hormone, ecdysone, from the prothoracic gland of some insects is also morphogenetic, since it promotes moulting and ecdysis. There is obviously some overlap between the hormones in these two groups, since no growth can occur without the support of many metabolic processes ; but metabolic actions can occur without growth and can usually be examined and described independently. The distinction in terms can help to clarify this.

(3) These hormones control the relatively rapid and repeatable actions of effector organs. They form a very distinct group, for which we propose the term 'kinetic', since no other name has been generally accepted. They include oxytocin and other hormones acting on muscles, chromactivating substances from the ganglionic X-organ–sinus gland complex of crustaceans acting on retinal cells and chromatophores and secretin among those controlling exocrine glands. They have been referred to as energetic[3]; but this is not a term that distinguishes them clearly from metabolic hormones. Great confusion surrounds the use of the suffixes trophic or tropic not only for some of these kinetic hormones, as in chromatophorotropic, but also for some of the morphogenetic hormones.

(4) Those kinetic hormones which stimulate the secretion of another hormone from an endocrine gland can be usefully distinguished by the rational, if not euphonious, term 'endocrinokinetic'. This includes hormones from the vertebrate adenohypophysis, such as thyrotrophin and adrenocorticotrophin, and also the interstitial-cell-stimulating hormone and luteotrophin. On the other hand, the follicle-stimulating hormone, which stimulates the growth and maturation of gonads, is mainly morphogenetic and so is the luteinizing hormone, since it promotes growth of the corpus luteum but does not stimulate it to secrete. The use of 'gonadotrophic' for all these four does not distinguish between their actions. The best known example of an endocrinokinetic hormone from an invertebrate is that which comes from the insect brain and stimulates the secretion of ecdysone.

Changes in the Osteoblastic and Mitochondrial Population of Aging Periosteum

EARLY investigators[1-4] interested in the physiology of bone have described filamentous, rod- and granular-shaped mitochondria in osteoblasts from a variety of animals both *in vivo* and *in vitro*. An apparent relation between the number of mitochondria and osteoblastic activity was also pointed out. Pritchard[5] arrived at the same conclusion. Within the past decade numerous biochemists have revealed a good many of the substrates and enzymes involved with intermediary metabolism associated with mitochondria. More recently, cytochrome oxidase and succinic dehydrogenase activity of the periosteum was studied in normal and traumatized rat femora from birth to old age[6,7]. The results showed high levels of activity of respiration becoming more elevated at the period of maximum rate of bone formation. Following this period of intense activity (5 weeks of age), a sharp drop occurred to a low level, which was maintained throughout the life of the animal. Trauma to the femora stimulated a response of respiratory activity, however, the response becoming progressively less with increasing age. Changes in respiratory enzyme-levels are fundamental to the activity of cells in general, because these enzymes are part of the aerobic hydrogen transport system from which rich-energy-bond phosphate is generated.

Since cytochrome oxidase and succinic dehydrogenase have been shown to be associated with mitochrondria[8], it was concluded that perhaps the changes in enzyme, noted with increasing age, reflected mitochondrial variations which resulted in changes in osteoblastic population. These alterations will be expected to effect the physiological functions of the periosteum in the processes of growth of bone and healing of fractures.

The experiments were performed to study the following: (1) quantitative changes in the osteoblastic population and their mitochondrial complement during the process of aging; (2) to relate these results to the previous respiratory enzyme findings; (3) to furnish a base-line for future studies of cytological changes associated with healing of fractures from birth to old age.

Long–Evans strain rats were used in the experiments and were divided into six age-groups containing ten animals each. Group I consisted of 1 week-old rats, Group II, 5 weeks-old, Group III, 8 weeks-old; Group IV, 26 weeks-old; and Groups V and VI, 52 weeks- and 104 weeks-old animals, respectively. Each group was subdivided into males and females. Intact femoral periosteum was obtained by shaving the mid-shaft of each bone. This method ensured the histological and cytological integrity necessary for proper measurements and eliminated the need of decalcification. Frozen sections were made and stained with janus green *B*. Additional tissues were fixed immediately with Regaud's fixative. Paraffin sections were prepared and stained with Regaud's iron hæmatoxylin.

Periosteal osteoblasts and their mitochondrial complement in contact with the preosseous zone were counted at each age. Special precautions were taken to count only the mitochondria of intact, non-distorted, free osteoblasts. The numerical data were evaluated for significance by statistical methods using Fisher's *t*, having a critical ratio of 2·797 and a probability of $P < 0\cdot01$.

Counts made of the number of periosteal osteoblasts adjacent to the preosseous zone revealed a slight

Table 1. A COMPARISON BETWEEN THE AVERAGE NUMBER OF OSTEOBLASTS PER UNIT AREA AND THE AVERAGE NUMBER OF MITOCHONDRIA PER OSTEOBLAST AT THE FEMORAL PERIOSTEUM OF RATS OF VARIOUS AGES

Age (weeks)	1	5	8	26	52	104
Average number of osteoblasts per unit area ± S.E.	10·2 ± 0·5	10·6 ± 0·4	10·5 ± 0·2	2·8 ± 1·9	3·5 ± 0·5	1·1 ± 0·2
Average number of mitochondria per osteoblast ± S.E.	28·4 ± 1·3	37·1 ± 2·4	16·8 ± 0·9	17·9 ± 1·4	9·5 ± 0·6	3·3 ± 0·5

S.E., standard error of the mean.

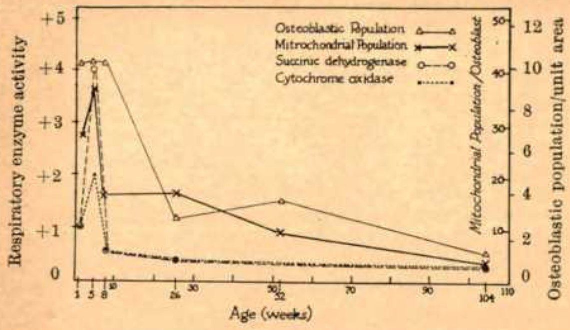

Fig. 1. A composite graph showing the relation between the shape of several curves at various ages. Note that the respiratory enzyme curves (succinic dehydrogenase and cytochrome oxidase) are similar to the mitochondrial population curve, and that the fall in respiratory enzyme activity and mitochondrial numbers precedes the disappearance of the osteoblasts from the periosteum

increase from birth to 5 weeks of age. This number was maintained to about 8 weeks of age, after which time there was a very significant fall in the number of osteoblasts in this region to 26 weeks of age. The following groups revealed a continued but less-severe diminution in the number of osteoblasts (Table 1). The mitochondrial complement of these cells also varied coincidentally with the variations noted in the number of osteoblasts. Mitochondria increased in number from birth to 5 weeks of age; however, only half this number was found by 8 weeks of age. The following ages revealed a progressive reduction in the mitochondrial complement (Table 1). A comparison of the number of osteoblasts, mitochondria and previously reported respiratory enzyme activity of the osteoblasts is given in Fig. 1. Morphological variations in osteoblasts were seen to occur following the numerical changes described (Fig. 2).

The results showed that a quantitative relation between the number of mitochondria and osteoblastic activity does exist, as has been pointed out by earlier investigators. It has also been shown that these changes precede the loss in the number of osteoblasts at the preosseous zone. Additional support is given by a comparison with respiratory enzyme findings[6,7], which were seen to parallel the mitochondrial changes. It is interesting to note that the reported drop in respiratory enzymes occurred also before the fall in the number of osteoblasts and that the greatest enzyme activities, number of mitochondria, and osteoblasts occur coincidentally with the period of maximum rate of bone formation in the rat. It appears, therefore, that during the processes of periosteal aging, biochemical changes are occurring associated with the mitochondrial complement of osteoblasts which are intimately involved with the long-recognized variations in the rate of bone growth and the observed morphological changes seen in ageing periosteal osteoblasts.

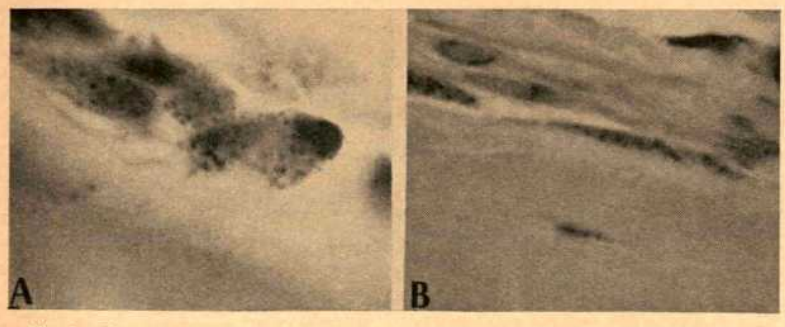

Fig. 2. Photomicrographs demonstrating the morphology of the periosteal osteoblasts and their mitochondrial complement in: (A) a 5 week-old rat and (B) a 1 year-old rat. Stained by Regaud's iron hæmatoxylin method. (× c. 700)

BIOLOGY

Differential Response of Male and Female Adults of *Trogoderma granarium* Everts towards Sterilizing Doses of Gamma-radiation

DURING a recent investigation into the tolerance of adults of *Trogoderma granarium* Everts to sterilizing doses of γ-radiation, it was decided to separate the sexes before treatment.

Previous work by Cornwell *et al.*[1] had shown that most insect pests of stored products could be sterilized by a dose of 6×10^3 rep. (In the present work, the rad has been used as the unit for measuring radiation. This unit has been adopted internationally for use in biological work in preference to the roentgen (r.), and the rep, both of which have been used in other works cited. The numerical differences between the three units are sufficiently small to enable reasonably accurate comparisons to be made between the results of others and the present work.

The work described here is a result of several trials with the adults of *T. granarium* which have shown that a dose of 5×10^3 rads (administered from a cobalt-60 source at 570 r. per min.) is sufficient to sterilize only the females of the species. The males (Table 1) are able to retain some fertility at dosages up to 15×10^3 rads, which is three times that required to sterilize the females.

It is interesting to compare this result with those of Bushland and Hopkins[2], who investigated the resistance of screw-worm flies, *Callitroga hominivorax* (Coq.), towards sterilizing doses of γ-radiation. In that case (where the insects were irradiated as pupæ) the sexes were also treated separately. In direct contrast to the present work, however, it was discovered that the males required less γ-radiation than the females to render them sterile. The males, in fact, were almost completely sterilized by a dose of $2 \cdot 5 \times 10^3$ r. given on the seventh (penultimate) day of the pupal stage. On the other hand, females laid eggs (which yielded a 50 per cent hatch) after being given a dose of 4×10^3 r. on the seventh day after pupation.

Table 1. NUMBER OF LARVÆ PRESENT AT EACH OBSERVATION. AFTER TREATMENT, EXCEPT AT THE HIGHEST DOSAGE, SEVEN MALES WERE CONFINED WITH TWICE THEIR NUMBER OF NORMAL NEWLY EMERGED FEMALES

Days after exposure of males	No. of larvæ present following γ-irradiation of males (dose in rads)			
	0	5,000	10,000	15,000*
3				
4				
5	5			
6	10	2	1	
7	30	4	3	
8		6	7	
9				
10		20		3
11		20	14	5
12			14	8
13		26	14	
14			16	
15				
16			16	
17			20	
18				
19			20	
20				
21	40	26	20	8

* Thirty males were irradiated and confined with thirty females.

Table 2. NUMBER OF MALES FOUND DEAD AT EACH OBSERVATION

Days after exposure	No. of males dead after dose (rads)			
	0	5,000	10,000	15,000
4	4	1		
5	2	1		4
6	0	1	1	5
7	1	3	4	5
8		1	2	12
9				3
10		26		1

The adults of *T. granarium* were irradiated immediately on emergence from the pupæ. Thus the difference between the resistance in the two sexes, when compared with *C. hominivorax*, cannot be attributed to irradiation of the insects at widely different stages in the development of the two species.

Some of the results (Table 2) indicate a possible increase in life-span following irradiation, and it is hoped to investigate the significance of such results in future work.

Measuring Productivity in Breeding of Small Animals

IT is nearly always desirable, when breeding animals like mice for laboratory use, to select for high productivity, that is, for the largest number of healthy offspring per dam in a given time. This is a function of litter size and 'pre-natal interval'; the time between exposure to the chance of mating and the birth of the first litter, or the time between the births of successive litters. The pre-natal interval is only of interest for monogamous pairs which are never separated.

Carter[1] suggested that the measure of productivity be the number of mice born and weaned, divided by the number of prenatal days. This index will be less than 1·0, occasionally less than 0·1, and to be useful it will contain two significant figures. Later it was suggested[2] that the reciprocal of Carter's index be used which will be a figure greater than 1·0 and occasionally greater than 10·0—also needing to have two significant figures. Carter's index is inconvenient owing to the decimal point; but it varies indirectly with the productivity. The other figure is more convenient but still contains a decimal point; however, it varies inversely with the productivity, which is an added inconvenience.

Thanks to a suggestion made by D. S. Falconer (personal communication), we now propose to use Carter's index multiplied by 100 as a measure of productivity, and to call this index Q. It will always be less than 100, and in most cases more than 10: a typical range will be between 15 and 35. No decimal points are involved. We further propose to call Q the 'index of productivity', and to calculate it cumulatively from the date of the first exposure to the chance of mating to the birth of successive litters up to the last. This index gives, in a convenient form, a current measure of productivity of pairs of animals, on which selection can be based.

An Unusual Strain of *Escherichia coli* in Septicæmia as an example of the Transformative Effect of Symbiosis

A 54-YEAR-OLD male patient was admitted to hospital with signs of septicæmia and obstructive jaundice after having suffered from gall-bladder troubles for the past five years. By blood culture in brain–heart infusion broth a rich growth of a highly polymorphous Gram-negative organism was obtained (Fig. 1, top) which gave the typical biochemical reactions of an *Escherichia coli* and a positive hæmagglutination test. The macroscopic appearance of the colonies also did not differ from a slightly mucoid *E. coli* culture. No dwarf colonies were found. The polymorphism (filaments with broad swellings, globular and club-shaped forms) was most marked on a culture 24–48 hr. old on 5 per cent rabbit blood agar. After three days the majority of the filaments had broken up into chains of rods and the bizarre forms had disappeared. This aberrant morphology persisted for ten months if the strain was subcultured only on blood agar. After this time it grew in more or less uniform short filaments. If subcultured exclusively on plain agar, it reverted after five months to the typical size and shape of *E. coli*. No morphological change could now be brought about by transferring it from plain to blood agar.

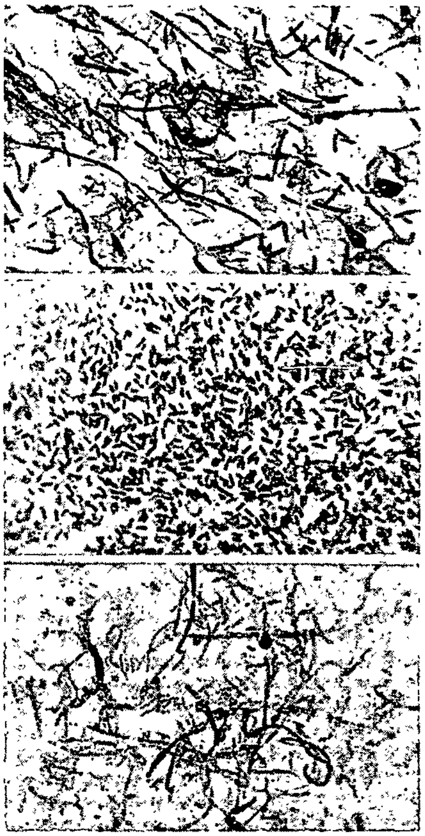

Fig. 1. Top, *E. coli* from blood, shortly after isolation, showing filamentous and swollen forms in a 24-hr. culture on blood agar; middle, bacillary form of the same strain, as in top, after five months subculturing on plain agar; bottom, the same bacillary variant as in middle, re-transformed into the aberrant form under the influence of a *Paracolon* strain. (× *c.* 670)

The patient's serum agglutinated the strain up to a dilution of 1/5,000, but the usual routine agglutinations (*Salmonella*, *Proteus X*, *Brucella* and *Leptospira*) were negative. Fifty control sera gave either negative results or titres below 1/100.

The strain was forwarded to the Statens Serum Institute, Copenhagen, for further investigation. The *coli H*-antigen 6 was found while the *O*-antigen could not be determined.

As a cholecystography showed an obstruction of the gall bladder, the patient was operated on and two stones removed from the common bile duct. Cultures on McConkey plates from bile obtained from the inflamed gall bladder during operation revealed the presence of scanty colonies of the same polymorphous *E. coli* as found in the blood together with many colonies of a quite different *Enterobacterium*. The latter one grew in short rods of uniform size and shape, formed on iron-triple sugar agar acid and gas only at the butt, utilized citrate, split urea and produced ammonia and indole but no hydrogen sulphate. It readily formed acid and gas from glucose and mannitol, but slowly from lactose and salicin. Saccharose, adonitol and inositol were not fermented. The hæmagglutination test was negative. On solid media, the growth was luxuriant but otherwise was not characteristic.

This second strain does not fit biochemically into any of the recognized types of Enterobacteriaceae. Belonging to the slow lactose fermenters, it might still be best to call it a *Paracolon bacterium*, although this group has lately been abolished by some authors[1].

The fact that the two strains were found together in the bile suggested the idea that this symbiosis was responsible for the morphological change of the *E. coli*. Therefore, we tried to re-induce the aberrant growth in its daughter strain from plain agar, which had changed back to the typical bacillary form, by culturing it together with the *Paracolon* in a liquid bile medium and by subsequent isolation on McConkey plates. This method failed because the *Paracolon* overgrew and destroyed the *E. coli* within two or three days. In the gall bladder, the *E. coli* was probably protected by mucus and exudate against antagonistic environmental influences, and in the intestines the *Paracolon* might not have been numerous enough to eliminate completely the *coli* strain. Our experiments succeeded, however, as soon as we applied a modified cross-streak technique, generally used for investigating antibiotic effects.

A segment of a blood agar plate was thickly inoculated with the *Paracolon* strain and incubated for two or three days. Now, a suspension of the bacillary *coli* strain was prepared and streaks were drawn with it perpendicularly to the edge of the *Paracolon* growth. Similar streaks were made on a separate blood agar plate as controls. After 24-hr. incubation, the controls showed rich uniform growth without morphological change (Fig. 1, middle). On the plate previously inoculated with the *Paracolon*, the growth of the *E. coli* was considerably inhibited but not completely abolished up to a distance of 20 mm. from the edge of the *Paracolon* growth and became gradually richer farther away. Morphologically, the bacillary variant was re-transformed to its previous filamentous form with its bizarre shapes (Fig. 1, bottom). This transformation occurred in the partly inhibited zone as well as in the uninhibited one.

Yet subcultures from the streaks on a fresh blood agar reverted to the bacillary form after 24 hr. if they were made within the first few days after the transformation into the aberrant form had taken place. If, however, the plates were sealed with 'Plasticine' in order to prevent exsiccation and the *E. coli* was kept in association with the *Paracolon* for three to four weeks, the filamentous phase proved to be much more stable in repeated subcultures on blood agar and it took about one month before it reverted to the bacillary form.

Neither inhibition nor morphological alterations could be induced by this method in a number of typical *coli* strains from stools.

It appeared to be most likely that the morphological change was brought about by a weakly antibiotic substance, probably a colicine[2,3], produced by the *Paracolon* and diffusing through the agar. Filament formation has been observed under the influence of growth inhibitors[4] but the organisms revert rather quickly to their original size as soon as they are brought back to normal conditions. We have seen the same in our transformation experiments of short duration. However, if subcultured on blood agar before a reversion to the bacillary phase occurred, our strain represented a fairly stabilized morphological variation, manifesting itself regularly at a certain period of growth by taking shapes which were similar to the *L* forms of *E. coli*[5]. Yet it did not grow in micro-colonies as is characteristic for true *L* forms. The comparative stability of our variant was obviously brought about by a long-lasting symbiosis with the *Paracolon*. This could be reproduced, to a certain extent, by the association of the two strains for some weeks.

So far as we are aware, this is the first time that the induction of a rather stable transformation of a bacterial strain by its symbiosis *in vivo* with another one has been recognized as such and could be experimentally reproduced. A detailed account of our experiments is to be published elsewhere.

We wish to express our thanks to Dr. F. Ørskov, Copenhagen, for examining the *coli* strain serologically and to Dr. H. Salomon, Haifa, for preparing the photomicrograms.

An Antifungal Substance in the Corn Plant and its Effect on Growth of Two Stalk-rotting Fungi

IN a recent paper on root and stalk rot of field corn in south-western Ontario[1], we reported that stalk-rotting fungi do not invade the stalks of young corn plants. Subsequent experiments have been designed to investigate whether or not young corn stalks contain substances which will inhibit the growth of these fungi. Loomis *et al.*[2] found resistance factors in corn which were effective against the European corn borer, *Pyrausta nubilalis* (Hubn.), as well as *Penicillium chrysogenum* and other organisms. Virtanen *et al.*[3] isolated antifungal factors from wheat, maize and rye which inhibited *Fusarium* sp., *Penicillium* sp. and a wide range of other micro-organisms. In the present communication results are presented which demonstrate that extracts from young corn stalks inhibit growth of two stalk-rotting organisms, *Fusarium moniliforme* Sheld. and *Gibberella zeae* (Schw.) Petch.

Stalks of 52-day-old corn (Pioneer 349) were cut into small pieces and frozen. To 2,000-gm. samples of the frozen material, 1,000 ml. of distilled water was added and the mixture was boiled for 15 min. Juice, extracted from the mixture under pressure, was concentrated to 1,000 ml. by boiling. An ether extract from this juice was assayed for antifungal activity by measuring its effect on growth of *Fusarium moniliforme* and *Gibberella zeae*, which were grown on dehydrated Czapek's agar plus extract for 72 hr. at 25° C. The diameters of the colonies of *Fusarium moniliforme* on eight plates of Czapek's agar (control) and on eight plates of Czapek's agar plus extract averaged 4·10 cm. and 2·23 cm., respectively. This represents an inhibition of growth of 45·6 per cent caused by the extract.

Growth of *Gibberella zeae* was inhibited by 22·5 per cent.

In ten other lines of corn investigated, inhibition of *Fusarium moniliforme* ranged from 56·5 to 63·9 per cent.

The results of these experiments strongly suggest that stalks of young corn are not attacked by *Fusarium moniliforme* or by *Gibberella zeae* because of the presence of an antifungal substance in the young stalks.

Balanus tulipiformis Ellis on the Atlantic Coast of France

THE presence of *Balanus tulipiformis* Ellis on the Atlantic coast of Europe was recently recorded for the first time[1]. It was there noted that this species had been observed on the south-west coast of France from 1956.

It has since transpired that among the barnacles in the Musée de la Mer, Biarritz, there are two lots of *B. tulipiformis*, both found considerably earlier. These specimens had not been recognized as such, and had been labelled *B. amphitrite* Darwin. Samples from each of these exhibits have been examined by Dr. J. P. Harding, who has confirmed their identification as *B. tulipiformis*.

The earlier lot consists of about 30 young or half-grown specimens which had been thrown up on the beach at Messanges (Landes). They were collected by M. Paul Arné, some living and some dead, between 1923 and 1933. In the latter year, M. Arné left Messanges to take up the post of director of the newly opened Musée de la Mer, Biarritz, taking his collections with him. The later exhibit is a group of 10 or so large specimens, all joined together, which was found on a piece of rock brought up with a crayfish trap off Biarritz in 1950.

It is thus established that a quarter of a century has elapsed since *B. tulipiformis* was first found on the south-west coast of France.

Facultative Parasitism and Dietary Change in *Harmolita hyalipenne* Walker

DIETARY change from carnivory to phytophagy has been previously reported from four Eurytomidae; by Nielson[1] from Denmark for an unidentified species of *Eurytoma* parasitic on the larvæ of *Cryptocampus angustus* Htg. in willow twigs; by Rimsky-Korsakow[2] for *Harmolita inquilinum* (the U.S.S.R.) parasitic on *H. rossicum* in the stems of rye; and by Phillips[3] for *Eurytoma pater* Girault and *E. parva* Girault[4,5]

Table 1

Square No.	1	2	3	4	5	6	7	8	9	10	11	12	13	14	Controls

No. of galls	73	0	0	0	53	0	0	4	36	18	0	2	0	0	0	0	0

parasitic on the wheat joint worm *H. tritici* Fitch in the United States. In each case the eurytomid larva parasitizes its stem-living host larva, and having destroyed this becomes phytophagous in order to obtain sufficient nutriment for the completion of its development.

During an investigation into the species of Eurytomidae infesting the couch grass *Agropyron repens* Beauv. in Britain, *Harmolita graminicola* Giraud was found to be the main species inducing the formation of apical stem galls, while *H.* (*Eurytoma*) *hyalipenne* exhibited a facultative parasitism and played only a minor part in gall formation.

The female *H. graminicola* oviposits in June or July in the zone of elongation immediately below the apical meristem of the couch grass, and the single larva emerging from the egg feeds on the plant tissue inducing the formation of a fusiform apical gall. Its larva is bright yellow in its later instars and is easily distinguished from the white late instar larva of *H. hyalipenne*.

H. hyalipenne reaches a peak of emergence a few days later than *H. graminicola*, the females laying their eggs immediately above the final node of the stem which, however, usually forms the base of a young gall of *H. graminicola*, and, under natural conditions, the infested stems are selected for oviposition. The eggs are dark brown in colour, and from each an extremely active larva emerges which immediately attacks and destroys the gallicolous larva of *H. graminicola*, this still being in an early instar. The amount of food obtained from this brief parasitic period is small and insufficient for future development so that the larva then turns to the plant tissue, which it consumes until the onset of diapause.

It was decided in 1958 to test experimentally whether this parasitic part of the life-cycle was essential, since collections made in the field showed occasional galls in which there was no trace of the remains of *H. graminicola* larva, while an active *H. hyalipenne* was feeding inside the gall.

A series of square-yard samples of couch grass were cleared of galls by careful inspection and cutting the grass of the growth of the previous years. Over each square a butter-muslin cover was placed mounted on a wooden frame, and a known number of male and female *H. hyalipenne* which had been reared in the laboratory were then introduced into each square in July and allowed to oviposit on the stems.

After two months the covers were removed and the grass from each square cut and examined in the laboratory, where the galls were counted, the figures being shown in Table 1.

From this it is apparent that if *H. hyalipenne* females are deprived of stems infested by the larvæ of *H. graminicola* they will still continue to oviposit and their larvæ develop fully although unable to undergo a parasitic phase in their life-cycle. The galls which these larvæ produce are identical with those of *H. graminicola*.

When considering the life-cycles of the Eurytomidae where dietary change was then known, Gahan[6] inferred that phytophagy was a recent specialization arising from a parasitic life-cycle. Although *H. hyalipenne* shows a similar dietary change, its ability to dispense with parasitism in its larval stages and to develop normally by phytophagy indicates that the reverse may be true and that larval parasitism in this group is a more recent specialization.

GENETICS

Selection for Relationships Opposite to those predicted by the Genetic Correlation between Two Traits in the House Mouse (*Mus musculus*)

THE majority of the concepts of population genetics used in predicting possible progress in livestock breeding are derived from the known behaviour of single genes. An exception to this is the concept of the genetic correlation between two traits which is based on the statistical partitioning of their variances and covariance[1]. The genetic portion of these variances and covariance is then used to estimate a probable change in one trait when the second trait is selected for. Falconer[2] has indicated the validity of this process for a particular case in that he obtained similar values for the genetic correlation between length of tail and body-weight in mice of six weeks of age from an experiment in which the response of each was measured when the other was selected for.

The genetic correlation in Falconer's experiment could be the result of pleiotropy or of linkage. If it resulted from pleiotropy of only a proportion of the genes concerned, then it should be possible to select for genes which affect tail length or body-weight only. A suitable selection method could then produce results opposite to those predicted by the genetic correlation. Some early results from such a selection experiment are available.

Initial stocks were obtained by inter-crossing the inbred lines *A^w C.57.Bl.* and *CBA* obtained from the Animal Genetics Section, Commonwealth Scientific and Industrial Research Organization, Sydney. All possible reciprocal crosses were made and the resulting progeny were then inter-crossed. Selection was started on mice from a second inter-crossing and made between all mice of the first litter in each generation with the only restriction being the avoidance of sib-matings. Males and females were selected separately and two litters were bred from each mating.

Selection was made on the deviations of the actual body-weight at six weeks from the expected value.

*Estimated from genetic regression (see text), ♂♂; $y = 2{\cdot}5X - 0{\cdot}7$
♀♀: $y = 4{\cdot}2X - 17{\cdot}5$

†Eighteen matings in the final intercross, four matings in each selection generation

This expected body-weight was estimated from the observed length of tail by use of the regression of body-weight on length of tail. Lines for positive and negative deviations were selected and for the first three generations the regression used was that calculated from the litters of previous generations. Subsequent selection has been by use of the regression within the first three generations of the positive and negative lines. Regressions for males and females were calculated separately.

Table 1 shows the length of tail and body-weights at six weeks for the first litters of six selection generations. The standard deviations shown are those for the offspring of the sixth generation. Selection for positive deviations has resulted in mice with shorter tails and greater body-weight than those arising from selection for negative deviations.

Estimates of the genetic correlations made from the initial crosses gave values of 0·66 for males and from 0·77 to 0·92 for females. For this type of estimate these values are in reasonable agreement with those of 0·57 and 0·62 obtained for both sexes by Falconer[2]. The genetic components of variance and covariance used to obtain the correlation were also used to calculate a regression of body-weight on length of tail. It is this regression which has been used to obtain the expected values of body-weight shown in Table 1.

These results show that it is possible to make fairly rapid progress in selection for relationships between two traits different from those predictable from the expected correlated response. An explanation based on a hypothesis that a proportion of the genes are pleiotropic for length of tail and body-weight is reasonable, but the alternative explanation of linkage of the genes concerned and selection of appropriate recombinants must be considered in this experiment. Mather and Harrison[3] have concluded that an observed correlated response in *Drosophila melanogaster* was the result of polygenic linkage. This is less likely in mice with their greater number of chromosomes and hence a lesser chance of any two genes being linked. However, if pleiotropy is concerned, then further selection for tail length alone should eventually give the appropriate correlated response of body-weight as the pleiotropic genes should still be present. If linkage was the cause of the original correlation and these linkages have been broken, as suggested by Mather and Harrison[3], then no correlated response of body-weight should follow continued selection for length of tail alone. These alternative possibilities are now being tested.

Whatever the underlying cause, it is clear that in this case the presence of a genetic correlation does not preclude the possibility of a rapid response to selection for various combinations of the correlated traits. Whether this is true in other cases may well depend on whether or not there is a unique physiological basis for the traits measured.

I should like to acknowledge the advice and encouragement of Prof. A. L. Rae. This work was supported by a grant from the New Zealand Department of Scientific and Industrial Research.

PSYCHOLOGY

Association between Psychomotor Behaviour and Delinquency

IN 1948, Davis[1] reported experimental evidence of significant association between manner of movement of controls in a simulator cockpit and (*a*) neurotic syndromes and (*b*) accident proneness among pilot trainees. In 1955, Venables[2] reported experimental results confirming Davis's finding (*a*) above, also (*c*) non-significant correlation of psychomotor response variable with general intelligence and (*d*) significant association of response pattern, on a task of graded difficulty, with subsequent job-dismissal in a small industrial group ($n = 18$).

The relation between psychomotor behaviour in this test situation (replicating the procedure described by Venables[2]), and subsequent delinquency (the criterion of delinquency, by Service classification, includes minor offences not thus classifiable by civil usage) in a large sample of Royal Air Force recruits to a relatively low-skilled trade, has been studied in a research for the Air Ministry, with results summarized below. (Theoretical implications are the subject of a separate report.) Initially, the finding of non-significant correlation between general intelligence and the psychomotor variate, and of the continuous unimodal distribution of the variate, was confirmed for the Royal Air Force population. Venables' preferred variate was the ratio of amplitude of manual responsive movement to time taken in making the movement; this measure has been used in logged form. The subject moves a knob in a slot, right or left and back to centre, in response to visual signals. The signals are presented in three series, of which the first (*A*) and last (*C*) are similar and relatively easy and the second (*B*) difficult for all subjects. The difficulty of response to *B*-series lies in the speed and complexity of presentation of the signals in the series as a whole. The stimuli for the responses which are scored, and the type of responsive movement required, are the same in all three series. The subject does not see the record of his movements.

Response to the three series tends to be made at a characteristic score-level, so that the series scores are correlated positively with a high degree of significance (product-moment r in a 20 per cent random sample of all subjects tested to a given date with $n = 251$ were: AB, $+0{\cdot}88$; AC, $+0{\cdot}87$; BC, $+0{\cdot}87$). Some individuals tend to reduce and some to increase score with change of difficulty of task; the direction of change has been found to be significantly associated with temperamental factors in the previous researches quoted. In this investigation both the general score-level and the degree and direction of the difficulty gradient were found significantly predictive of delinquency (service plus civil) over a period of up to 19 months subsequent to the administration of the test.

The results of two analyses are shown below, the first based on records of all tested entrants to training in the trade in question, over a given period ($n = 601$), the second a more detailed analysis of a smaller sample ($n = 157$). The crime record criterion was on a dual basis: (1) number of convictions, and (2) penalty awarded; categories ranged from zero on both counts to 3 or more convictions for offences of which at least one was indictable or penalized as serious by the Service authority. Psychomotor-test mean scores and variances were calculated for all groups and various combinations of groups. In the first study the non-delinquent group included: (1) men without record of conviction; (2) men convicted of one minor Service crime only; (3) men withdrawn from trade training for technical reasons only. The delinquent group included (1) men with several or serious offence records; (2) men withdrawn from trade training owing to unsuitability of character. Mean score differences were significant between the delinquent/non-delinquent groups but not within these groups. With the accumulation of additional records, the later study was restricted to group (2) of the non-delinquents and group (1) of the delinquents. More than 80 men were subjects of both studies, many appearing in different crime groups on the two occasions, owing to accumulation of individual crime records.

Table 1. PSYCHOMOTOR TEST SCORES OF NON-DELINQUENT AND DELINQUENT GROUPS: INITIAL SERIES AND DIFFICULTY GRADIENT SCORES

Series	Non-delinquents $n = 567$ Mean	Non-delinquents $n = 567$ Variance	Delinquents $n = 34$ Mean	Delinquents $n = 34$ Variance	P of difference between means
A	195·6	1,494	220·1	1,694	$< 0{\cdot}001$
$A-B$	3·24	420·4	13·03	629·2	$< 0{\cdot}05$
$B-C$	−6·39	438·7	−14·03	346·8	$< 0{\cdot}02$

Table 2. PSYCHOMOTOR TEST SCORES OF NON-DELINQUENT AND DELINQUENT GROUPS VARIOUSLY CLASSIFIED: DIFFERENCES BETWEEN MEAN SCORES ON INITIAL SERIES AND DIFFICULTY GRADIENTS

Groups compared $n(1)$–$n(2)$	One minor crime with the rest 107/50		One crime with multiple crime 125/32		Minor crime with serious crime 119/38	
Series	Difference between $\bar{x}$	P	Difference between $\bar{x}$	P	Difference between $\bar{x}$	P
A	−−19	$<0{\cdot}01$	−25	$<0{\cdot}01$	−22	$<0{\cdot}01$
$A-B$	− 5·6	$>0{\cdot}05$	− 7·4	$>0{\cdot}05$	− 9·5	$<0{\cdot}01$
$B-C$	+ 3·5	$>0{\cdot}05$	− 0·7	$>0{\cdot}05$	+ 6·2	$<0{\cdot}01$

It was found that the delinquent groups differed significantly from the non-delinquent both in manner of reaction to reduction of task difficulty ($B - C$ score), confirming Venables's finding[2], and also, more significantly, on all primary series scores, of which only *A* score is shown in Tables 1 and 2. They also differed significantly in manner of reaction to increase in task difficulty.

The psychomotor variate was interpreted by Davis as anticipatory tension, closely related to anxiety. It seems that anxiety is relatively chronic or diffuse in relation to the easier task, relatively specific or objective in relation to the more difficult task. By these investigations, association is established between psychomotor behaviour and delinquency, the association being interpreted in terms of level of chronic or diffuse anxiety and manner of reaction to change of specificity of the source of anxiety.

Effect of Reduction of Stimulation on Consumption of Food, Intake of Water and Weight of Body in Rats

RECENT work on factors determining the amount of general activity in animals indicates that such activity is related to: (*a*) the presence of stimuli previously associated with the diurnal cycle; (*b*) stimulus variety in the environment. However, the evidence is suggestive rather than conclusive, the main difficulty arising from the lack of specifiability and measurement of 'general' activity. We therefore investigated a readily measurable behaviour pattern, namely, eating and drinking.

Two hooded male rats, approximately 4 months old at the beginning of the experiment, were tested over a period of six months. The apparatus consisted of a cage measuring 13½ in. long, 9½ in. high and

8 in. wide, fitted with a lever. When the lever was pressed, powdered food (0·025 gm.) was delivered from a concealed food hopper into a recessed food trough placed to the left of the lever. The apparatus could be enclosed in a sound-proofed box which was suspended in a sound-proofed chest. The apparatus (including control equipment) stood in the experimenter's office. The inner box was ventilated by an air pump and was constantly illuminated by a 15-watt lamp. The apparatus and subjects were kept for 4 days inside the chest, and then for 4 days the apparatus was placed, exposed, on top of the chest. Thus the animal was alternately subjected to reduction (environmental restriction) and variety of stimulus.

Table 1 gives the results for animals 1 and 2 respectively. Each trial period lasted for 4 days. The results cover the last 40 days of the experiment and consist of the mean daily frequency of pressing of the lever, the mean daily amount of food consumed (gm.), the mean daily amount of water drunk, and the change in weight during the trial, under each of the experimental conditions.

Statistical tests support the conclusion that the effect of reduction of stimulation (restricted environment) is to reduce the animal's food consumption and intake of water, as well as to inhibit temporarily gain in weight. During the restricted environment phase of the experiment, the food consumption of animal 1 fell off by 25·7 per cent and intake of water by 15 per cent. The food consumption of animal 2 fell off by 27·2 per cent and intake of water by 12·4 per cent.

Threshold Values for Taste in Monozygotic Twin Calves

ELECTROPHYSIOLOGICAL studies have shown that specific taste receptors are distributed in definite topographical arrangements on the tongue of man and laboratory animals[1,2]. More recently, similar studies have been extended to include domesticated ruminants[3]. Taste discrimination has been demonstrated in a variety of laboratory animals[4,5] and using this type of preference test, threshold values for rejection and acceptance of a variety of sapid substances have been established for a number of different species.

Discrimination tests for taste have now been carried out using monozygotic twin calves as subjects. Monovular calves were chosen for investigation for two reasons; first, in order to extend knowledge of sensory discrimination and especially of the sense of taste to another species, and secondly, to find out whether monovular cattle twins show the same close similarity in the inheritance of physiological sensory thresholds as they do for anatomical and biochemical factors[6].

The 'two-choice' discrimination tests for cattle were carried out in a manner like that devised for the goat[7]. Each calf was kept in a similar specially fitted stall, and feeding and management were standardized so far as possible. The front of each animal's stall allowed access to two identical polythene buckets suitably fixed at ground-level; normally, these buckets were kept filled with tap water. For the test a known concentration of test substance in solution in tap water was placed in one bucket and tap water only in the other bucket. The position of the test solution was reversed the next day to offset any bias due to visual or behavioural cues. For each single concentration of solution the aggregate amount consumed in the right and left position was used in assessing the results. The amount of test solution taken during the two test periods of nine hours on consecutive days was calculated as a percentage of the total fluid intake, that is, volume of test solution ingested and volume of water ingested.

The results for the whole group of calves and different sapid solutions are presented graphically in Figs. 1–4. It can be seen that high concentrations of test substance are usually rejected almost completely, the small amounts taken being only sufficient to stimulate the animals' taste receptors. The rejection threshold has been placed arbitrarily at the lowest concentration where not more than 20 per cent of the total fluid intake has been consumed. The ideal acceptance threshold, the level at which animals do not discriminate between test solution and tap water, would be the level when 50 per cent of the total fluid intake is the test solution. In practice this value probably lies between 40 and 60 per cent of the total fluid intake. The mean values for rejection and acceptance thresholds for all calves for the four normal taste modalities of sweet, sour, salt and

Table 1. GUSTATORY THRESHOLDS OF CALVES TO THE FOUR TASTE MODALITIES OF BITTER, SOUR, SALT AND SWEET. THE NUMBER IN BRACKETS REFERS TO THE NUMBER OF ANIMALS TESTED

Substance		Threshold concentration (moles)	
		Rejection	Acceptance
Quinine dihydrochloride	(12)	0·000097	0·000024
Acetic acid	(8)	0·026	0·0083
Sodium chloride	(8)	0·42	0·105
Glucose	(8)	—	1·11

bitter are shown in Table 1. In the case of sweet (glucose) taste sense there does not appear to be a true rejection threshold value.

The threshold values obtained between the different animals of the group shows a very much wider range than that shown between the individuals of a twin-set. The mean of the results for all the calves tested is plotted in Figs. 1–4 together with the values for the individuals of a monozygous twin-set. In an attempt to make the tests more rigorous and to eliminate environmental factors the individual members of the set of twin calves shown in Figs. 1–4 were separated by a distance of 15 miles, one of each set being housed at Potters Bar and the other at Camden Town. (The broken line in Figs. 1–4 is the mean of all the calves tested. The open and closed circles are the results obtained from the individuals of a monovular twin set, one of which was housed at Potters Bar and the other at Camden Town.) Furthermore, the test solutions were offered on different days at Potters Bar and Camden Town and the personnel dealing with the animals was different at the two places. The 'within-set' taste discrimination and consequently the close similarity of gustatory thresholds of calves is shown in Figs. 1–4. It would appear from the close relationship of the 'within-set' differences obtained that taste discrimination was almost entirely genetical in origin, and that environmental factors play only a minor part in this type of behavioural reaction.

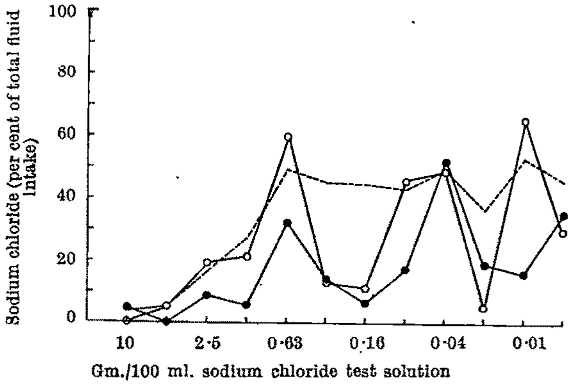

Fig. 1. Sodium chloride taste preference tests

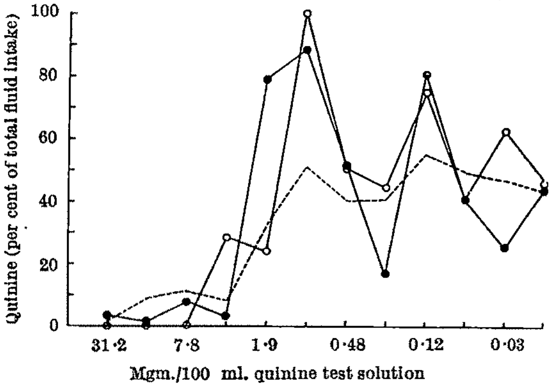

Fig. 2. Quinine taste preference tests

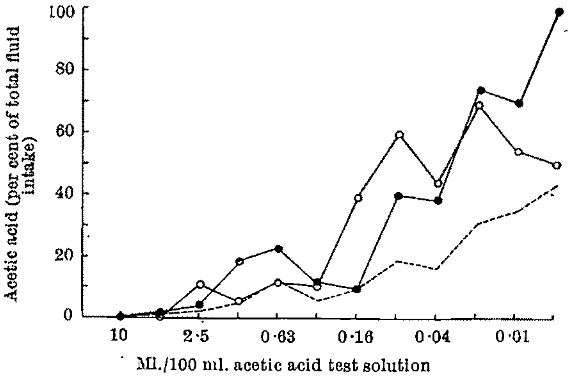

Fig. 3. Acetic acid taste preference tests

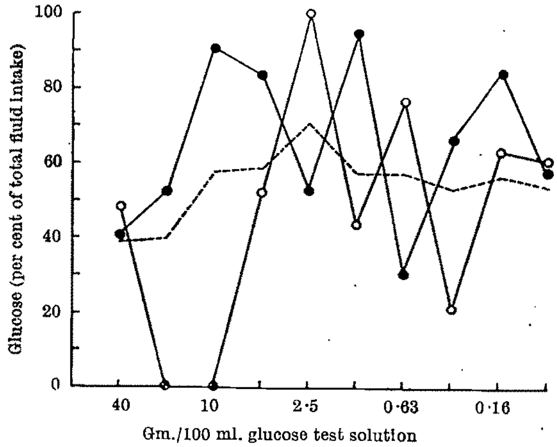

Fig. 4. Glucose taste preference tests

These results afford further evidence of the value of monozygotic twins as subjects for experimental research in the larger animals. Monovular twin cattle will obviously be the experimental animals of choice in the design of experiments to study physiological sensory mechanisms and nervous pathways in ruminants, for each pair will provide a control and experimental subject, thus reducing the high costs associated with experimental investigations of these large ungulates.

This work will be reported in detail elsewhere. We wish to express our thanks to the Agricultural Research Council for financial assistance and to B.O.C.M., Ltd., for generous supplies of animal foods.

Institution of Mechanical Engineers, Lubrication Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Informal discussion of the paper by Mr. N. F. Rieger: "An Experimental Investigation of the Pressurized Air-Lubricated Journal Bearing in the High-Speed Range".

Society for Analytical Chemistry, Biological Methods Group (joint meeting with the Biometric Society, in the Small Lecture Theatre, London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6.30 p.m.—Scientific Papers.

Society of Chemical Industry, Plastics and Polymer Group (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Mr. F. R. G. Gimblett: "Polymers and Derivatives of Phosphonitrile Chloride".

Wednesday, February 4

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Dr. D. G. R. Bonnell: "The Mechanization of Building Constructional Processes" (Alfred Bossom Lecture).

Institute of Fuel (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 5.30 p.m.—Mr. D. Anson: "A Radioactive Corrosion Probe".*

Institute of Petroleum (at 61 New Cavendish Street, London, W.1), at 5.30 p.m.—Mr. D. H. Tullis, Mr. L. C. Neill and Mr. A. T. Henderson: "Control of Marine Organisms in a Salt-Water Cooling System".

University of London (in the Anatomy Lecture Theatre, University College, Gower Street, London, W.C.1). at 5.30 p.m.—Prof. G. De Santillana (Massachusetts Institute of Technology): "Space in Antiquity and the Renaissance".* (Further lecture on February 6.)

Society of Chemical Industry, Food Group—Nutrition Panel (at 14 Belgrave Square, London, S.W.1), at 6.15 p.m.—Dr. G. D. Rosen: "Practical Implications of the Laboratory Evaluation of Protein Quality".

British Institution of Radio Engineers, Computer Group (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6.30 p.m.—Inaugural Meeting.

Society for Analytical Chemistry (in the Meeting Room of the Chemical Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Meeting on "The Estimation of Pesticide Residues".

Royal Institute of Chemistry, London Section (joint meeting with the South-West Essex College of Technology Chemical Society, at the South-West Essex College of Technology, Forest Road, London, E.17), at 7.30 p.m.—Dr. S. F. Birch: "Petroleum Chemicals".

Thursday, February 5

University College (in the Anatomy Theatre, Gower Street, London, W.C.1), at 1.15 p.m.—Mr. A. J. Lloyd: "Water for the Swiss Jura".*

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. A. H. Cooke, Mr. J. H. E. Griffiths, Mr. B. R. Judd, Mr. R. Lazenby, Mr. F. R. McKim, Mr. J. Owen, Mr. J. G. Park, Mr. M. F. Partridge and Mr. W. P. Wolk: "Exchange Interactions in Antiferromagnetic Salts of Iridium. 1: Paramagnetic Resonance Experiments. 2: Magnetic Susceptibility Measurements. 3: Theory of the Interaction".

Institute of Refrigeration (at the Institute of Marine Engineers, The Memorial Building, 76 Mark Lane, London, E.C.3), at 5.30 p.m.—Dr. H. J. Goldsmid: "Thermoelectric Cooling".

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. T. H. Mason, Dr. P. D. Aylett and Mr. F. H. Birch: "Turbo-Generator Performance under Exceptional Operating Conditions."

Royal Anthropological Institute (at 21 Bedford Square, London, W.C.1), at 5.30 p.m.—Dr. J. H. M. Beattie: "Neighbourliness in Bunyoso".

University of London Institute of Education (in the Assembly Hall, Malet Street, London, W.C.1), at 5.30 p.m.—Prof. L. J. Lewis: "Partnership in Oversea Education"* (Inaugural Lecture).

Royal Aeronautical Society (at Hatfield Technical College, Hatfield, Herts), at 6.15 p.m.—Mr. J. L. P. Brodie: First Halford Memorial Lecture.

Society of Chemical Industry, Microbiology Group (joint meeting with the Agriculture Group, at 14 Belgrave Square, London, S.W.1), at 6.15 p.m.—Dr. Bond and Mr. R. Cooper: Two papers on "Nitrogen Fixation".

Polarographic Society (at "The Duke of York", 8 Dering Street, London, W.1), at 7 p.m.—Informal Discussion Meeting on "Some Polarographic Problems Encountered in the Semi-Conductor Field" introduced by Dr. V. J. Jennings.

Royal Institute of Chemistry, London Section (joint meeting with the Kingston Technical College Chemical Society, at the Kingston Technical College, Fassett Road, Kingston), at 7 p.m.—Prof. M. Stacey, F.R.S.: "Fluorinated Hydrocarbons".

Friday, February 6

University of London (in the Meyerstein Lecture Theatre, Westminster Medical School, Horseferry Road, London, S.W.1), at 5.15 p.m.—Prof. L. T. Samuels (University of Utah): "Studies of Steroid Biosynthesis in Testicular Interstitial Cells".*

Institution of Electrical Engineers, Medical Electronics Discussion Group (at Savoy Place, London, W.C.2), at 6 p.m.—Discussion on "Problems of Storing Transient Phenomena for Subsequent Analysis" opened by Dr. P. Bauwens and Mr. P. Styles.

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. V. E. Cosslett: "Microscopy with X-Rays".

Saturday, February 7

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Mr. R. A. Skelton: "Captain James Cook's Voyages in the South Seas and their Scientific Value".*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Research Assistant (Computational) (preferably with a degree and interested in the application of numerical methods to chemical problems) in the Department of Chemistry—The Registrar, The University, Manchester (February 7).

Senior Lecturer or Lecturer (with special qualifications in pure mathematics) in Mathematics—The Registrar, The University, Manchester 13 (February 7).

Pig Breeding Advisor (agricultural graduate with good post-graduate experience in the scientific aspects of animal breeding and a sound practical knowledge of pig breeding), for duties concerned with advising at farm level on pig breeding problems including those arising in connexion with pig recording and progeny testing—The Establishment Officer, Pig Industry Development Authority, Pida House, 15–17 Ridgmount Street, London, W.C.1 (February 10).

Senior Research Assistant (preferably with a knowledge of electron optics and vacuum physics), for experimental research on the aberrations of electron lenses—The Secretary of the Department of Physics, Cavendish Laboratory, Free School Lane, Cambridge (February 14).

Lecturer (with an honours degree in zoology, specialized in agricultural entomology, and experience in pest control and plant protection) in Entomology in the School of Agriculture, Kumasi College of Technology—The Council for Overseas Colleges, 12 Lincoln's Inn Fields, London, W.C.2 (February 18).

University Assistant Lecturer (preferably specialized in applied mathematics and theoretical physics) in Mathematics—The Secretary of the Appointments Committee of the Faculty of Mathematics, The Arts School, Bene't Street, Cambridge (February 18).

Lecturer, an Assistant Lecturer, and Research Fellows in the Department of Physics—The Deputy Registrar, The University, Birmingham 15 (February 19).

Assistant Lecturer in Geography—The Registrar, The University, Leicester (February 21).

Assistant Lecturer in the Department of Agriculture (Crop Husbandry)—The Registrar, University College of Wales, Aberystwyth (February 21).

Chair of Geology—The Registrar, The University, Leicester (February 21).

Research Assistant (preferably with experience in electron microscopy, electronics and vacuum physics), to operate and maintain a Siemens electron microscope in the Metal Physics Group of the Cavendish Laboratory—The Secretary of the Department of Physics, Cavendish Laboratory, Cambridge (February 21).

Research Fellows (Ph.D. standard, with special aptitude for research in high or low energy nuclear physics) in Experimental or Theoretical Nuclear Physics—The Registrar, The University, Liverpool (February 21).

Chair of Mathematics (Theoretical Mechanics)—The Registrar, The University, Southampton (February 28).

Lecturer in Zoology in St. Salvator's College—Joint Clerk to the University Court, College Gate, St. Andrews (February 28).

Lecturer or Assistant Lecturer in Botany at the University College of the West Indies—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (February 28).

Reader in Classical Archæology—The Secretary of Faculties, University Registry, Oxford (February 28).

William Cochrane Chair of Metallurgy tenable at King's College, Newcastle-upon-Tyne—The Registrar, University Office, 46 North Bailey, Durham (February 28).

Lecturer in Physics—The Secretary and Registrar, The University, Southampton (March 4).

Lecturer in Botany at the University College of Rhodesia and Nyasaland—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (March 6).

Lecturer (qualified in the field of palæontology, particularly micropalæontology) in Geology at Victoria University of Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, March 9).

POSTDOCTORAL FELLOW (with a Ph.D. degree in physical chemistry, preferably high polymer chemistry, radiation chemistry or some branch of reaction kinetics) IN THE DEPARTMENT OF PHYSICAL CHEMISTRY—Prof. F. S. Dainton, School of Chemistry, The University, Leeds (March 15).

RESEARCH FELLOWS (2) IN THE DEPARTMENT OF NUCLEAR PHYSICS, Research School of Physical Sciences, Australian National University —The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, March 16).

SENIOR LECTURER (with an honours degree in engineering and preferably some knowledge or experience of industrial engineering) IN MECHANICAL OR INDUSTRIAL ENGINEERING at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, March 16).

IMPERIAL CHEMICAL INDUSTRIES RESEARCH FELLOW IN CHEMISTRY, OR PHYSICS—The Secretary, The University, Exeter (March 23).

LECTURER IN BOTANY (PLANT PHYSIOLOGY) at Victoria University of Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, March 31).

SENIOR LECTURER IN SOIL MICROBIOLOGY, and a SENIOR LECTURER IN FARM MANAGEMENT at the Institute of Agriculture, University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, March 31).

HEAD (male of high scientific attainment with wide research experience either in soil science or in a relevant basic subject such as physical chemistry) OF THE DEPARTMENT OF PEDOLOGY—The Secretary, Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen (April 6).

LECTURERS (2) IN BOTANY—The Secretary, The Queen's University, Belfast (April 10).

HEAD (with high qualifications and considerable research experience) OF THE DEPARTMENT OF PHYSIOLOGY—The Director, Institute of Animal Physiology, Agricultural Research Council, Babraham Hall, Babraham, Cambridge (April 30).

LECTURER (with a good honours degree in zoology and preferably some experience of teaching and research) IN ZOOLOGY at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Hong Kong, May 30).

ASSISTANT LECTURER (graduate, preferably with teaching experience in physics) IN PHYSICS—The Clerk to the Governing Body, Borough Polytechnic, Borough Road, London, S.E.1.

CHEMIST or BIOCHEMIST (preferably with postgraduate experience) IN THE DEPARTMENT OF RADIOCHEMISTRY, for fundamental biochemical research involving the use of radioactive isotopes, and in particular C^{14} and tritium—The Secretary, National Institute of Research in Dairying (University of Reading), Shinfield, Reading, quoting Ref. 59/2.

HEAD (graduate of a British university and experience in university teaching and research) OF THE DEPARTMENT OF CIVIL AND MECHANICAL ENGINEERING—The Clerk to the Governing Body, Battersea College of Technology, Battersea Park Road, London, S.W.11.

LECTURER IN MATHEMATICS, to teach up to B.Sc. General Degree standard, and an ASSISTANT LECTURER (with a degree or equivalent and preferably industrial and/or teaching experience) IN TELECOMMUNICATIONS, to teach up to the Final Certificate of the City and Guilds of London Institute and the R.T.E.B. Radio and Television Servicing Certificates—The Clerk to the Governors, Northern Polytechnic, Holloway, London, N.7.

RESEARCH ASSISTANTS (ACADEMIC) (with a good degree and preferably some research experience) IN THE PHYSICS DEPARTMENT, to take part in research in the field of vacuum physics and photoelectronics applied to nuclear physics, astronomy, etc.—Prof. J. D. McGee, Imperial College, London, S.W.7.

TECHNICIAN (with experience in bacteriological work) IN THE VIRUS RESEARCH LABORATORY, Lodge Moor Hospital—Prof. C. H. Stuart-Harris, The Royal Hospital, Sheffield 1.

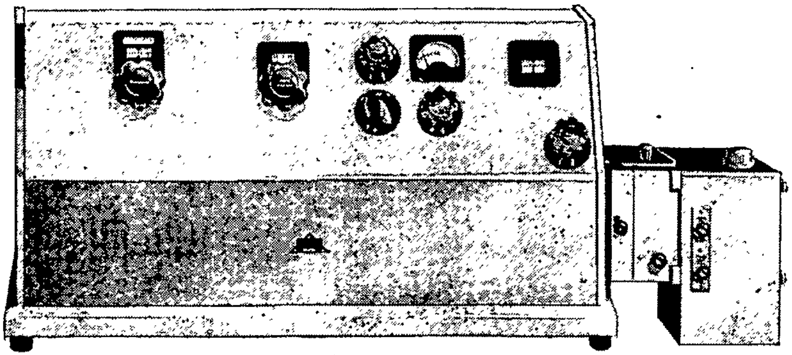
(Continued overleaf)



SP. 500 SPECTROPHOTOMETER

186 mμ

The Unicam SP.500 Ultraviolet and Visible Spectrophotometer is now fitted with a high grade silica prism which extends the useful working range of the instrument beyond 200 mμ to the region of atmospheric absorption at 186 mμ.
Better prism transmission gives the important advantage of reduced slit widths with a consequent reduction in stray light and increase in resolution, a facility which is especially valuable in the 190-240 mμ region.
A redesigned slit mechanism, in which static friction is virtually eliminated, allows the lowest slit widths to be accurately set and reproduced. Combined with the better transmission of the new prism, this feature greatly increases the scope of the instrument for high resolution determinations at the lower end of the spectral range.

The Faraday Society

The Council of the Faraday Society have accepted an invitation from the National Research Council, Ottawa, and Canadian Industries to hold a

GENERAL DISCUSSION in
KINGSTON, ONTARIO,
from September 2–4, 1959.

The subject will be

CRYSTAL IMPERFECTIONS AND THE CHEMICAL REACTIVITY OF SOLIDS

In addition visits to various universities and industrial concerns are being planned.

Any members who are interested in attending or contributing should make early contact with the Secretary, The Faraday Society, 6 Gray's Inn Square, London, W.C.1.

GRIFFIN
Established in 1820

THE BIRTH OF THE STEAMBOAT

H. PHILIP SPRATT, B.Sc., A.S.M.E.

An accurate historical account of the ideas, experimentation and persistent effort which culminated in the achievement of the steamboat some 150 years ago—in those vessels which plied at from three to six knots upon the inland and coastal waters of Europe and America, and later across the open seas.

The author, who is in charge of the steamship collections at the Science Museum, London, has had unique opportunity of collecting his material for, in addition to the considerable resources available in London, Greenwich and Paris, he has, in the interests of research, travelled widely in Europe, Scandinavia, Soviet Russia and the United States, and this has enabled him to make an authoritative contribution to scientific history.

This work breaks new ground and will remove some misconceptions as to the origin of the steamboat, which in fact dates back much further than is generally realised.

CHURCHILL COLLEGE, CAMBRIDGE

ON January 24 the University of Cambridge passed without opposition a grace giving recognition to the proposed Churchill College as an approved foundation from the first day of the first term in which it admits students. Although outwardly no different from any other congregation in the Senate House, this was a historic occasion, for it marked the first approval of a new foundation for men in Cambridge since Selwyn College was admitted in 1882, and it means that the Trustees can now seek a Royal Charter and that Churchill may proceed in due course to achieve full status as a College of the University on equal terms with the older foundations. In its development to this stage of formal approval, the project has, naturally enough, met with some criticism in the University; but this has been less serious and less widespread than it has at times appeared to be from statements in the Press. The main lines of criticism have been on matters of procedure, on the clearly stated intention to have a numerical ratio of seven to three in favour of science and engineering in the student body, and on the vexed question of the desirable size of the University of Cambridge as a whole. Of the two latter, it has been pointed out, not unreasonably, by supporters of the project, that the growing importance of science and the current movement towards it in universities and more especially in our schools will, in any event, lead in the near future to a general bias in entries not unlike that proposed for Churchill and that since, under present conditions, pressure on entry to the University is so heavy, it is surely wiser to found a new college than to allow the system to be further weakened by a creeping inflation of existing foundations. It is significant that the grace approving Churchill College was accepted unopposed in the Senate House.

It is now little more than seven months since the Trustees launched their appeal, and the fact that more than £2,832,000 has already been subscribed, mainly by British industry, is a remarkable tribute both to the imaginative concept of a Churchill College and to Lord Knollys and his colleagues on the Appeal Committee. True, this sum still falls short of the original target by more than £650,000; but the Trustees hope that at least this sum may be obtained by their further efforts combined with those of the associated Churchill Foundation which, under the leadership of Mr. Carl Gilbert, chairman of the Gillette Co., is working to the same end in the United States. Already, however, the funds available ensure a firm foundation for the new College, and a number of steps have been taken to speed its development.

Building sites within easy reach of the main University precinct in Cambridge are nowadays difficult to find, but the Trustees have been fortunate in being able to purchase from St. John's College a large open site to the west of the river within 1½ miles of the city centre in an area close to that proposed for the new buildings for New Hall and Fitzwilliam House, to the Observatories and to the new University development area on the Madingley Road site. Bounded on the north and east by Storey's Way, on the south by Madingley Road and on the west by the grounds of the Observatories, the site extends to some 41 acres and will accommodate not only the College buildings but also its playing fields. Building a new College in Cambridge is an exciting project, and many different architectural approaches are possible. For this reason, if for no other, it was probably a wise decision to invite twenty firms of architects to enter a limited competition. The competition will be judged by a panel consisting of two Trustees and three distinguished architects, and it is hoped that the winning design will be translated into action within the year. The Trustees have given no indication of their own views on building; but it is hoped that the opportunity will be taken to build in the modern idiom, and to provide in the College buildings a permanent record of the best in mid-twentieth century architecture.

It has, of course, been clear that early appointment of the first Master of Churchill College would be necessary, since the beginning of a building programme will quickly bring in its train problems which require the Master's decision. Moreover, in preparing for the admission of students and in the initial stages of its work, a Master of outstanding quality is necessary if the College is to build itself into the Cambridge pattern and, at the same time, introduce new ideas and methods, and avoid the pitfalls which constructive criticism in the University has pointed out. The choice of Sir John Cockcroft as first Master will be widely acclaimed. Not only is he a brilliant physicist with a strong sympathy for engineering, but also his work in developing the Atomic Energy Research Establishment at Harwell has shown him to be an outstanding scientific administrator. More than this, he has long shown a strong interest in scientific education, and he is widely known as a man with a deep affection and respect for Cambridge and its traditions. With Sir John in charge, Churchill College should be off to a good start.

The announcement that future appointments to the Mastership will be made by the Crown has given rise to some discussion. Crown-appointed masters exist in two colleges only—Trinity College, Cambridge, and Christchurch, Oxford—the common practice elsewhere being for masters to be elected by the Fellows themselves. Each system has its merits and demerits, but the evidence from Trinity and Christchurch suggests that appointment by the Crown can be very successful, and it provides at least some guard against the 'safe' but undistinguished elections made at times under the other system.

It is no easy task to build such a complex organism as a Cambridge College from scratch, particularly when it is sought to blend science and the arts in a predetermined ratio. Recruitment of staff and selection of students both present their own problems, and a gradual building-up process will be necessary; but these difficulties are offset by the opportunity to break new ground educationally. In their original memorandum the Trustees laid particular stress on postgraduate training in science and engineering for both home and overseas students, and they emphasized the need to encourage men to return from industry for a period of study and research. The provision of laboratory facilities and courses for such purposes will be the task of the University departments of science and engineering, but, through its tutorial facilities and specialist Visiting Fellowships which it hopes to maintain, Churchill College can make a new and important contribution to the Cambridge scientific scene. Much has been said and written about the need for a closer welding of science and the arts in our system of university education. Churchill College has the opportunity to experiment in this field, too, and we may hope that under Sir John Cockcroft's guidance it will not be overlooked. For teachers we must have, and, if Churchill College can produce men to lead in teaching as well as in industry, then it will indeed fulfil the high hopes of its Trustees and of its many benefactors and well-wishers.

NEURO-MATHEMATICS

The Computer and the Brain

By Dr. John von Neumann. (Mrs. Hepsa Ely Silliman Memorial Lectures.) Pp. xiv+82. (New Haven, Conn.: Yale University Press; London: Oxford University Press, 1958.) 24*s*. net.

THIS book constitutes the last writing to come from this eminent mathematician, a short account of whose life and last illness leading to his tragically early death in 1957 is given in a preface to the book by Klara von Neumann. The manuscript, intended for the Silliman Lectures in 1956, was never finished.

The first half of the book summarizes the characteristics of man-made computers. It distinguishes between analog and digital machines and the degrees of precision attainable in each, between parallel and serial methods of computation, between plug-board and memory-stored control, between active (arithmetic) units and inactive (memory) units, and discusses access times, memory capacities and so on.

The second half of the book compares the natural nervous system with artificial computers. It appears that the natural 'computer element'—the neurone—has a rather slow reaction time (10^{-2} sec.) compared with modern artificial devices. Von Neumann further implies that the method of transmitting information by digital pulse trains, interpreted in terms of pulse-time density to give digital-type logical information but analog-type quantitative information, will reduce the effective 'computing speed' by a factor of ten for each effective decimal place of accuracy. The loss of an occasional digit, however, would not be disastrous in the method of operation described.

On the other hand, he suggests that the effective memory capacity of the nervous system must be, and could plausibly be, of order 10^{20} decimal digits, in order to record a life-time of experienced sensations.

The overall picture is that the brain is, compared with modern machines, a very reliable and compact computer, with a low speed and a low order of accuracy in individual calculations, but an enormous (inactive) memory capacity, a large (active) arithmetico-logical assembly (highly parallel operation), and great economy in power requirements.

Von Neumann then argues as follows: since the brain has to control such a highly complex organization as the human body, it must carry out long (arithmetically deep) calculations. The brain cannot work to 10 or 12 decimal accuracy, which we know to be necessary in artificial computers, to retain two or three figure final accuracy. Hence, he argues that some different and unknown form of mathematics must be employed in the brain to produce its satisfactory results, and that conventional mathematics and brain-language stand in the same relation as an interpretive code to basic machine language, or vice versa.

In this connexion there are two relevant points, the first being hinted at by von Neumann himself, and the second, perhaps, being a point which he would have included in the book if he had been given time. First, the loss of accuracy at each stage of a long calculation may, perhaps, be eliminated by carrying out a large number of independent calculations at each stage, and evaluating the results statistically. By reason of its large 'active' assembly the brain would be well equipped to do this.

The second point is this: when planning a computation one has the choice between calculating everything *ab initio* (suitable for fast, small-memory machines) or using 'tabulated' results of earlier auxiliary calculations (suitable for slow, large-memory machines like the brain). The reviewer therefore suggests that the brain never does any arithmetically deep calculations—it merely makes minor interpolations, variations and extensions to a vast stock of 'tabulated solutions' which it has been accumulating (on a basis of trial and error and statistical selection) in its memory throughout the course of its development from a single cell. Really basic problems, like digestion of food and circulation of the blood, have perhaps been tabulated pre-natally for reference in this way. Slightly less basic problems, like learning to walk, have not been solved prior to birth, and it takes the infant's brain-computer many months to solve this problem. Even the adult's brain-computer may take a week to solve the rather simple problem of riding a bicycle. When obtained, this solution, or rather 'grid of experimental results', is stored in the memory for future use by simple interpolation.

By bringing together two diverse bodies of knowledge—computer technology and neurology—the author wrote a most stimulating book, containing material for much further thought.

A. H. Armstrong

SPECTRAL CASEWORK

Four Modern Ghosts

By Eric J. Dingwall and Trevor H. Hall. Pp. iii+8 plates. (London: Gerald Duckworth and Co., Ltd., 1958.) 15*s*. net.

THE first case concerns the repeated popping out of a book from a library shelf. In the authors' considered opinions the presence of a black nylon thread may have escaped the attention of the witnesses of the phenomenon. They then revive the late Harry Price's sensational story of how he visited an unnamed house and witnessed the most extraordinary séance ever vouchsafed a sceptical investigator. The living, breathing, talking figure of the little girl Rosalie materialized within a sealed room. The medium disappeared soon after, and the persons present have never been traced. The authors conclude, as have many others before them, that Harry Price, whose romancing propensities they exposed in a previous book, must have invented the whole episode. The third case is a typical poltergeist, with unexplained knockings and movements of objects at night, especially when two youths are about, and one member of the family said to have been caught by newspaper reporters in the act of throwing a book. The authors preserve "an attitude of suspended judgement". Finally they deal with bumpings, tremblings and noises in a house in Ousedale, and here they succeed in clearing the housemaid suspected of responsibility and placing the blame on subsidence due to subterranean water.

To quote the words the authors use of Harry Price, they may not have "advanced our knowledge of the supernatural in any way whatsoever", but they give a good display of professional zeal. The question looms large in their discussions whether their former collaborator, Mrs. Goldney, was once taken in by Harry Price. In reference to the Society for Psychical Research, they comment mildly in several places that, until recently, no discussion of the seismic theory of haunting noises has appeared in the Society's publications, but they quote an ancient letter to *The Times* describing the Society's methods of investigation as fit to "provide contempt in Bedlam itself". In an ingenious juxtaposition of sentences they say that "Mrs. Goldney became Organizing Secretary of the Society" but fail to mention that Dr. Dingwall himself was once its research officer.

The authors advance the theory that Harry Price, from lack of inventiveness, placed his imaginary séance with Rosalie in Brockley where years before he had attended some fake séances. They say they have discovered "correspondence which proved positively that Price has revealed that the séance was at Brockley", but though they quote extensively from all sorts of correspondence they give absolutely no details about this discovery. One suspects this lapse must have lost them several points of 'investigationmanship'.

RESEARCH ON FOOD

Advances in Food Research

Vol. 8. Edited by E. M. Mrak and G. F. Stewart. Pp. xii+437. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1958.) 12 dollars.

Processed Plant Protein Foodstuffs

Edited by Aaron M. Altschul. Pp. xv+955. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1958.) 26 dollars.

The Microbiology of Fish and Meat Curing Brines

Proceedings of the Second International Symposium on Food Microbiology held at Cambridge (United Kingdom) in April, 1957. Edited by Dr. B. P. Eddy. Pp. vi+336. (London: H.M. Stationery Office, 1958. Published for D.S.I.R.) 45*s*. net.

Bibliography of Food

A Select International Bibliography of Nutrition, Food and Beverage Technology and Distribution, 1936–56. By E. Alan Baker and D. J. Foskett. Pp. xii+331. (London: Butterworths Scientific Publications; New York: Academic Press, Inc., 1958.) 63*s*.; 11 dollars.

Flavor Research and Food Acceptance

A Survey of the Scope of Flavor and Associated Research compiled from papers presented in a Series of Symposia given in 1956–1957. Pp. vi+391. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1958.) 10 dollars.

THE ever-increasing number of published papers on all aspects of science makes it more and more difficult for scientific workers to keep abreast of what is being discovered. The streets of London are to-day filled with complex machines designed to enable a man to move rapidly and comfortably from place to place, yet the net speed of movement is slower now than it was in the days of the hansom cab. In just the same way, the congestion of publications makes it as difficult to-day to be well learned in one's subject as it was in the earlier centuries of science.

There are several ways of dealing with the situation. To read all the published material is impossible; to digest the great fortnightly editions of *Chemical Abstracts* takes more time and determination than many of us can command; even to master the close-woven pages of the annual reviews is sometimes a heavy task. The editors of "Advances in Food Research" have chosen the more scholarly approach. They have selected six authors, three from the United States, two from England and one from Holland, and asked each to write a critical review. The result is an excellent book. G. W. Scott Blair discusses rheology in food research with all the mathematical erudition which we would expect for an article in such a volume, but also with philosophical urbanity which is equally to be welcomed. P. A. Raelofsen reviews the out-of-the-way corner of the fermentation industries concerned with the processing of cacao beans. A. C. Hulme deals with the biochemistry of dying organisms, namely, apples and pears. F. A. Lee and M. Milner contribute excellent articles, the first on the blanching of vegetables and the second on new methods to detect and eliminate insect-infested grain. The total impact of the book is to emphasize the axiom that the line between pure and applied science is a blurred one when good scientists write.

"Processsed Plant Protein Foodstuffs" is also an excellent compilation. With great thoroughness and in 955 pages the international team of thirty-eight authors has amassed a reference book of documented information on oil-seed meals of every sort as well as on by-products of milling, fermentation and much else. To leaven the lump, R. F. A. Dean has contributed from the Medical Research Council unit in Kampala, Uganda, an excellent and balanced review on the use of these vegetable proteins in human nutrition.

"The Microbiology of Fish and Meat Curing Brines" consists of thirty-eight papers, mostly quite short. They will be of interest to the people who attended the congress at which they were originally read. Scientists whose interests in biology are more general will be prepared to wait until the observations, facts, comments and doubts reported here are fitted into a more complete picture.

The "Bibliography of Food" is a most systematic affair, ranging widely from lists of grocers' journals to Sumner and Myrback's monograph on enzymes—unexpectedly entered under "nutrition: vitamins". The compilation of a bibliography, however, is a treacherous business even if it is a 'select' one. But though the authors do list Plimmer's historical tables of food composition and omit to mention the workaday ones of McCance and Widdowson, all in all they deserve our thanks for their efforts to codify the sources of twenty years of information on food.

"Flavor Research and Food Acceptance", fathered by no live editor but by an institution, Arthur D. Little Inc., is very good in parts, notably the excellent sections by L. M. Beidler and C. Pfaffmann on the physiology and psychology of taste, respectively. Other chapters are on a different level. For example, it appears that an agreeable aroma is important for the sale of petrol as well as soup. The book is a marriage of commerce and science, and the marriage is not an altogether happy one. MAGNUS PYKE

INFECTIOUS DISEASES

Die Infektionskrankheiten des Menschen und ihre Erreger

Herausgegeben von Prof. Dr. A. Grumbach und Prof. Dr. Kikuth. Band 1: Pp. xl+1–840. Band 2: Pp. iv+841–1702. (Stuttgart: Georg Thieme Verlag, 1958.) 198 D.M. (zwei banden).

THIS work is the product of the experience of Dr. Grumbach of the Institute of Hygiene, Zurich, and of Dr. Kikuth, the well-known pioneer in malaria and chemotherapy, assisted by a number of German, Swiss and other specialists. It is written from a novel point of view—to facilitate the understanding of the laboratory and scientific sides of infective disease by the clinician, and of the medical side by the biologist. It is not a laboratory manual in that details of technical procedures are largely omitted, and it is entirely bereft of illustrations, but throughout the book the clinical and therapeutic descriptions are intimately related to etiology; another title might have been "Clinical Microbiology".

The first part is occupied by a description of the general principles of the subject as a whole (such as virulence, epidemiology and immunity) and of the specific groups (bacteria, rickettsia, viruses, fungi, protozoa and helminths), followed by useful chapters on chemotherapy (by Klein), disinfection (by Roemer) and disinfestation (by Weyer). The second part forms three-quarters of the two volumes and is devoted to the individual infections. Each is considered under the following headings: signs and symptoms, morbid anatomy, infective agent, pathogenesis, epidemiology, diagnosis, treatment, prophylaxis and control. This uniform classification makes it easy for reference, while an up-to-date bibliography, at the end of each section, indicates original sources, methods, etc. The greatest attention is paid to the bacterial and virus diseases (about a thousand pages); the parasitic infections are considered in much less detail, and organisms of minor importance are omitted (such as *Sarcocystis*, *Pneumocystis*, *Trypanosoma rangeli*, *Isospora belli*, *Iodamoeba butschlii*). The book is clearly written and well produced, and is specially recommended to workers in temperate zones; it will undoubtedly form a standard text-book on the subject of microbiology. P. C. C. GARNHAM

CHEMICALS AND INSECTS

Methods of Testing Chemicals on Insects

Vol. 1. Edited by Harold H. Shepard. Pp. iv+356. (Minneapolis, Minn.: Burgess Publishing Company, 1958.) 40*s*.

THIS is the first volume of a work of which another one, or possibly two, further parts are projected. The preface says, "This manual is intended to describe methods used in studying any phase of the action of chemicals on insects", and this first volume is devoted to the more fundamental aspects of the subject and to general techniques. More specialized subjects, such as testing chemicals for wood impregnation, soil treatment, as repellents and acaricides, are reserved for the second volume.

The sixteen authors, thirteen American and three British, are mostly well known. Together they contribute fourteen chapters which may be given the following condensed titles: (1) cuticle surface; (2) cuticle penetration; (3) respiration; (4) electrophysiology; (5) circulation; (6) radioactive tracers; (7) resistance; (8) topical application and injection; (9) feeding; (10) dipping; (11) spraying surfaces; (12) dusting; (13) fumigation; (14) synergism. It will be noted that methods for testing space sprays, mosquito larvicides and systemic insecticides are not included.

The chapters vary greatly in length (from seven to one hundred and five pages) and in the detail with which the subjects are treated. It appears from the preface that the editor has had some difficulty in collecting the contributions. Perhaps this is why so little attempt seems to have been made to impose on the authors a greater uniformity of presentation. For example, in dealing with the actual methods the author may simply refer to the literature, give an outline description and refer to the literature for details, or give a full description down to the last particular. Furthermore, authors are clearly uncertain how much attention to give to the vital subject of standardizing and handling the test insects and to discussing the relationship between the insects and the insecticide under the test conditions. Some scarcely mention these subjects while others treat them at great length and refer to much literature which more properly belongs to other chapters.

The work invites comparison with "Techniques for Testing Insecticides" by J. R. Busvine already reviewed in *Nature* (182, 486; 1958). Criticisms may be made of Dr. Busvine's book, especially of some of the explanations and interpretations he gives of the experimental methods he describes, but it is a better balanced work and more logically planned. On the other hand, perhaps none of the chapters is as clear, accurate and complete as the best in the present book —for example, Chapters 8 and 11. The type is bold and the book is pleasantly produced. The index is extremely brief.

There is no doubt that many people engaged in testing insecticides will find this book useful and convenient as a reference work. But there is equally no doubt that the general planning of the book and the contents of some of the chapters could have been considerably better. The ideal reference work on this subject has still to be written. W. A. L. DAVID

In a practical determination of the errors of a system to which such an input is applied, computer techniques are very desirable. The design of analogue computers for such simulation studies is considered. The errors in autocorrelation measurements are studied, first with particular reference to signals that are random in the video range and later for signals which have first been demodulated from radio frequencies either by a linear or a square law detector.

The topic is exceedingly thoroughly treated by the author, and, although essentially of a mathematical nature, he has not failed to keep the essential engineering nature of the problem before him. R. A. KING

NOISE THEORY

Principles and Applications of Random Noise Theory

By Dr. Julius S. Bendat. Pp. xxi+431. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1958.) 88*s*. net.

NOW that electrical science has within its grasp a wide variety of instruments of ever-increasing sensitivity, it is imperative that the design of such instruments should be such that the information obtained from them should be as little as possible dependent on random external influences. This problem occurs again in the general field of communication where it is desired to identify some desired signal in the presence of some completely masking spurious signals. The available knowledge in these fields has been collated and amplified in this book by Dr. J. S. Bendat.

It is essentially a book for the advanced student in the field of noise investigations, although the introductory chapters do give a very clear review of the basic mathematical concepts on which all the theory is developed. Correlation functions are here defined and the special significance to the engineer of the exponential-cosine correlation function is very wisely stressed. Other important concepts included in this introductory section are power spectra and their relationship with correlation functions, and also sampling theorems.

The book develops with a fairly detailed study of probability theory; its applications to a number of random variable situations follow, well illustrated by a few simple engineering problems. As a final consideration, a situation outside that where the normal distribution holds is considered, namely, the case of the distribution of a noise envelope.

With this background, the ultimate object of the book becomes apparent in the next chapter. This is devoted to an investigation of the design of a network which will produce with any specified error some stated function of an input signal which has been degenerated with noise. This analysis is extremely general, being an extension of the pioneer work of Wiener to less restricted situations. The further problem of separating a desired signal from two received signals, both of which are degenerated by independent random signals, is also considered and illustrated by a deep problem on control.

The author now illustrates the wide applicability of the exponential-cosine autocorrelation function by a consideration of a number of varied practical systems in which it is applicable.

AVAILABLE ENERGY IN THERMODYNAMICS

La Thermodynamique et le Théorème de l'Énergie Utilisable

Par R. Marchal. Pp. xxx+208+7 planches. (Paris: Dunod, 1956.) 1580 francs.

IT would appear that the author of this book felt a mission to bring to the notice of engineers the concepts and theorems of available energy, which are too frequently ignored in engineering text-books. The chapter in which this subject is treated well repays close study, although it would be possible to improve on some of the methods of presentation. Unfortunately, the preceding five chapters, on the first and second laws and the properties of perfect gases, cannot be recommended as a good introduction to the later chapter.

In the preface the author sets himself against a course which, in attempting to be a monument of deductive logic, loses contact with reality, but he goes to the other extreme in failing too often to define his terms clearly. Failure to define 'heat' results in surprising confusion of thought in several places. In the presentation of the first law, system analysis is perfunctory and no mention is made of control surface analysis as such; this may account for a confusion between thermodynamic cycles undergone by systems and mechanical cycles of operation of engines. These confusions place severe obstacles in the way of students hoping to understand the later and more worth-while chapter on available energy.

Many will not agree with the author, a professor in the École Nationale Supérieure de l'Aéronautique, that the ease of their mathematical treatment justifies the early introduction of perfect gases, which receive undue prominence in the text. Nevertheless, their use permits the presentation of two very interesting charts showing the available energy (availability) in non-flow and steady-flow as a function of the temperature and pressure ratios of system and environment. The author does well to point out in a footnote that the chemist's uses of the functions F and G result as special cases from the engineer's more general study of availability functions, although the book does not deal with the analysis of combustion problems or chemical reactions. The last chapter, on the representation of fluid properties, contains a useful but brief treatment of characteristic functions.

While a study of the chapter on available energy may prove rewarding, the book cannot be recommended as a standard text on thermodynamics.

R. W. HAYWOOD

Social Class and Mental Illness

A Community Study. By Prof. August B. Hollingshead and Prof. Fredrick C. Redlich. Pp. xii+442. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1958.) 60*s*. net.

THIS book is the record of work done jointly between Prof. A. B. Hollingshead, who occupies the chair of sociology at Yale University, and Prof. F. C. Redlich, who is professor of psychiatry at Yale University School of Medicine.

As might be expected, the research is meticulous and explores a section of psychiatry which has been singularly neglected. Commencing with a history of the New Haven community and revealing interesting details of the earliest members, they then deal with the history of psychiatry there. This brings the book up to the present time and an examination of the problems they have set out to investigate. These are the different classes of society and the nature of the mental and nervous illnesses which are to be found associated with them, how the members of the different classes become patients and how their relatives react to the necessity for psychiatric treatment.

Strangely enough they find that the members of the wealthiest classes tend to be dissatisfied with themselves when they are ill, the middle classes have anxiety symptoms, and the lower class neurotics develop aches and pains. The very lowest class develops behaviour disorders rather than neuroses. Psychotics appear in greater numbers in the lower classes and this seems to be caused not by a downward drift in society but by something else, probably stress and strain, in the environment.

This book is well worth the study of psychiatrists interested in social factors, and it is to be hoped that future work along the same sort of lines will be undertaken in Great Britain. CLIFFORD ALLEN

Tupu-Tupu-Tupu

By Peter Krott. Translated from the German by Edward Fitzgerald. Pp. 232+25 plates. (London: Hutchinson and Co. (Publishers), Ltd., 1958.) 21*s*. net.

THERE seems to be no limit to the extent man will go in his quest for new knowledge. During the past thirty years the unparalleled discoveries in natural science have been accompanied by investigations in natural history which are themselves tribute to man's curiosity, resource, persistence, patience and courage. Birds and the not-too-dangerous animals, for example, have been observed with such diligence and devotion that many new truths about animal behaviour have been revealed. To join the swelling ranks of this fine army of observers comes Peter Krott, an Austrian who made his home in northern Finland and Sweden and who became captivated by the study of that very dangerous animal, the wolverine, or glutton.

Despite incredible difficulties and much stupid and hostile opposition from so-called 'sportsmen', Krott secured the support of the Swedish Forestry Department to carry out systematic studies of an animal of which little was known other than that in northern mythology it was reputed to be the incarnation of the Devil. Krott showed that the mystery surrounding the wolverine was largely because it lived a much more secluded life than other beasts of prey, was avoided even by powerful animals like the bear and northern lynx because of its fighting abilities, was capable of considerable domestication if caught young, exhibited ferocious territorial behaviour and would not tolerate other wolverines of the same sex in the territory. The book is well written and the translation from the German owes much to Edward Fitzgerald; it contains some remarkable photographs.

Basic Physics

By Dr. A. R. Meetham. Pp. xi+144. (London and New York: Pergamon Press, 1957.) 21*s*. net.

DR. A. R. MEETHAM deserves praise for what is indeed a bold departure from the standard method of presentation of physics at the Advanced Level of the General Certificate of Education. He admits, in the preface to his book, that intending university students will need something more advanced, but for the average fifth- and sixth-form pupils many of whom have no intention of making their living by physics and for whom the Advanced Level is the end of their study of the subject, the large number of historical facts, methods, reasons and proofs which they have to memorize, Dr. Meetham maintains, only tend to obscure the basic physical principles. Hence "Basic Physics" is shorn of all these details, representing Advanced Level physics, with everything human, historical and experimental eliminated. Mathematics is not excluded, but is used mainly only to express symbolically the relationships between quantities, and mathematical proofs are deliberately avoided. A glance at the book is sufficient to see that Dr. Meetham knows what he is doing and why, and that his subject-matter is good, sound physics, clearly expressed and well arranged in a connected pattern. However, in many places it becomes so bare that it consists merely of a list of definitions and formulæ. It is an excellent book for sixth-form revision and perhaps also for university scholarship candidates. It stimulates thought by its provocative attitude of expression and approach, and its frank re-statement of the fundamental processes of physics, but it is not an Advanced Level text-book of physics. S. WEINTROUB

Communications and Electronics Buyers' Guide, Who's Who and Reference Book, 1958–9 Edition

Edited by C. C. Gee, with the assistance of D. W. Dwyer. Pp. 360+156. (London: Heywood and Co., Ltd., 1958.) 105*s*.

THIS is a well-produced and well-edited book, large in bulk and price, but full of information likely to be of value to all engaged in electronic work. It covers the whole of electronics, and by including allied industries it is enabled to cover acoustics, materials, etc. The bias is strongly towards what it calls "capital-equipment electronics", and the consumer sector of the industry is only briefly covered since there are other sources of data on this.

The Buyers' Guide Section has several alphabetical indexes, and the first of these—the classified index of products—is probably the most important. Under each product are given the names of the firms manufacturing it. The Who's Who Section may be of some value, but there are better works of this kind. The Reference Section is certainly valuable; the product surveys are probably the most useful part of the whole book. In them, all known products under a heading are tabulated, together with their salient performance characteristics. The book vividly portrays the amazing recent growth of a major industry.

D. G. TUCKER

ORIGIN OF THE RADIATION NEAR THE EARTH DISCOVERED BY MEANS OF SATELLITES

By Prof. T. GOLD
Harvard College Observatory, Cambridge, Mass.

INFORMATION has been obtained, both by Van Allen and his group in the United States[1] and by Russian workers with satellites[2], showing the presence of an intense flux of penetrating particles over most of or all regions of the Earth at heights in excess of 600 km. The most detailed information to date comes from Van Allen and his group, and was obtained with the aid of the *Explorer* 4. Neither the spectrum nor the identity of the particles has yet been established; but it is clear that one is here concerned with a very major phenomenon, either in the outer zones of the Earth's magnetic field or indeed in the whole of our region of the solar system. The observations indicate an increase in the flux with height, and the *Explorer* data that go up to a height of 2,200 km. still showed the high rate of increase there. The energy-range of the charged particles concerned seems to extend from perhaps several tens of keV. to several tens of MeV. Intensities of the order of a few hundred particles per steradian per cm.^{2} per sec. capable of penetrating the shielding of 2·5 gm. per cm.^{2} have been recorded. At the low-energy end of the range there appear to be fluxes of the order of 10^6 or 10^7 particles per cm.^{2} per sec. per steradian.

In addition to the satellite observations, there exist the auroral observations indicating high fluxes and a very steep energy spectrum in an actual aurora[3,4]. As many as 10^8 electrons per cm.^{2} per sec. per steradian with energies of the order of a few tens of keV. are thought to exist in actual auroral formations, and to be responsible for much of the light emitted there.

For any of the energies concerned, and for either protons or electrons, it would be true that the Larmor radii in the Earth's magnetic field are very small compared with the radius of the Earth; and it is this fact that allows one to discuss all this flux under one heading and without a more complete knowledge of identity or spectrum. For example, a 10-MeV. proton at a height of 3,000 km. above the equator would have a radius of gyration of approximately 3 km.

It is very tempting to think of the auroral flux and of that observed at lower latitudes and greater heights by the *Explorer* as being part of the same phenomenon. On that basis one can give a lower limit to the rate at which energy must be fed into the whole region from an estimate of the mean auroral brightness and the efficiency of light production. Cosmic-ray secondaries have been discussed as a possible source for this particle flux[5], and although neutrons scattered from the atmosphere and decaying there would provide a means of supplying such a flux, the total energy obtainable falls short by a factor of 10,000 for supplying the mean auroral light. The auroral flux can thus not be thought of as being a flux of stored particles in captured orbits in the Earth's field produced by cosmic rays and diverted through the magnetic disturbance into the auroral atmospheric zones. Some other and enormously more energetic source of supply for this flux must be found.

To clarify the requirement for the injection mechanism, let us consider first the range of orbits possessed by these particles. A charged particle in this energy-range liberated at some height above the atmosphere on the equator would in general spiral around the lines of force and thus proceed to a higher latitude and lower height (Fig 1). It would thus travel into a converging magnetic field and, as is well known, the pitch angle of the spiral orbit (that is, the angle between the trajectory and the magnetic field) would become larger and reach 90° at a particular point. In effect, the particles would be reflected and travel with the guiding centre closely following the line of force to the corresponding point in the other hemisphere. The position of the reflexion point, or the field-strength that occurs there, is defined by the field-strength and pitch angle of a particle at any other point of its trajectory through the good approximation that the magnetic moment of the orbiting particle must remain constant. The reflexion point is then given by the place where the field-strength reaches the value $B = B_0/\sin^2 \psi_0$, where B_0 is the field-strength at some other point on the trajectory and ψ_0 is the pitch-angle of this trajectory there.

The observed flux must thus be due to particles that oscillate quickly in spiralling orbits between the two hemispheres with a distribution in latitude related to the distribution of pitch angles.

This rapid oscillation, with periods of the order of a fraction of a second to seconds, is, however, not the only motion taking place. For the dipole-like field, the field-strength has a gradient not only along the lines of force but also across them. A slow drift motion of spiralling particles then occurs in a direction

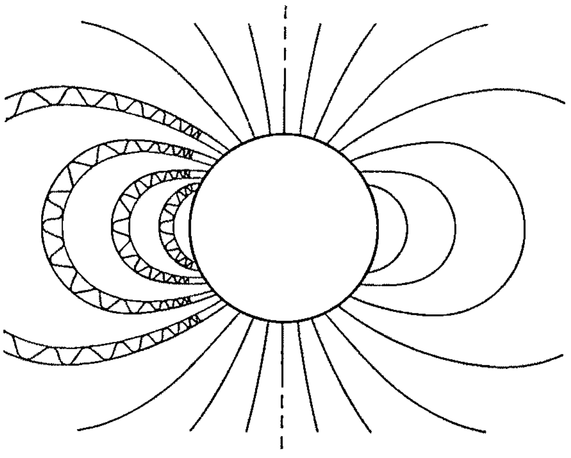

Fig. 1. Lines of the Earth's field and a schematic representation of some spiral orbits of charged particles showing the oscillation between the two hemispheres, and the reflexion in the converging fields

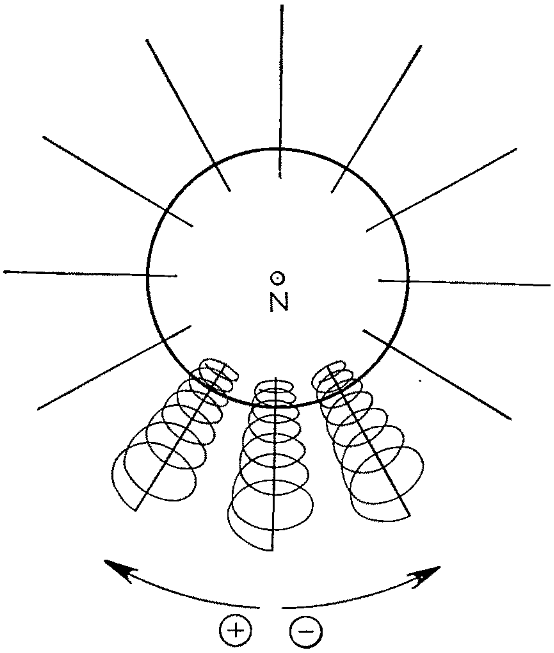

Fig. 2. Captive particle orbits, schematically, as seen from above the North Pole. Electrons will drift slowly eastwards, positive ions westwards

normal to the field and normal to its gradient, and for a perfect dipole field this would be a motion in longitude. This migration would take the particles once around the Earth in a time that depends upon the particle energy and the height of the orbit, but would generally be between a few minutes and a few hours. For a perfect dipole field and in the absence of any scattering by gas molecules, this would be the complete description of the types of motion that can occur.

The actual field of the Earth is very substantially different from a dipole field, as, for example, there are large regions on the surface where the field-strength differs by as much as 20 per cent from that which would result from the otherwise best-fitting dipole. The non-dipole parts of the field now provide a further type of drift motion of the particles, and, as there are gradients of the field in longitude, there will be drift motions in height. The individual orbits then become very complicated, and will in effect represent a diffusion of the flux in height.

In addition to the non-dipole, permanent features of the field, there are the magnetic variations impressed from outside. These also will make for complicated orbits that effectively diffuse the flux. As the non-dipole components of internal origin diminish faster with height than the dipole field, while the proportion of the field-strength due to the externally impressed variations must increase with height, the external effects will dominate above a certain level. Also the type of orbit changes that can be effected with a time-dependent field may be significantly different from the drift motion in a steady field.

There are then the four different modes of motion of particles, each with a different time-scale : (*a*) the gyration in the field ; (*b*) the quick north–south oscillation along lines of force ; (*c*) the drift in longitude ; (*d*) the drift and diffusion in height. Of these motions, it is only the last the time-scale of which cannot easily be calculated ; but it is certain that this motion is much slower than the drift in longitude. As molecular collisions are rare, leading to time-scales of many years[5] for the flux stored in a perfect dipole field, it is also most likely that the drift in height is the main agency for the removal of particles from a given zone. An upward drift would result in a loss of particles from the vicinity of the Earth, while a downward drift will result in their dissipation in the atmosphere.

For all but the highest particle energies, the magnetic moment of the orbiting charge must remain constant throughout the motion. The migration in the field will therefore be limited for any particle to the region in which the field-strength is less than $B_0/\sin^2 \psi_0$, where B_0 and ψ_0 are the field-strength and pitch-angle, respectively, at some point along the orbit. Of a particle flux injected at a greater height only a certain proportion, namely, that injected with steep enough pitch-angles, will be able to reach the lower level. The equatorial regions are therefore accessible to a larger proportion of the particles than the higher latitudes where the field-strength at a given height is greater.

The migration of particles by molecular collisions is an insignificant process, as many more collisions would be required to cause a significant displacement than to dissipate the particle energy. But this does not mean that collisions are unimportant, for in a single collision the pitch angle of a particle may be changed from a flat to a steep one, and the region accessible to further migration will then be greatly increased.

For any flux with particle energies above some tens of MeV. the rule of the conservation of the magnetic moment would not apply accurately any longer, and the vertical migration would therefore not be subject to the same strict limitations.

With these properties of the flux in mind, let us now consider the consequences that would result from a supply of such particles initially isotropically at a point at, say, 5 Earth's radii above the equator. Of the isotropic flux, a small fraction would be travelling very nearly along the lines of force, and that fraction would be able to reach immediately to high latitudes and low heights. All the flux within a certain small angle to the lines of force would thus reach into the atmosphere and be dissipated there. The immediate effect would thus occur where the particular lines of force on to which the particles were supplied dip into the atmosphere, and an auroral luminescence lighting up these lines can be expected. The flux will thus suffer a change, in that the steepest-pitched particles are removed. Also a spread in longitude will set in through the action of the drift in the dipole field, and this spread will be fastest for the highest energy particles. Particles will thus be supplied around the entire belt of magnetic latitude, but will not dip quite so deep into the atmosphere. One would thus expect an auroral luminescence at a higher level, stretching out around the entire auroral bands.

For a perfect dipole field concentric with the Earth the drift motion in longitude would merely result in a steady weakening of the aurora along the belt in the direction of the drift (eastward for electrons), as the steeper pitched particles get removed. But in the actual case where the best-fitting dipole is significantly off centre, and where the non-dipole components are significant, this variation in longitude must be expected to be quite different. At some particular longitudes on the Earth where the field at a given height is weakest the reflexion points of particles will be lowest, and therefore a flux will penetrate into the atmosphere there that had escaped dissipation at other longitudes. Such places in the field ought, therefore, to show auroræ always following an injection of particles and an aurora at any other longitude. The detailed dependence upon longitude can also reveal the sign of the charges of the particles responsible, by the sense of the longitude drift motion that would give the observed effects. Thus a local minimum in the field ought to have the greater auroral activity generally to the west if electrons are responsible.

If the original supplied flux was isotropic, then only a small fraction, of the order of 1/1000, will have been in steep-pitched auroral orbits. All the remainder will drift around the Earth and will gradually be distributed in height through the action of the inhomogeneities and the variations of the field. This distribution in height will happen comparatively quickly down to levels where the field-strength is such that no change of magnetic moment of a particle is required to reach there. Thus the steepest-pitched particles of the original flux that are left over will be the ones to migrate to the lowest levels, and they will be able to reach such field-strengths as they reached above the auroral zones without striking the atmosphere.

Without a detailed understanding of the complicated orbits leading to the diffusion in the field, the following general statements can still be made. First, the flux will get weaker as one goes away from the place where it was supplied. Secondly, time variations in the supply of particles to the system will be smoothed out with time constants given by the diffusion time that occurs between the point of supply and the point observed. Such diffusion times may well be a matter of weeks or months for the inner zones that have so far been observed. The flux that has suffered the longest migration in the field can be expected to show the least time variations and to show a tendency for the lines of constant intensity to follow not the field lines but the lines of constant field-strength. A shallow maximum of a rather steady flux above the equator is therefore to be expected, and it seems to be found in Van Allen's data. The lower regions of this zone have to be identified with the auroral belts, while above the equator the zone would be at a height of 4–6 Earth's radii. This zone has often been suggested as the supply route for auroral particles. In the present discussion I essentially add only the consideration of the fate of all those particles, several hundred or a thousand times as many for the case of isotropic injection, that travel in insufficiently steep-pitched orbits to reach down to the atmosphere and cause an aurora before being reflected in the converging field.

If observations of the particle flux are extended to greater heights above the equator one would therefore expect a continuation of the increase with height up to perhaps 5 radii, with a marked increase in variability and dependence upon the magnetic storm phenomena. The amplitude of the variations will, however, remain much smaller than those of the auroral flux, for even there the majority of particles will be in stored orbits that do not dip into the atmosphere. Beyond this height the flux will depend on the method of supply from the Sun, known to be highly variable.

If the phenomenon is thus interpreted, then the process of supply is intimately related to the magnetic-storm effects. It is thought that solar outbursts propel gas masses to velocities of the order of 1,000 km./sec., and that a magnetic storm phenomenon results when such gas masses strike the magnetic field of the Earth. On the scale of the phenomenon and with the degree of ionization involved, there is no doubt that the conductivity is high enough to ensure that the magnetic configuration is the one determined by the flow that has taken place. Thus, if a cloud of material expands from the solar surface, then any lines of force that it originally possessed linking it to the solar surface must be drawn out and carried along into all the spaces reached by the cloud. Unless the initial field in the gas was zero, such a cloud will thus remain magnetically connected to the solar surface. In order to discuss what particle fluxes may be present in the cloud of energies higher than those merely corresponding to its bulk motion, one has to consider what fluxes may be available generally on the solar surface; for any such particles will be able to move freely in their spiral orbits along all the lines of force drawn out by the cloud, and they will continue to populate all the regions reached by the cloud.

It is known that great solar flare outbursts can produce an intense flux of cosmic-ray particles at energies reaching to more than 10 BeV. Similar types of phenomena, but on a much smaller scale, seem to occur very frequently on the solar surface, and perhaps even continuously. Thus a supply of particles accelerated to energies much smaller than 10 BeV., but very much above thermal speeds, may well be constantly available on the solar surface and therefore may always populate all the lines of force that have been dragged elsewhere by outbursts of gas. Any magnetic-storm cloud approaching the Earth may thus have a high particle flux in it.

The speed of travel of the cloud itself determines the magnetic configurations, because it contains the necessary momentum. The high-speed particles possessing a total momentum insufficient to make the major changes of the fields can only come here together with the bulk of the gas clouds, and there is then no conflict in the observation that particles of MeV. energies appear here after time delays corresponding to velocities of only a few hundred or a thousand kilometres per second (proton energies of the order of 1 keV.).

For a static configuration of the Earth's field, the captive particle orbits are, of course, in a region that cannot be reached by such particles coming from outside. Particles may, nevertheless, be placed there in the course of a disturbance of the field configuration, and the magnetic-storm phenomena known to be associated with auroræ need, therefore, to be discussed.

The magnetic observations on the ground during a magnetic storm indicate that the phenomenon is very variable in time and also in position. Two stations at the same latitude but separated in longitude by as little as 1,000 km. show markedly different fluctuations. The sources of disturbance up above must thus be thought of as being very patchy, and indeed the same conclusion results from the appearance of the auroræ. Such a small-scale patchiness cannot possibly be attributed to the cloud that has come here from the Sun, but must be a phenomenon set up in the vicinity of the Earth by an instability of the flow of the solar stream around the Earth's field. Thus, if at a distance of, say, 5 Earth's radii there was not in existence a smooth surface dividing the terrestrial from the solar field, but a surface containing many fine corrugations or tongues with the scale of these variations not greater than a few hundred km., then this pattern would account for both the scale and the magnitude of magnetic disturbances on the ground.

For the small-scale features of this pattern, it would no longer be true to say that the dissipation of electric currents responsible for the fields can be ignored, and indeed such dissipation times may well be of the order of half an hour, which is the speed of many of the fluctuation phenomena observed. In that case, fast particles spiralling around the lines of one field which is decaying can be transferred to the lines of force of the other field which is being established in that space. A penetrating tongue of solar field can thus shed its particles into the terrestrial field as dissipation occurs.

The transfer of fast particles from lines of force of the solar field to the terrestrial one may also occur in a manner not involving any dissipative changes of magnetic fields. Shock waves in magnetized conducting gases are thought to develop a shock front at least narrow enough to be comparable with the ion radius of gyration in the magnetic field at thermal speeds. Particles of much higher than thermal speeds will therefore traverse such waves. At the instant when it is a shock front that divides the solar from the terrestrial gas, the fast particles are moving in fields that change substantially in distances short compared with their radius of gyration, and they will therefore not remain effectively attached to lines of force but distribute themselves to both sides of the wave. It is therefore to be expected that fast particles will appear in the Earth's field in orbits into which they could not have been placed without the magnetohydrodynamic effects associated with magnetic storms.

Van Allen has reported recently[6] that an increase in the flux of fast particles, as counted in the *Explorer* satellites, has been observed following a magnetic storm. R. R. Brown has observed[7] an excess flux of what may be interpreted as secondary X-rays during magnetic disturbances at balloon altitudes and at latitudes well below the auroral zone. As this is most likely a secondary phenomenon of the Van Allen flux higher up, it also suggests the dependence upon magnetic disturbance.

Further experimentation should be able to clarify the situation considerably. It should be possible to show, for example, whether the time variations become indeed greater at greater heights and higher latitudes. Magnetometer observations should indicate whether at distances of the order of 5 Earth's radii the field structure is frequently patchy. If the present considerations are correct, radiation measurements at such heights should usually show a slow decrease with height above the injection region, while occasionally, during a magnetic storm, a substantial increase should occur there. Rockets flown to greater distances from the Earth should be able to signal the magnetic and radiation conditions when they are enveloped in a magnetic storm cloud.

GEOPHYSICAL EFFECTS ASSOCIATED WITH HIGH-ALTITUDE EXPLOSIONS

By Dr. P. J. KELLOGG, Prof. E. P. NEY and Prof. J. R. WINCKLER
University of Minnesota

THE purpose of this communication is to indicate some geophysical effects which one would expect to be associated with high-altitude explosions of nuclear weapons or high-altitude chemical explosions. In addition to outlining the effects which one would anticipate seeing concurrent with high-altitude explosions, we will attempt to discuss two experiments which seem to bear on these problems: one was the Johnston Island nuclear explosion which was observed in some detail, geophysically, from the Apia Magnetic Observatory, and the other experiment is the recently reported high-altitude grenade shot at Woomera, Australia, which also seemed to be accompanied by geophysical effects.

The discovery by Van Allen and his collaborators at Iowa of the intense radiation belt surrounding the Earth has made it clear that stable trapped orbits of particles in the magnetic field of the Earth do in fact occur. We propose to discuss here the effects which accompany the release of these trapped Van Allen particles, as well as effects expected to be associated with the injection of additional particles from a nuclear explosion. Since the geometry of the trapping field determines the sort of effects to be expected, we will first discuss very briefly this geometry as it relates to our problem. Following this, we will describe effects characteristic of a nuclear explosion at high altitude, and finally, those to be expected from a large chemical explosion, also carried out at high altitude.

It is now quite generally recognized that the tubes of magnetic force surrounding the Earth act as a natural mirror, in which charged particles undergo helical paths oscillating between the northern hemisphere and the conjugate point in the tube of force in the southern hemisphere. The trajectories of these particles are determined by the pitch angles with which the particles pass the equatorial plane, and a given particle is reflected at that point in the field at which the trajectory becomes perpendicular to the magnetic line of force. With a perfectly symmetrical field, and in the absence of gas in which energy would be lost, the particles would oscillate between the northern and southern hemispheres indefinitely. The presence of gas in which loss of energy can occur at the lower altitudes causes the particles to have a finite life-time in this motion between hemispheres. Because, for reasonable energies, the radius of curvature is small compared to the radius of the Earth, the particles oscillate back and forth almost along a given magnetic line of force. For example, for a 1-MeV. electron, the radius of curvature would be approximately one-tenth of a mile near the surface of the Earth. Because the magnetic field is stronger at small radii than at large, in addition to the oscillating motion from northern to southern hemisphere, the orbits of the particles precess at right angles to a radius vector and constitute a ring current because of this precession. For example, for a tube of force at the equator near the Earth's surface, the precession of the orbit around the Earth would occur in approximately one hour. Although the exact number of particles present in the trapped radiation is not at present known, one can set an upper limit to the total energy of particles because of the known fact that the external portion of the Earth's magnetic field constitutes less than 1 per cent of the field measured at the surface. This upper limit of the energy of trapped particles in the Van Allen radiation is approximately 10^{27} MeV., or about 1,000 moles of trapped 1-MeV. particles. This limit does not depend on whether the particles are positive or negative, since negative particles precess to the east and positive to the west, and both constitute an effective ring current producing a magnetic field in the same direction at the surface of the Earth.

Finally, because of the inhomogeneities in the field, and because of the diamagnetism of the plasma gas, particles injected at a given point will tend to be distributed radially in a manner which is not easy to calculate. It is believed that this trapped radiation is of natural origin. The sources of replenishing it must be: (1) streams of solar gas; (2) neutron albedo from cosmic rays; (3) debris from high-altitude atomic explosions. All three of these sources must certainly contribute to the radiation, but it is not clear as yet which source is most important throughout the various ranges of energy involved.

The geometry of the tubes of force is such that the release of trapped radiation from the radiation belt would, qualitatively at least, give a very nice description of the auroral phenomena. Because of this, it seems to us to be quite crucial to test the hypothesis that Van Allen radiation, when released, can produce auroræ. This might be accomplished by high-altitude detonations designed to release the natural trapped radiation. Most calculations seem to indicate that the density of trapped radiation would be highest in those tubes of force which enter the Earth at approximately the latitude of the auroral zone. It is even possible that at certain times the density of trapped particles in these tubes of force is determined by the diamagnetism of the plasma gas, and that these tubes of force can only be filled to the point at which this demagnetization makes the tube unstable. This condition of instability will occur at a somewhat smaller density of particles than that at which the energy density of particles is equal to the energy density in the Earth's magnetic field. For an auroral tube of force reaching a radial distance of approximately 4 Earth's radii and entering the Earth at a latitude of 60°, this critical maximum energy density of particles would be approximately 10^{-6} ergs/cm.^{3}. If the particles consisted, say, of 1-MeV. electrons, the density would then be 1 particle cm.^{3}. It should be noted that this limit is in agreement with that derived from the condition that the particles cannot contribute more than about 1 per cent to the field at the surface of the Earth. That it should be possible to release this trapped radiation by explosive means now at hand can be seen from the following argument.

Since the energy density of particles cannot exceed the energy density in the Earth's field, an explosion in which an appreciable fraction of the stored energy in the Earth's magnetic field is dissipated in kinetic energy should allow the distortion of the field to the extent that particles may be released. The energy which is stored in the magnetic field of the Earth external to the surface is 10^{25} ergs. This corresponds to the explosive energy of a 200-megaton atomic weapon. Since only a very small fraction of the total energy stored in the field need be supplied in a conducting plasma, it is clear that a very much smaller explosion than 200 megatons would produce geomagnetic and geophysical effects. In an explosion, an appreciable fraction of the gas involved is ionized, and therefore constitutes a conducting plasma. If such a conducting plasma with kinetic energy is released in the region of the *E*- or *F*-layer, the plasma will be trapped in the lines of force of the magnetic field and distort this magnetic field into a large bubble. Part of the energy of the bubble should then be propagated as an Alfvén wave along the tube of force, going from one hemisphere to the other. The initial effect of the explosion with respect to the trapped radiation would be that those particles with pitch angles which became flat in the vicinity of the magnetic bubble would no longer be reflected and would be released from the trapped radiation field. Since the particles spend most of their time at the regions of reflexion, a relatively large number of particles would be released from the local region by such a plasma explosion. It should be pointed out that this explosion must be carried out at a high enough altitude to enable the kinetic energy of the explosion to be converted into distortion of the magnetic field through the interaction of the plasma and the magnetic lines of force, and that collisions with residual gas of the atmosphere do not dissipate this kinetic energy in heat. For these conditions, a high-altitude nuclear explosion would be ideal. We shall see shortly that such a high-altitude explosion, however, injects so many high-energy beta-decay electrons that the effects of releasing the trapped radiation would be obscured by the injection of radioactive particles from the atomic debris.

The velocity of the bomb-injected particles is on the average greater than the velocity of the Alfvén wave, and the injected particles will therefore reach the conjugate point before the Alfvén wave can release the natural trapped radiation.

In any high-altitude explosion, in which an appreciable amount of energy is coupled between the conducting plasma and the magnetic field, one would expect to see the following geomagnetic effects:

(1) The production of auroræ at the region of explosion and also at the conjugate point in the opposite hemisphere.

(2) Magnetic disturbances at the surface produced by the primary effects of the flowing charges in the ionosphere, and possibly by secondary effects caused by the release of additional particles as the magnetic

REGION OF AURORA
NUCLEAR EXPLOSION
EARTHS SURFACE
EQUATOR
JOHNSTON ISLAND
APIA

Fig. 1. Geometry of the Johnston Island nuclear explosion

field of the Earth becomes disturbed from the loss of the Van Allen radiation initially released.

(3) The propagation of an Alfvén wave, produced by the motion of the bubble along the lines of force. The Alfvén wave in this case may be thought of as a string wave in which the tension in the string is the tension in the lines of force, and the mass per unit length of the string is represented by the mass density of ionized particles which will be frozen to the line of force.

(4) Ionospheric radio effects. Because of the ionization produced by the released particles, which may have ranges up to several grams per square centimetre, there should be pronounced changes in the ionosphere, as evidenced by changes in the critical frequency of ionosonde soundings at both ends of the line of force.

(5) The presence in the upper atmosphere of the released radiation. This radiation could perhaps be studied from very high-altitude balloons, since the trapped radiation, once disturbed in pitch angle and allowed to penetrate down into the atmosphere, may have ranges in excess of several grams per square centimetre and could be detected at altitudes of 140,000–150,000 ft. by high-flying balloons. The bremsstrahlung from electrons stopped at very high altitude can be observed from balloons at 70,000–100,000 ft.

(6) The production of an artificial whistler by the propagation in the whistler mode of energy along the tube of force. This could perhaps be detected by the reception of audio electromagnetic waves at both ends of the tube of force.

(7) The effects can be used to locate magnetic conjugate points precisely.

Of the effects listed, we believe that the study of a 'point source' aurora is perhaps the most interesting, and an explosion properly carried out should be able to settle the question of whether auroræ can be produced by release of trapped radiation.

We shall now discuss the differences between nuclear explosions and those produced by chemical explosions in the *E*- or *F*-layer.

The Nuclear Explosion at Johnston Island

It has recently been reported in *Nature*[1] that at the time of the Johnston Island nuclear explosion geomagnetic disturbances were observed at the Magnetic Observatory at Apia; including visible auroræ, radio fadeouts, and a quite unusual magnetic storm lasting for several hours. We believe that the effects observed at Apia are in very good agreement with those expected from the injection of charged particles by the nuclear explosion at Johnston Island, rather than by the release of trapped radiation already present in that tube of force. The fact that the Apia observations were due to the Johnston Island explosion is indicated by the almost exact coincidence in time of the events and by the fact that such effects at low latitude as those observed at Apia on this occasion are extremely rare, only one previous case having been observed at this station. The time of the Johnston Island explosion was given as 12.52 a.m. Hawaii time[2], observed by an airline pilot flying over Hawaii who noted the nuclear explosion. This is 10.52 G.M.T., and the first observation of geomagnetic effects at Apia occurred at 10.51 G.M.T., August 1, 1958. The auroral display was observed in the west and south-west directions from Apia, and we have tried to calculate the impact zone of particles arriving in the vicinity of Apia along a line of force intersecting the northern hemisphere at 100 miles above Johnston Island. Fig. 1 shows a cross-section of the Earth showing the line of force along which the Johnston Island particles would be propagated. The thick line shows the region in which the particles would enter the atmosphere near Apia, and would produce auroræ. The altitude of the nuclear explosion is assumed to have been 100 miles—the altitude reported in newspaper accounts. The explosion must have occurred higher than 70 miles in order to be seen line-of-sight from Hawaii. The altitude at which the explosion occurs is that altitude at which flat pitch angles can occur (that is, orbit perpendicular to the line of force), and in fact flat pitch angles and reflexion cannot occur at a higher altitude than the altitude of the explosion. Steeper pitch angles, of course, can occur, and these will correspond to particles which penetrate deeper into the atmosphere at the other end of the line of force. At the atmospheric densities encountered at 100 miles altitude, the life-time of a 1-MeV. electron for loss of energy is approximately 20 sec. The easterly precession of the electrons, therefore, can only occur in a time corresponding to this life-time for loss of energy of the injected particles. The particles which will be propagated along the tube of force will be the beta-particles from the radioactive decay of fission or fusion products, depending on the nature of the bomb. These will be electrons and a few positrons in the 1-MeV. energy-range, and because the initial period of an atomic explosion is the most active one, the duration of the aurora will reflect the radioactivity of the products of the explosion. We believe that the five-minute duration of the aurora is a reflexion of this radioactivity rather than a life-time associated with the transmission or trapping of the particles.

Fig. 2 shows a plot of the expected impact area of the particles from the explosion, and the area in which the aurora was actually observed from Apia. The agreement is quite good, but the observed aurora seems to be north-west of the place expected from geomagnetic considerations. In order to calculate the geomagnetic conjugate point, we have used the position of the cosmic-ray equator, believing that it indicates best the direction of the tube of force. The disagreement between the calculated and observed impact areas may reflect uncertainty in our knowledge of the Earth's magnetic field, but might also indicate that the explosion, instead of occurring directly over Johnston Island, occurred somewhat to the south-west. Since the position of the impact zone agrees so well with the calculated position, one must inquire whether those particles arriving at Apia were released from the tube of force or injected by the atomic bomb. We have previously seen that

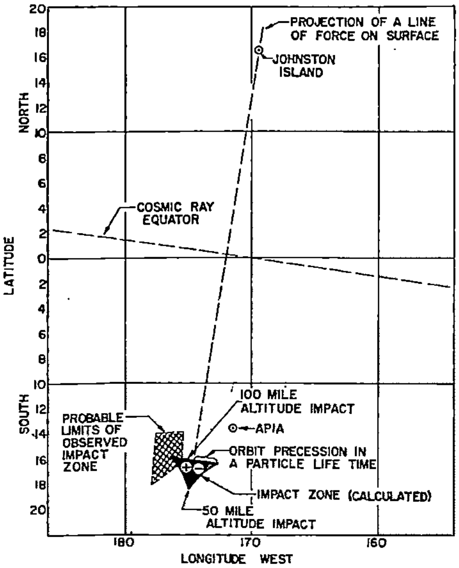

Fig. 2. Predicted and observed impact zones for the Johnston Island nuclear explosion. + and − refer to impact zones for positive and negative particles respectively

the total trapped radiation in the Earth's field represents perhaps 1,000 moles of particles. Because of the beta-decay following fission, approximately 5–10 moles of particles may be injected by an atomic weapon for each mole of fissionable material used. To get an idea of the order of magnitude of the injected *vs.* released particles, one might consider an explosion large enough to produce a kinetic energy equal to the Earth's magnetic field. This would presumably release all the trapped Van Allen particles, but it would in fact inject approximately 25,000 moles of beta-decay electrons, an order of magnitude more than the number of trapped particles already there. Since in the Johnston Island event we are considering a tube of force which reaches an altitude of only 400 miles at the equator, it cannot contain Van Allen radiation. The Iowa group finds the lower edge of the radiation belt at 1,000 km. It is quite clear in this case that many more particles will be injected than will be released, and that the auroral effects reflect these injected particles.

Chemical Explosions at High Altitudes

A recent *IGY Bulletin*[3] has reported observation of a luminescent cloud lasting three to four minutes following the explosion of a high-altitude sound-ranging grenade exploded at about 75 miles altitude. It seems possible to us that this luminescence could be produced by the release of naturally occurring Van Allen radiation. The rocket experiment was carried out at Woomera, Australia, at the end of a tube of force known to be populated with natural radiation. For an ideal experiment, with a chemical explosion at high altitude, one would attempt to carry out the explosion above 100 miles, and preferably at about 200 miles, in the *F*-layer of the ionosphere. It would also be desirable to have the ionization in the explosion as high as possible. Perhaps the addition of easily ionized material could increase the ionization in the chemical explosion. In the chemical explosion, however, the aurora observed, particularly at the opposite end of the tube of force, should be a definite proof of the possibility of its production by release of natural radiation. The detonation of a chemical weapon does not involve the problem of injection of charged particles from a nuclear bomb, but does suffer from the lower ionization in the chemical explosion. We feel that the detonation of approximately a ton of chemical explosive at 200 miles would produce a crucial test of this point.

SPACE RESEARCH

By Dr. R. L. F. BOYD
Department of Physics, University College, London

THERE has probably never been a more rapid and far-reaching revolution in scientific technique than has been brought about by the advent of space-probing rockets. Between the end of the Second World War and the start of the International Geophysical Year more than one hundred upper atmosphere rockets were launched and a great deal was learnt, both about those regions and about the solar spectrum. In this period many techniques were developed which have been employed with even greater success in more than twice that number of rockets launched during the International Geophysical Year. With the use of geophysical rockets by the Russians, and especially of *Aerobee-Hi* by the Americans, the region between 100 and 300 km. above the Earth's surface has been explored with some thoroughness for the first time. At Churchill—in the auroral zone—and by launchings from a great variety of places, results have been obtained on the variations of many quantities with time of day, season and latitude. Most of the rockets fired had a useful life of only a few minutes, but this International Geophysical Year will be remembered also for the first launchings of artificial Earth satellites which made it possible to obtain world-wide coverage of the regions above 200 km. for weeks on end. During this time eight instrumented satellites have been launched and at least fifteen distinct objects have been placed into orbit around the Earth. In operation 'Farside', a multi-stage rocket launched from a balloon reached a height of 4,000 km.; more recently the 'Pioneer' Moon shots penetrated to more than 100,000 km., while the recent Russian space probe passed close to the Moon and entered a solar orbit.

On a more modest scale, in Britain, the International Geophysical Year has seen the successful initiation of the Royal Society - Ministry of Supply research programme using *Skylark*, and the first launching of *Black Knight*—a vehicle with great potentialities should it eventually become available for pure scientific research.

With the feasibility of direct experimental observation of the outer fringe of the Earth's atmosphere and of the nature and density of the corpuscular and electromagnetic radiation in the space beyond amply demonstrated, it was appropriate that a discussion of "Space Research" should be arranged by the Royal Society. In planning this two-day discussion, which was held on November 12 and 13, it was borne in mind that the possibility of direct study of the Moon and the nearer planets could not be long delayed, while the prospects for extensive astronomical observations carried out above the atmosphere were great. The kinds of scientific problems which could profitably be attacked by rocket techniques were examined, and the limitations imposed by the requirements of orbit and aspect control, vehicle tracking, data recovery and instrument design were discussed.

Although an invitation had been given, no delegate from the Soviet Academy of Sciences was present. However, the conference was fortunate to have present Dr. H. E. Newell of the Naval Research Laboratory, Washington, who was able not only to present many American results, but also to give a broad account of the future plans of the United States. The discussion was opened by Prof. H. S. W. Massey (University College, London), who reviewed briefly the scope of impending space research, mentioned the rapid technical advances that made these discussions important, and expressed his surprise to find himself speaking of developments in planetary studies that a year or so ago would have been simply science fiction. Experimental results and theoretical considerations relevant to an understanding of the atmosphere above 100 km. were discussed by Prof. D. R. Bates (Belfast). He limited his remarks to the composition and temperature of the region and assumed a static model. The composition is determined partly by diffusive separation, which has been demonstrated both by bottle-sampling and mass-spectrometric measurements. At 150 km. the argon–nitrogen ratio has fallen to one-sixth of its ground-level value. In a static atmosphere such diffusive separation would result in the concentration of hydrogen at 400 km. being comparable with that of atomic oxygen. However, a net loss or gain of hydrogen to or from the interplanetary regions would greatly affect the concentration gradient, and there is still a need for more experimental data.

Above 100 km. oxygen is largely dissociated and above 300 km. is probably more than ten times as abundant as atomic nitrogen. Below 300 km., due to rapid recombination of atomic nitrogen by $N + O_2 \rightarrow NO + O$ and $N + NO \rightarrow N_2 + O$, nitrogen is largely molecular and has a correspondingly small scale height. The ionic constitution up to 200 km. has been found to be principally NO^+ probably formed by $O^+ + N_2 \rightarrow NO^+ + N$.

The rise of temperature above 100 km. has been found to be much greater than was commonly supposed some years ago. The fall in the concentration of electrons above the *F*-layer—measured out to 750 km. by the Russians—suggested a temperature between 1,500° K. and 2,000° K. at this height. The large temperature gradient indicates a downward heat flux of about 2 ergs/cm.^{2}/sec. and poses a considerable problem as to its origin. Prof. S. Chapman thought that the solar corona extends as far as the Earth's orbit, and, with a temperature of a quarter of a million degrees, is the source of this energy. The high maximum temperature of the corona—about a million degrees—was thought to be due to high-energy particles passing through it, though opinions differ as to whether these particles came from inside or outside the Sun. Prof. Chapman reviewed the conditions existing in the corona with special emphasis on the problem of determining its thermal conductivity in view of the existence of velocity gradients and magnetic fields. The solar magnetic field tends to rotate the corona with the Sun but probably does not penetrate very far out as it will set up an opposing ring current. The density of the corona beyond 15–20 solar radii is in doubt because of the centrifugal forces due to its rotation. However, its conductivity is, of course, independent of its density.

In spite of many efforts to obtain information on the concentration of interplanetary dust, difficulties of interpretation have prevented a consistent figure from being obtained so far. This is a pity because in sufficient, though perhaps rather unlikely, concentrations the dust might play an important part in cooling the corona. In the absence of such cooling, Prof. Chapman thought that the Earth must be regarded as a cool spot in an immensely hot gas and its atmosphere must rise in temperature from about 200° K. at 80 km. to 200,000° K. at great distances. The huge scale height implied suggests that the Earth's atmosphere may extend even as far as the Moon. The conductivity of the atmosphere due to hydrogen flowing into it might be increased five-fold because the atoms carry with them their heat of recombination.

Prof. C. F. Powell (Bristol) described the great potential value of artificial satellites to the study of fundamental problems in the physics of cosmic rays and very high-energy particles. He saw a limit to the particle energies attainable by contemporary methods at around 100 BeV. but in cosmic rays energies up to 10^9 BeV. are found. The satellite laboratory may well be the only place in which experiments on such energetic particles can be conducted for many years to come.

The abnormally high concentration of lithium, beryllium and boron in the cosmic-ray flux compared with their universal abundance is probably due to fragmentation of heavier particles during their interstellar journey. More satellite results are needed to confirm this. It seems probable, however, that a mean life of the order of 10^8 years is indicated. The long mean life and isotropic distribution suggest that the particles are stored in the fields of the galactic halo. Two possible sources of injection of these rays were contemplated, namely, supernovæ and in red and super-giant stars. Discrimination between these sources could be carried out by obtaining the mass spectrum of the rays well above the atmosphere. Thus a supernova source would result in rays rich in heavy elements, for example, thorium-254. Giants would give a spectrum similar to that of flare particles.

Satellites are particularly valuable in studying corpuscular and electromagnetic radiation from flares because of their unpredictable occurrence.

In a paper concerned with the study of the Moon and the nearer planets, Prof. T. Gold (Harvard) re-emphasized the need to study the density, motion, temperature and velocity distribution of material in the interplanetary regions. The magnetic field frozen into solar streams may entrap particles with energies ranging from 10 keV. up to 30 BeV. The importance of planetary and interplanetary magnetic fields places a high priority on a magnetometer in the allocation of the pay-load of deep-space probes.

A study of the Moon may be of value in helping us understand the geological history of our own planet. Facsimile scanning of the surface should be especially aimed to resolve the question of the origin of the lunar maria. A lunar satellite might detect a transient atmosphere on the Moon. Such an atmosphere could arise from gas emitted from the surface, or, when the Moon passed through a solar stream, as much as 3×10^5 particles/sec. might be found if the high-velocity stream were reflected with only thermal energy.

Satellite studies of the atmospheres of Mars and Venus could be carried out by spectrometric and mass spectrometric techniques. Even an Earth satellite could be of value in spectrometry of Mars, for example, since it would remove the confusion due to telluric lines. It would be interesting to look for suggestive traces of organic compounds of biological origin. The presence of water and nitrogen in the Martian atmosphere should be examined.

Prof. F. Hoyle (Cambridge) considered problems much more remote in space but in some cases quite as pressing in any plans for future space research. He reviewed the serious limitations to terrestrial astronomy occasioned by absorption, refraction, and scattering of light in the atmosphere. Astronomical observations made above the atmosphere with a 20-in. telescope would already have advantages over any made from a terrestrial observatory—quite apart from the unrestricted range in wave-length.

Use of narrow-band ultra-violet detectors, for the Lyman series, for example, would improve the signal/noise ratio for observation of distant objects because the red shift would separate the distant source from local scattering.

Studies of white dwarf stars in the ultra-violet would be especially valuable both because of their greater brightness in this region and because of the important nuclear reactions occurring in them. On the other hand, the use of infra-red detectors would make it possible to penetrate the dust clouds from which stars are formed, and would thus assist in an understanding of this basic cosmic process.

In the study of the Crab nebula and of the galaxy's gaseous envelope, where there are high-energy electrons, X-ray and γ-ray astronomy would be invaluable. Prof. Hoyle mentioned several examples of important cosmological data which we happen to possess simply because the atmospheric window is fortuitously well placed or because the limits of terrestrial vision are by chance favourable for observation. The argument that much more vital information awaits the extension of these limits seems inescapable.

Prof. A. C. B. Lovell was prevented by ill-health from attending, his place being taken by Dr. J. G. Davies of the Jodrell Bank Station, who pointed out that terrestrial radio astronomy is subject to the same basic limitations as optical astronomy. He thought that the greatest value of extra-terrestrial radio astronomy will lie in the extension of the useful spectrum beyond the ionospheric absorption limit, and in the possibility of close approaches to the Moon and planets.

Representatives of the Royal Aircraft Establishment discussed a number of practical problems in connexion with space probes and satellites. Dr. A. W. Lines stressed that stringent orbit and aspect control will be required in the near future. He set out to show how these requirements might be met in a satellite or space probe with an initial all-up weight of less than 100 tons and a first-stage thrust of about a quarter million pounds. Stabilization might be required in terrestrial, space (sidereal) or solar axes, and could conveniently be achieved by employing jet reaction initially, with motors for angular momentum storage after most of the angular momentum had been removed. Special emphasis was placed on a space stabilization system using two stars as reference points. The photoelectric equipment would be associated with gyroscopes to take control during eclipse of the stars. The precession-rate for the gyroscopes could be 'learnt' by the servo system by reference to the stellar vectors.

Mr. W. T. Blackband discussed a system for the recovery of information from vehicles as far away as the nearer planets. For a triode receiver, noise from all sources is a minimum at about 200 Mc./s., and corresponds to a source temperature around 750° K. Maser systems would give a better figure at very high frequencies. For a dish 10 m. in radius, a 10-W. transmitter and 1 c./s. band-width, Mr. Blackband obtained a signal/noise ratio of 1·2 at 10^6 km. It is evident that recovery of information is a major problem for planetary probes and recourse must be had to any or all of the following measures : considerable increase in transmitter power, even more drastic reduction of band-width, the use of masers, the use of directional aerials at the transmitter.

Position determination could be achieved by an interferometer calibrated against radio stars. A precision of 15 sec. of arc might be obtained. Stabilization of the transmitter to one part in 10^9 would enable range to be found by Doppler methods to an accuracy of 1 km. per hour of travel.

Techniques of physical measurements were reviewed by Dr. R. L. F. Boyd (University College, London). Two techniques, conspicuously absent in much work to date, are microwave spectrometry and the Langmuir probe. The former may ultimately prove a means of assaying directly the nitric oxide which plays such an important part in the ionosphere below 200 km. Some of the work at University College, London, was described. In 1959, *Skylarks* will be fired, equipped with Langmuir probes. Laboratory studies have shown that this technique may usefully be developed not only to give information on the concentration of electrons and temperature of the upper atmosphere but also to give concentration of negative ions and some degree of mass analysis. The extension of the technique to satellites and deep-space probes was discussed. Analyses of energy distributions at satellite velocities would enable discrimination to be made between oxygen and nitrogen atoms.

Considerations of Debye length, photo-emission and the return of collected current show that the technique might be applicable to a study of the solar corona and the energy distribution in solar corpuscular streams.

Prof. J. Sayers described the ionospheric work using *Skylark* rockets at the University of Birmingham. He showed a curve for electron density in a night sporadic-*E* cloud, obtained at Woomera on the Rocket World Day. It was remarkable for the thinness of the cloud—less than 3 km. Concentrations were similar to normal daytime *E* maxima. The method employed involved determination of the local refractive index from the frequency of a radio-frequency oscillator, the tank circuit of which included the insulated nose-cone of the rocket as part of its reactance. Prof. Sayers also showed a *Skylark* nose-cone instrumented with an ion spectrometer of unique design. This spectrometer is a pulsed ion chamber of 2,000 cm.^{2} aperture. It is ejected from the rocket on a long flexible cable so as to avoid contamination with rocket gases.

Probably the most dramatic and exciting discovery of the rocket and satellite programme of the International Geophysical Year has been Van Allen's work with the *Explorer* satellites, now corroborated by *Sputnik* 3. The discovery of the Van Allen belt, as it has come to be called, was made with *Explorer* 1, the Geiger counters of which were soon saturated with the intense radiation. To amplify the results from *Explorers* 1 and 3, *Explorer* 4 was instrumented with two scintillation counters (one plastic and one cæsium iodide) and two Geiger counters (one shielded). It was launched at an inclination of 51° and the results were recorded on magnetic tape, read out on command.

That the radiation belt reached a maximum intensity of more than 10,000 counts/min. at about an Earth's radius above the equator was confirmed by *Pioneer* 1. *Explorer* 1 showed evidence of a connexion between the intensity and auroral activity (and therefore solar streams). *Explorer* 4 indicated in addition the presence of a more penetrating component than the auroral electrons.

It was suggested that the radiation is largely due to solar ionized gas trapped in Störmer orbits. A rough computation of the relaxation time of the ionization gives 10^7 sec., far too long for auroræ to result directly from influx into the belt. It is suggested that the auroræ are due to leakage from the belt along the lines of magnetic force and that the increase at the advent of a solar stream is due to deflexion of the lines of force, analogous to a squeezing of the reservoir.

Mr. D. G. King-Hele of the Royal Aircraft Establishment, Farnborough, presented his results from observations of the orbits of *Sputniks* 2 and 3. The irregularities in motion can be attributed to varying air density, the westerly wind of the Earth's rotation and the second harmonic of the gravitational field. The results show that changes in air density at perigee are immediately reflected in change of time of meridian passage. The westerly wind causes a perceptible change in orbit inclination, while the rate of precession leads to an accurate estimate for the Earth's oblateness. If it is assumed that only the second harmonic of the gravitational field is significant, a new value of 1/298·16 is obtained for the elipticity compared with 1/297·6. Mr. King-Hele was of the opinion that to this degree of precision it is permissible to ignore higher harmonics. No inconsistency arises in the results obtained from satellites of various inclinations when this is done.

Two papers were presented by Dr. Newell. In the first he reviewed some of the results from inboard satellite instruments, other than cosmic-ray measurements. In the *Explorers*, micrometeors had been studied by the microphone method and environmental measurements had been made. Soon it was hoped to launch satellites to study cloud cover, the terrestrial radiation balance and magnetic field. Some micrometeor results have come from non-orbiting *Vanguards*. A flux of about $2{\cdot}5 \times 10^4$ kgm./day has been estimated but there are serious discrepancies with Soviet results.

The results on density obtained from rockets and satellites are consistent, figures of $2{\cdot}8 \times 10^{-13}$ gm. cm.$^{-3}$ at 228 km. being obtained from air drag and 1×10^{-13} and $8{\cdot}8 \times 10^{-15}$ gm. cm.$^{-3}$ at 260 km. and 355 km. respectively, from ion gauges in *Sputnik* 3.

Ionization shows a slow decline above the *F*-layer, and composition measurements using a radio-frequency ion spectrometer in *Sputnik* 3 show the oxygen ion to be the predominant ion from 250 to 950 km. The ratio of N^+/O^+ at 230 km. was found to be 3·7, rising by a factor of two at about 700 km.

In his second paper, Dr. Newell reviewed the future of American research under the National Aeronautics and Space Act. The terms of reference include: (1) expansion of human knowledge of the atmosphere and space, (2) aircraft, (3) space vehicles, (4) long-range uses of space for peace, (5) co-operation with other nations. The programme planned amounts to a review of all the basic physical studies which have become possible now that space research by rocket vehicles has become a reality.

NEWS and VIEWS

Geological Society: Awards for 1959

THE Geological Society of London has made the following awards for 1959: *Wollaston Medal* to Prof. Pierre Pruvost, professor of geology at the Sorbonne, Paris, for his researches in stratigraphy and palæontology, with special reference to his work on the Carboniferous rocks of Europe, and his stratigraphical investigations of the rocks of Brittany; *Murchison Medal* to Prof. S. E. Hollingworth, professor of geology at University College, London, for his contributions to stratigraphy, glaciology and geomorphology in north-west England and the Midlands; *Lyell Medal* to Prof. D. Williams, dean of the Royal School of Mines, for his contributions to geology, especially as applied to the discovery and exploration of mineral deposits; *Bigsby Medal* to Prof. B. C. King, professor of geology, Bedford College, London, for his contributions to the structure and petrology of Africa, especially of Nigeria, Uganda and Bechuanaland, and to the interpretation of rock transformations, ancient volcanoes and metamorphic tectonics in Scotland; *Wollaston Fund* to Dr. M. H. P. Bott, lecturer in geology in the University of Durham, for his application of geophysical methods in the elucidation of geological structures and particularly the structure of granite masses; *Murchison Fund* to Dr. D. T. Donovan, lecturer in geology in the University of Bristol, for his work on Mesozoic stratigraphy, palæogeography and palæontology, particularly in regard to the ammonites; a moiety of the *Lyell Fund* to Mr. C. O. Harvey, chemist to the Geological Survey of Great Britain during 1934–58, for services in aiding geology by chemical analyses of rocks and minerals; another moiety of the *Lyell Fund* to Dr. W. H. C. Ramsbottom, of the Geological Survey of Great Britain, for his contributions to systematic and stratigraphical palæontology, especially for his work on the Lower Palæozoic Crinoidea and on Carboniferous faunas.

U.S. National Reliability Award : Mr. R. Brewer

Mr. Ralph Brewer, of the General Electric Company Research Laboratories, Wembley, has been awarded the 1958 National Reliability Award for his paper entitled "Life Tests of Electron Tubes and the Analysis of Failure Causes", which was read at the Fourth National Symposium on Reliability and Quality Control in Electronics, held at Washington in January 1958. The award is made to the author of the best technical paper presented at this annual Symposium. Mr. Brewer's paper was the only overseas contribution in the total of fifty papers read. The symposium is jointly sponsored by the American Institute of Electrical Engineers, the Institute of Radio Engineers, the American Society for Quality Control and the Electronic Industries Association. Mr. Brewer is a member of the principal scientific staff of the General Electric Company's Research Laboratories, which he joined in 1937 to work on illumination engineering. During the War he transferred to electronic valves and worked on early radar magnetrons. After the War, he took charge of valve reliability studies, which have played an important part in the development of improved valves. His work has now extended to cover the study of the survival characteristics of transistors and related semiconductor devices as well as the general reliability problems of electronic systems.

National Institute for Research in Dairying : Prof. R. G. Baskett

Prof. Ronald Gilbert Baskett has been appointed director of the National Institute for Research in Dairying, University of Reading, as from August 1, 1959. He succeeds Prof. H. D. Kay, who has recently retired (*Nature*, 181, 1506 ; 1958). Dr. A. T. R. Mattick is at present acting director. Prof. Baskett is now professor of agricultural chemistry, the Queen's University of Belfast, and head of the Chemical and Animal Nutrition Division of the Ministry of Agriculture for Northern Ireland. He was born in 1901, and educated at King Edward VI Grammar School, Chelmsford, and University College, Reading, where he received his early training in chemistry with Prof. H. Bassett and Prof. H. A. D. Neville. His interests have centred in animal nutrition, particularly mineral metabolism. He has been especially concerned with pig husbandry and is at present a member of the Technical Committee of the Agricultural Research Council on Pig Research. Prof. Baskett has had long administrative experience in Northern Ireland coupled with teaching in the University of Belfast and examining in other universities. He also served with distinction as agricultural attaché at the British Embassy in Washington. His world-wide contacts with workers in the same field will be of great value in his new post.

Animal Husbandry at the Royal Veterinary College : Prof. J. A. Laing

The late Prof. N. J. Scorgie (see *Nature* of January 24, p. 220) has been succeeded in the Courtauld chair of animal husbandry at the Royal Veterinary College, London, by Dr. J. A. Laing, reader in veterinary science in the University of Bristol. Prof. Laing, who graduated in Edinburgh in 1941, took an early interest in problems of bovine infertility, and as an Aleen Cust Memorial Scholar worked under John Hammond at Cambridge, under whose guidance he obtained his Ph.D. in 1944. He remained in Cambridge studying particularly spermatozoa, as a research officer and then as veterinary investigation officer of the Ministry of Agriculture, until 1949, when he joined the staff of the newly formed Veterinary School of the University of Bristol. His main research interest did not waver from the general problems of animal breeding and genital infection and he attained a nation-wide and international reputation in this respect. In 1954 he was awarded a Churchill Fellowship to study in Copenhagen, and has acted as a consultant to the Food and Agriculture Organization of the United Nations, which sponsored an assignment for him to advise the Republic of Dominica on cattle infertility and allied problems during 1957–58. He was awarded the status of reader in 1957. His published works include the book "Fertility and Infertility in the Domestic Animals" (1955). Prof. Laing's breadth of experience in the field of animal reproduction will be of value in helping to develop the new field station of the Royal Veterinary College recently opened at Potters Bar.

Spert-III achieves Criticality

The special power excursion reactor test No. 3 (Spert-III), a versatile research facility developed for studying nuclear reactor safety at the U.S. Atomic Energy Commission's National Reactor Testing Station, Idaho Falls, achieved criticality on December 20. Spert-III is one of a series of reactors designed and developed by Phillips Petroleum Co. as part of the Atomic Energy Commission's programme to find basic explanations for the behaviour of reactors under runaway conditions. All operations are conducted by remote control, since some of the tests approach destruction of the reactor. This facility provides the widest practical range of control over three variables—temperature, pressure, and rate of flow of coolant. The plant is expected to contribute significantly to a better understanding of reactor self-limiting and occasional instability characteristics exhibited in an earlier experimental reactor, Spert-I.

Spert-I, which began operation in July 1955, was the first of a series established to investigate potential hazards associated with the broad class of heterogeneous, water-moderated, enriched-fuel reactors. Spert-II, which is still under construction, is intended to continue similar studies with special emphasis on how various moderators and reflectors, including heavy water, influence reactor behaviour. Tests in Spert-I, using a simple open-tank system, are generally characterized by sudden power rises (one reaching $2 \cdot 8 \times 10^9$ watts) that are arrested by the inherent self-limiting tendency of the reactor itself. Without any manipulation of the control rods, reactor power reaches a peak in a fraction of a second and drops off to much lower but generally steady levels. In some cases, however, instabilities also are observed following the power peaks. Some of these are divergent oscillations that could probably destroy the reactor, despite its self-limiting characteristics, if allowed to continue. The precise causes of self-limitation and of these power instabilities are not known, but form the principal objective of the present project.

Atomic Energy Information

In order to make atomic information more easily available, the U.K. Atomic Energy Authority has decided to make fuller use of microphotography. The effect of this will be to make all non-secret reports which have been prepared since 1947 readily obtainable. Complete sets are also being presented to a number of other countries and to certain international agencies. In addition to this, the Authority is increasing its facilities for supplying reports in conventional form as they are prepared. From February 16 a large number of unclassified and declassified reports, which have hitherto been obtainable only on loan from Atomic Energy Authority libraries, will be available in micro form. Arrangements have been made with Micro Methods, Ltd., of East Ardsley, Wakefield, Yorks, for the production of microcopies on card of all unclassified and declassified reports issued between 1947 and December 1956 and, on a continuing basis, of those reports issued since 1956 which are not available on sale from H.M. Stationery Office. Microcopies may be purchased from Micro Methods.

Sands of Forvie Nature Reserve

SANDS of Forvie, Aberdeenshire (1,774 acres), which has been declared a new Nature Reserve by the Nature Conservancy, under an agreement with the Walker Scottish Estates Co., Ltd., the owners, lies on the coast near Newburgh, between the mouth of the River Ythan and the village of Collieston. It consists of a broad foreshore backed by a line of dunes, behind which are slacks and more stable dunes passing inland to dune heath and rough pastures. To the north of the low sandy shore and the seaward dunes there are cliffs of schists and gneisses overlain by boulder clay. This rocky part of the coast includes Hackley Head and Hackley Bay. Inland from Collieston are two small freshwater lochs—Sand Loch and Cotehill Loch.

The chief botanical interest lies in the plant communities of the dunes. Marram grass (*Ammophila arenaria*) is the dominant species on the shifting dunes, while the sand sedge (*Carex arenaria*), the jointed rush (*Juncus articulatus*) and silver weed (*Potentilla anserina*) are generally among the earliest established dominants on the sheltered, moist dune plains. Mat grass (*Nardus stricta*), crowberry (*Empetrum nigrum*), creeping willow (*Salix repens*), cross-leaved heath (*Erica tetralix*) and ling (*Calluna vulgaris*) become prominent in later stages of the succession inland to the fixed dunes. The crowberry plants, conspicuous over large areas, are usually associated with lichens, forming a distinctive *Empetrum*-lichen heath community. The lesser spearwort (*Ranunculus flammula*) and the toad rush (*Juncus bufonius*) are characteristic of the wetter dune hollows which are often locally rich in mosses. Birds breeding within the area include eider (a particularly large nesting population), shoveller, shelduck, red grouse, little tern, arctic tern, common tern, sandwich tern, and fulmar. The whole area offers excellent opportunities for developing physiographical and biological observation and research. Among the dunes there are important Late Bronze and Early Iron Age sites which have yielded stone implements and pottery, and comprising stone circles, a flat ring cairn and kitchen middens.

Microbiological Defence Research

IN reply to a question in the House of Commons on January 26 regarding the Microbiological Research Centre and the Chemical Defence Experimental Establishment, the Minister of Supply, Mr. A. Jones, said that the Ministry of Supply Establishments at Porton are mainly engaged in research on defensive problems of microbiological and chemical warfare. The investigations are essentially directed towards assessing the threat and providing defences against it, and most of the results obtained are published in the scientific literature. The danger from botulinus toxin is included, but this danger has been grossly exaggerated, since the toxin cannot be easily disseminated and is not self-propagating. Useful defensive measures against it are known.

Scientific Research in South African Universities

THE Register of Current Scientific Research at South African Universities, 1957 (pp. viii+198. Pretoria: South African Council for Scientific and Industrial Research, 1958), is the fifth of the series of annual volumes listing research projects in the natural sciences being undertaken at South African universities and intended to meet the needs of research workers in South Africa and elsewhere. The information is given in the language in which it was received from the universities, but an English translation of Afrikaans entries is provided, and the alphabetical order of the subject-matter is determined by the English heading. As in previous volumes, entries are grouped under subjects, corresponding roughly with departmental divisions in the universities, and under these headings are arranged all the research projects in that subject in each university in turn. There are also an author and a subject index.

The Nucleus

IN view of the spectacular advance made in recent years in the field of genetics, there is a growing need for more information about the physical basis of genetic phenomena. *The Nucleus*, an international journal of cytology and allied topics, recently published, has this aim (*The Nucleus*, 1, No. 1; June 1958. Pp. 152. Calcutta: Dr. A. K. Sharma, Editor, Botany Department, The University, 1958; annual subscription 10.50 dollars or Rs. 46.00). The contributions in the first issue deal with descriptive cytology, chromosome dynamics, chemical and radiation effects on chromosomes and the mitotic process, and include a scholarly study on the possible role of nuclear membrane detachment in cytoplasmic organization. The international advisory board consists of H. Kihara (Japan), H. P. Riley, B. P. Kaufmann and J. H. Taylor (United States), F. Oehlkers (Germany), A. Löve (Canada) and M. J. Sirk (Holland). The editor is Dr. A. K. Sharma. The style of printing and the photographic reproductions can compare favourably with any other well-established publication.

Fourth Congress on Theoretical and Applied Mechanics

THE fourth Congress on Theoretical and Applied Mechanics was held at the Bengal Engineering College, Howrah, during December 28–31, under the presidency of Dr. S. R. Sen Gupta, director of the Indian Institute of Technology, Kharagpur. About two hundred and fifty scientists and engineers, including members from Australia, Burma, Czechoslovakia, Egypt, Hungary, Italy, Japan, Poland, the United States and the U.S.S.R. attended. Some forty original papers were read, on subjects including finite deformation, visco-elasticity, stress waves, stresses in strips, columns and disks, plasticity, elasto-porosity, vibration and stability, fluid-flow, ballistics and statistics.

Dr. A. N. Khosla was elected president for the next two years; Dr. S. K. Chakravarty was elected vice-president in the vacancy created by the retirement of Sri V. Cadambe; Prof. B. R. Seth was re-elected secretary-treasurer for the next three years; and Dr. Jai Kishan, Prof. B. Sen Gupta and Prof. D. Banerjee were elected new members of the Executive Committee. The Executive Committee accepted the invitation of the University of Roorkee to hold the fifth Congress in Roorkee in December 1959.

The Emissivity of the Earth's Surface

Loss of heat by radiation from the Earth's surface is one of the fundamental physical factors of meteorology. J. T. Houghton (*Quart. J. Roy. Meteor. Soc.*, 84, 448; 1958) describes measurements with airborne radiometers at night which permit a comparison to be made between the temperature of the Earth's surface and the black-body temperature of the radiating surface computed from the upward flux of radiation at 200 ft. and the temperature and humidity of the intervening atmosphere. At this height about 60 per cent of the upward radiation comes directly from the surface. The observations gave a black-body temperature between the screen temperature and the ground temperature. Thus on one occasion over north-east Hampshire the effective black-body temperature was 3·2° C., whereas the screen temperature was 4·7° C. and the ground temperature 2·7° C. It appears that heath and arable lands radiate as black-bodies with an emissivity of 100 per cent. One observation over the English Channel, however, gave an effective temperature about 2 deg. C. higher than the screen and sea temperatures observed nearby at the *Royal Sovereign* lightship. An observation made just above a layer of stratus cloud at 3,000 ft. gave an emissivity of 100 per cent for the cloud.

A Mongolian Earthquake

A VIOLENT earthquake occurred on December 4, 1957, in the region of the Gurvan Bogdo mountain chain belonging to the Gobi–Altai system. In January 1958 a joint Mongolian–Russian scientific expedition proceeded to this region, and a brief account of the findings is presented by N. A. Florensov (*Priroda*, 7, 73; 1958). The region affected by the earthquake is a belt some 270 km. in length containing a system of branching fault fractures, many of them marked by very long fault scarps. The earthquake greatly affected overground and underground waters and the relief of the country.

Powder Patterns of Ferroelectric Domains

FOR more than fifty years red lead and sulphur have been used for picking out differently charged portions of the surfaces of insulators. Recently, however, G. L. Pearson and W. L. Feldmann, of the Bell Telephone Laboratories. New York, have used these substances in suspension in hexane to pick out positively and negatively charged domains, respectively, on the surfaces of ferroelectrics. The suspensions are applied separately; one after the other has dried on the surface under investigation. The lead oxide may be replaced by a dispersion of a cross-linked polymer derived from polystyrene. It is also found that colloidal particles of barium titanate, which have a very high dielectric constant, are deposited at ferroelectric domain boundaries, and this technique has given new information concerning domain structures of a number of ferroelectrics.

Four Rare Indian Animals

UNTIL 1952 there was no agency in India directly concerned with the preservation of the country's wild life, and the Forest Departments of the various States were able to give only a limited measure of protection within certain of the reserved forests under their jurisdiction. In that year the setting up of the Indian Board for Wild Life to advise the Central Government in New Delhi was an important event in Nature conservation in India. It was followed within a short time by the constitution of State Wild Life Boards in nearly all the States of the Indian Union. Now several States also possess separate Wild Life Departments, within the Forest Department, concerned solely with the preservation of wild life. The creation of these Boards at Central and State levels has not been followed by any remarkable results, nor has there been any marked improvement in the general position of wild life over the whole country. But the publicity given in the Press and elsewhere has succeeded in focusing public attention on the need to protect the country's rare and vanishing species and on the desirability of maintaining and developing wild-life reserves. As a result, writes E. P. Gee (*Oryx*, 4, No. 2; 1958), the status to-day of the Indian rhinoceros, Indian lion, brow-antlered deer and Kashmir stag is more secure than it has been since the lowest recorded levels of these species.

Gordon Childe Memorial Fund

THE issue of *Man* of October, 1958, contains an appeal for a Gordon Childe Memorial Fund. Details have not yet been worked out and everything will depend, of course, on the amount of money available. Any friend or admirer of the late Prof. Gordon Childe can send a subscription, now, to the Secretary, University of London Institute of Archæology, 31–34 Gordon Square, London, W.C.1.

Ramsay Memorial Fellowships for Advanced Students of Chemistry

THE Trustees will consider in June applications for two Ramsay Memorial Fellowships for advanced students of chemistry. One of the Fellowships will be limited to candidates educated in Glasgow, who can apply to be considered for either Fellowship. The value of each Fellowship will be £600 per annum, to which may be added a grant for expenses of research not exceeding £100 per annum. The Fellowships will normally be tenable for two years. Full particulars can be obtained from the Joint Honorary Secretaries, Ramsay Memorial Fellowships Trust, University College, Gower Street, London, W.C.1. Completed application forms must be received not later than April 13.

Mond Nickel Fellowships

MOND NICKEL FELLOWSHIPS are intended to enable selected British graduates to obtain additional training and wider experience in industrial establishments, in Britain or abroad, so that, if they are afterwards employed in executive or administrative positions in the British metallurgical industries, they will be better qualified to appreciate the technological significance of research and to apply its results. It is also hoped that the training facilities provided will attract persons qualified in sciences other than metallurgy into the metallurgical field. Each Fellowship will occupy one full working year;

it is hoped to award five Fellowships each year of an approximate value of £900–£1,200 each. Further particulars and forms of application can be obtained from the Secretary, Mond Nickel Fellowships Committee, 4 Grosvenor Gardens, London, S.W.1. Completed forms must be returned not later than June 1, 1959.

The Creole Foundation Prize

THE Creole Foundation, created by the Creole Petroleum Corporation—which is affiliated to the Standard Oil Company of New Jersey, and operates in Venezuela—with the object of encouraging the development of university, technical and industrial education and of scientific research in general, is offering a prize to be known as the Creole Foundation Prize. This will consist of 10,000 U.S. dollars and a diploma to be awarded to the author or authors of a work, selected through a competition, on any aspect of Venezuela in the fields of the natural, physical or social sciences. The prize will be given every two years in Caracas, beginning on October 17, 1960, the anniversary date of the creation of the Foundation; travelling and living expenses to Caracas will also be paid. Works to be submitted for the competition, which may be of any length and must either be written in Spanish, English, French, German, Italian or Portuguese or be accompanied by an adequate summary in one of those languages, must be received before December 31 in the year immediately preceding that in which the prize is to be awarded, at Premio Fundacion Creole, Apartado 889, Caracas, Venezuela, from which further information can be obtained.

University News: London

THE title of professor of physiology in the University of London has been conferred on Dr. J. A. B. Gray in respect of his post at University College. The title of reader in physics in the University has been conferred on Dr. R. L. F. Boyd in respect of his post at University College; and that of reader in political economy in the University has been conferred on Mr. W. J. Corlett in respect of his post at University College. Dr. M. J. Seaton, lecturer at University College, has been appointed to the University readership in physics tenable at that College.

Announcements

SIR GEORGE R. EDWARDS, managing director of Vickers-Armstrongs (Aircraft), Ltd., and immediate past president of the Royal Aeronautical Society, has been made an Honorary Fellow of the American Institute of the Aeronautical Sciences. Dr. A. M. Ballantyne, secretary of the Royal Aeronautical Society, has been elected a Fellow of the Institute of the Aeronautical Sciences.

THE Swiney Prize of the Royal Society of Arts for the best published work on medical jurisprudence has been awarded to Dr. Keith Simpson, reader in forensic medicine to the University of London at Guy's Hospital Medical School, for his book, "Forensic Medicine" (third edition). The Prize, which consists of £100 and a silver cup of the same value, is awarded on every fifth anniversary of Dr. George Swiney's death in 1844 for the best published work alternately on medical and general jurisprudence. The award is made by a joint committee of the Royal Society of Arts and the Royal College of Physicians.

ON his resignation from the post of assistant secretary of the Royal Meteorological Society, Mr. M. E. Shoenberg has been made a life-member of the Society. His successor at the Society is Mr. R. H. Levinson.

PROF. A. N. DUCKHAM has been appointed chairman of the Milk and Milk Products Technical Advisory Committee of the Ministry of Agriculture, Fisheries and Food in succession to Prof. H. D. Kay.

GRIFFIN AND GEORGE (RESEARCH AND DEVELOPMENT), LTD., has been formed by the Griffin and George Group to conduct research into, and the development of, new and improved scientific instruments and apparatus for laboratory use and process control. Dr. A. J. P. Martin, well known for his work on partition chromatography, acknowledged by the award in 1952 of the Nobel Prize for chemistry (jointly with Dr. R. Synge), has been appointed research director.

THE Ergonomics Research Society is holding a symposium on "Ergonomics: its Place in Industry" in Oxford during April 6–9. The symposium is intended to provide an opportunity for reviewing progress in the field of ergonomics research and application and for considering future developments in this field. Further information can be obtained from Dr. S. Griew, Department of Psychology, 22 Berkeley Square, Bristol 2.

THE Institute of Physics is arranging a one-day symposium entitled "Current Developments in the Production of High Vacua", to be held in London on April 17. There will be three sessions devoted to chemical and ionic pumping in kinetic vacuum systems; problems in the production of high vacua in large equipment; and analysis of residual gases in kinetic vacuum systems. Abstracts (but not preprints) will be circulated before the symposium, the proceedings of which will not be published in full. All inquiries should be addressed to the Secretary, Institute of Physics, 47 Belgrave Square, London, S.W.1.

THE University of Liverpool is arranging a special Conference on Mathematics, to be held at Derby Hall, Liverpool, during April 5–11. The Conference is intended to provide an opportunity for teachers of mathematics in grammar schools, technical colleges and universities to meet mathematicians employed in industry, government establishments and research organizations, and learn something at first hand of mathematics in action. Prof. Louis Rosenhead will be chairman of the Conference, which will be mainly residential, but arrangements are being made to enable local teachers to attend on a non-residential basis. Inquiries should be addressed to the Director of Extra-Mural Studies, The University, Liverpool.

THE Proceedings of the International Congress on Radiation Research, held in Burlington, Vermont, during August 11–15, will soon be published by the Academic Press, Inc. The volume will be Supplement 1 of the journal *Radiation Research*, and has been edited by Douglas E. Smith, Argonne National Laboratory, Lemont, Illinois.

ERRATUM. In the communication entitled "Population Differentiation within Plant Species in Response to Soil Factors" in *Nature* of January 10, p. 129, the names against the curves in Fig. 1 should be interchanged.

PLANT PHYSIOLOGY IN CZECHOSLOVAKIA

By Prof. WALTER STILES, F.R.S.

AT the invitation, and as the guest, of the Czechoslovak Academy of Sciences, I recently had the opportunity of visiting a number of plant physiological research establishments in Czechoslovakia. Since, so far as I know, few if any British plant physiologists have visited these institutions during the past twenty years, a brief impression of them may be of interest to Western readers.

In Prague, plant physiological research is carried out in two institutions, the Charles University and the Biological Institute of the Academy of Sciences. As most readers will know, the Charles University is one of the oldest in Europe, having been founded in the year 1348. For a time, in the latter part of the nineteenth and first part of the twentieth centuries, there were two universities in Prague, a Czech and a German, but since the War no such division of university administration any longer exists. The plant physiological department of the University, under the direction of Prof. S. Prát, is housed in the buildings of what was formerly the German University, which will be associated in the minds of older botanists with such well-known names as Molisch and Czapek. It is perhaps less well known that Sachs, who with reason has been regarded as the founder of modern plant physiology, worked for a time in Prague. These buildings are now sixty years old, but are spacious and well equipped, and the fine library with its large collection of pamphlets happily survived the German occupation although, unfortunately, the index of these was destroyed. Here much research is in progress under Prof. Prát's direction, as is indicated by the considerable body of publications which have appeared from his department during the past twelve years. Of work being carried out at present, particular attention is being given to the absorption of humic substances and their influence on plant metabolic processes. As botanists in Britain will know, a large collection of pure cultures of algae was made in Prague by Prof. E. G. Pringsheim and a collection of them was instituted in Cambridge during his residence there. Although many of his original cultures were lost to Prague after his departure from that city, others have been added and there is now maintained in the plant physiological department of the Charles University a large collection of cultures, not only of algae, including Cyanophyceae, but also of liverworts and mosses.

In the chair at the Charles University, Prof. Prát succeeded Prof. B. Němec, whose plant physiological researches in many fields won him a world-wide reputation half a century ago. It was a particular pleasure to me again to meet Prof. Němec and to be able to report to the many admirers of his work that in his eighty-sixth year he is hale and hearty and alert. To commemorate his eighty-fifth birthday in March 1958 a memorial volume entitled "Studies in Plant Physiology" was produced by the Czechoslovak Academy of Sciences and in which twenty-four distinguished botanists from many countries, including the United States, France, Holland, West Germany and Yugoslavia, as well as Central and Eastern European countries, contributed. It is interesting to note that among those paying tribute to Prof. Němec in this way was another veteran plant physiologist, Prof. W. J. V. Osterhout.

The Institute of Biology of the Czechoslovak Academy of Sciences has been so called since 1952, when the Academy was constituted; actually the building dates from 1926, having originally been devoted to research in agronomy and phytopathology. During 1950–52 it housed the Central Institute of Biology and Central Institute of Chemistry. The Institute is under the direct auspices of the Academy and is a purely research institution under the direction of Dr. I. Málek. Not only plant physiology but other experimental aspects of biology are dealt with here; these include microbiology, phytopathology, parasitology, radiobiology and electron microscopy among others. About a hundred research workers are engaged in investigations in the Institute. Among research projects of interest to plant physiologists are investigations on the relations between osmotic value and water deficit, cytochemical researches on mitochondria and their relation to plastids, and bud development in relation to the season of maturity and biennial bearing. Although the present buildings impress one as modern and very well equipped, new buildings for the purpose of biological research are being built.

In Brno, plant physiological work is in progress in two institutions, the laboratory for plant physiology and anatomy of the University and the Botanical Institute of the Technical University. In the former, under the direction of Prof. V. Rypáček, several researches of interest to plant physiologists are in progress. Among these may be mentioned the investigation of the growth and action of a number of wood-destroying fungi, including their effect on the composition of the attacked wood, the action of humic acid on the growth of plants, and the effect of one plant on another, with particular reference to the influence of couch grass on wheat, an effect which appears to be very striking. In the Technical University, Prof. R. Dostál, whose first work on correlation was published fifty years ago, many years before the word auxin had even been thought of, is still working enthusiastically on problems of correlation. Here, in the city where Mendel lived and worked, I was pleased to visit the little monastery garden where he carried out his pioneer experiments. In the garden is a stone with an inscription in Czech, German and French recording the fact that here Mendel carried out his experiments.

In Bratislava, the capital of Slovakia, scientific interests are in the care of the Slovak Academy of Sciences, while at the Comenius University plant physiology is in the charge of Prof. L. Pastýrik. The plant physiological laboratory here dates from 1936, and it is interesting to note that it was at first under the direction of Prof. B. Němec. Here a main plant physiological interest is in the mineral nutrition of plants. Thus, work has recently been published on the movement and accumulation of mineral nutrients in the xylem and phloem of apple and pear trees and on the dependence of the metabolism of tobacco leaves on micro-nutrients.

The site has been cleared in Bratislava for a new institute which will house plant physiology. If this is equal in quality to the fine Institute of Biochemistry maintained by the Slovak Academy of Sciences, plant physiology will be well provided for in the capital of Slovakia.

The time at my disposal did not permit me to visit Košice in the south-east of Slovakia ; but I was given to understand that work of high quality on photosynthesis was in progress there.

Archæology, although outside my range of special knowledge, is within my field of general interests, and I was therefore pleased to visit the Archæological Institute of the Slovak Academy of Sciences at Nitra. This is appropriately housed in Nitra Castle and is provided with a fine library and laboratories well equipped on modern lines.

I cannot conclude this brief account of my impressions of plant physiological activities in Czechoslovakia without expressing my indebtedness to the Czechoslovak Academy of Sciences and the Slovak Academy of Sciences for the excellent arrangements made for my visits to the various research institutions and of my deep appreciation of the friendliness and kindness I experienced from everyone I met in Czechoslovakia and particularly from my plant physiological colleagues in Prague, Brno and Bratislava and from the director and staff of the Archæological Institute in Nitra.

SELF-REGULATION IN LIVING SYSTEMS

SYMPOSIUM AT OTTAWA

A SHORT symposium on self-regulation in living systems, organized by Dr. D. K. C. MacDonald, was held at the laboratories of the National Research Council in Ottawa on October 20. About twenty-five representatives of a wide range of professions—biophysics, electrical engineering, mathematics, neurology, philosophy, physics, psychology and zoology—took part in the symposium and an attempt was made to establish some common ground within these fields through problems of interest to all. This first meeting was necessarily of an exploratory nature.

The problem of self-regulation in living systems may be considered on two levels. First, the details of self-regulation within a given animal (homeostasis) and its perception of and reaction to the external world, both of these tasks being handled by the nervous system. This might be termed the microscopic picture. Second, there is the relation of animal populations with their surroundings (ecology)—or the macroscopic level. In both cases the processes involved are analogous to those found in the inanimate control systems of physics and engineering.

Papers outlining our knowledge of the nervous system were read by Dr. B. Delisle Burns and Dr. P. M. Milner, both of McGill University, and by Dr. E. A. Atack (Ottawa). A nerve cell, or neurone, when stimulated sufficiently, will transmit the signal to other neurones which are connected to it. This period of activity is followed by a refractory period, or 'dead-time', and thus the mode of action is analogous to a Geiger counter tube. In the control centres of an animal the neurones appear to be connected together in an unorganized fashion (a useful genetic property) to form a 'nerve net'. A mathematical treatment of the propagation of signals within such nets has been given by Beurle (1956). Nerve nets in the lower control centres are responsible for self-sustaining processes within the body. For example, the control of respiration is due to nets located within the brain stem. The processes of learning and memory appear to be associated with the nerve nets located in the cerebral cortex or outer layer of the brain. It is supposed that repeated applications of the same stimulus produce some change in the neurones affected by it (or in their connexions), and thus pathways within the nets become established. Similarly, an association of pathways may be built up. Thus memory seems to be due to combinations of neurones. Since, in man, there are about 10^{10} neurones involved the total possibilities are obviously enormous—in marked contrast to insects (where the relevant number is of the order 10^3) which nevertheless show an apparently complex behaviour. Cerebral malfunctioning may affect the internal workings of the body or show external effects. Thus analysis of pathological symptoms will suggest the site of a particular disturbance.

A particular aspect of the nervous system, the handling of visual information, can be readily demonstrated. Dr. A. Burton (University of Western Ontario) presented some rather sophisticated optical illusions exhibiting : (1) a biochemical cycle in the retina, (2) adaptation in the cerebral cortex, and (3) the subjective nature of much visual information.

There was, inevitably, a discussion on the relation of computing machines to the brain, initiated by Dr. D. K. C. MacDonald (National Research Council). The ability of present-day computors to make decisions involving some long-term strategy was emphasized. It was suggested in the discussion that a distinction between an animal and a machine could be made in terms of the responses of an animal at 'higher' levels (for example, pleasure, pain) and by the fact that an animal does not always appear to behave logically.

Some large-scale aspects of self-regulation were summarized by Dr. Max Dunbar (McGill University). Particular ecological systems were discussed and it was concluded that a non-oscillatory state provides optimum conditions for survival. (Indeed, violent oscillations may prove lethal to a particular species.) Some animals contribute to stable conditions by relatively inefficient breeding habits and by tendencies or conditions leading to a high death-rate. Relations between population-levels of various species are often analogous to feedback system characteristics. It seems, therefore, that ecological systems may show an apparent ability to 'learn'. Of interest here is J. Z. Young's description of the brain as an ecology of nerve cells.

The freely ranging discussion provoked by all the papers indicated that the gaps between the various disciplines had certainly been narrowed. It is hoped that a further symposium on a similar topic will be organized in the near future. An informal report of this symposium is in preparation. DOUGLAS L. MARTIN

THE INDIAN AGRICULTURAL RESEARCH INSTITUTE

THE Indian Agricultural Research Institute has been accorded the status of a university with power to confer the degrees of M.Sc. and Ph.D. in all the important aspects of agricultural science. The new Postgraduate School was formally inaugurated on October 6, 1958, by Shri Ajit Prasad Jain, Minister for Food and Agriculture in the Government of India.

The Institute is popularly known as the Pusa Institute, after a small village called Pusa in Bihar, where it was first established as the Imperial Agricultural Institute in 1905 with a gift of £30,000 from Mr. Henry Phipps, an American philanthropist. It has now developed into a centre of considerable size, providing facilities for training and research in almost all the important branches of agricultural science. These various activities are carried out by its seven Divisions, covering, respectively, agronomy, botany, mycology and plant pathology, entomology, horticulture, soil science and agricultural chemistry, and agricultural engineering, under the over-all supervision of the director, Dr. B. P. Pal. All the Divisions are housed separately in spacious buildings, furnished with modern equipment, and each is staffed with teachers and specialists in the appropriate field.

The Institute has inherited a great tradition of agricultural research and education, going back to the work of Leather in agricultural chemistry, of Butler on fungi and fungal diseases of plants, of Maxwell-Lefroy and Fletcher in cataloguing and combating insect pests, of the Howards in breeding the early 'Pusa' wheats, and of Venkataraman in breeding Coimbatore canes. High among the recent achievements are the breeding of *NP* ('New Pusa') wheats, of which *NP* 710 and *NP* 718 combine considerable resistance to rust with high resistance to loose smut. An outstanding success is the breeding of *NP* 809 wheat for the hills, uniting resistance to the three rusts. Among other contributions of note are the building up of a fine milch herd of the Sahiwal breed; the construction of schedules for the control of some important diseases of sugar cane; and the improvement of techniques of breeding parasites for the biological control of some insect pests of crop plants.

The Library, which receives more than a thousand periodicals and possesses almost all the important publications on agricultural science, is considered to be the best agricultural library in the East, and caters for the needs of agricultural scientists all over India. Other assets of the Institute include collections of varieties of crop plants from which the plant breeder can select the genes for his breeding work; the National Collection of Insects; the Herbarium Cryptogramme Indiae Orientalis, one of the best assemblages of fungi in the East; and the Indian Type Culture Collection.

The archives of the Institute show that, from its inception in 1905, it was meant to be a central organization of postgraduate teaching. In 1923, two-year postgraduate courses leading to the award of the diploma of the associateship of the Imperial Agricultural Research Institute were instituted, offering limited facilities to students in specialized fields, without, however, offering any definite courses. In 1945 the system of training was thoroughly reorganized, courses and syllabuses were prescribed and a system of examinations introduced. The diploma awarded is comparable with the M.Sc. degree of a university.

The present decision to provide the Institute with a Postgraduate School is a natural step in fulfilling the objects which the planners of the Institute had in view. The recommendations of the Indo-American team on agricultural research and education were instrumental in giving shape to the ideals of its founders. The Postgraduate School, which will mainly be responsible for carrying out the teaching programme, has come into existence with the generous aid of the Rockefeller Foundation. The aim is to train leaders for the programme to improve agricultural technology in India.

The students will have a large number of courses to choose from, including crop husbandry, soil and water management, agricultural extension; plant breeding and genetics, cytogenetics and plant physiology; taxonomy, ecology, toxicology, parasitology, and physiology of insects; pomology, olericulture, fruit and vegetable preservation; mycology and plant pathology; soil science and agricultural chemistry; and agricultural engineering. Courses in experimental statistics will be offered in co-operation with the Indian Council of Agricultural Research.

Provision has been made, for the present, for admitting each year up to one hundred students for the M.Sc. degree and fifty students for the Ph.D. degree.

B. P. PAL

THE EMPLOYEE'S POINT OF VIEW

IN the middle nineteen-thirties, the National Institute of Industrial Psychology was asked by a large and well-known company to help in solving a staffing problem. The company's employment policy was progressive, and reasons for a very high rate of leaving were obscure. It was arranged to take the (then) unorthodox step of inviting employees to come, in confidence, to the Institute's investigator to give suggestions for improvements in their working conditions or to mention features of them which they would like to see changed. These interviews had far-reaching results; from their success stems a technique which has been fruitfully applied in the United Kingdom to the diagnosis of many working situations, in industry, shops and offices, hospitals and voluntary organizations. It brings to the study of people in their working environment, and particularly in relation to difficulties they experience, a special combination of human understanding with scientific discipline.

The core of the method consists in confidential, undirected interviews with a sample of employees of all levels; the interviews are conducted by an impartial investigator who is not on the staff of the organization, and in whose freedom from bias all concerned may have confidence.

After many years of experience, during which the Institute's technique in this work was progressively improved, there was developed a standard system for classifying subjects raised in such interviews. It provided convenient, ordered categories to which could be assigned remarks relating to any aspect of working life, and it was intended to facilitate future study of the accumulating material.

Dr. Isabel Blain has now made a pilot study of results collected and reported by these methods within a recent two-year period (Comments on the Job. Nat. Inst. Indust. Psych., Rep. 13, 1958). The data came from six firms ; all were manufacturing companies, and apparently had little in common save their concern over some aspect of their organization or operation, to improve which they had invited the Institute's help. They differed in size of pay-roll, form of ownership, geographical position, age, history and tradition, arrangements of hours and shifts, degree of trades union influence, amenities, welfare provisions, and physical working conditions. The purpose of the study was to see whether, in spite of these differences, similarities would be found in the spontaneous remarks made by 1,678 factory staff and operatives.

Some of the salient points which emerged showed a surprising degree of similarity in each of the firms investigated. Thus, planning and control procedures, timing, time standards and time allowances, maintenance and stores arrangements were common topics of complaint.

Practice and policy relating to training, promotion and transfer were criticized, sometimes through ignorance, sometimes justifiably, due to acknowledged defects ; but there were also instances where approval was expressed of company action in these fields.

On matters of pay, men complained more frequently than women about the amounts earned ; but the greatest body of critical comment related to financial incentive schemes and to differentials.

In every company there were remarks about the inadequate definition of responsibility and authority ; similarly, poor liaison between shifts or between departments was commonly mentioned ; there were also frequent complaints about lack of information from management.

PATTERN OF SYNTHESIS OF DEOXYRIBONUCLEIC ACID IN *BACILLUS CEREUS* GROWING SYNCHRONOUSLY OUT OF SPORES

By DR. I. ELIZABETH YOUNG and PROF. PHILIP C. FITZ-JAMES

Department of Bacteriology and Immunology and Department of Biochemistry, University of Western Ontario

VARYING degrees of synchrony of bacterial cell division have been achieved by prior subjection of the cell population to chilling[1], cycles of chilling and warming[2–5], to starvation followed by replenishment[6,7] and by separation of the cells into a homogeneous group by fractional filtration[8]. In all such cases synchrony "is initiated by a phase of recovery from imposed stress and unbalance"[6] and in some there is evidence that interference with the synthesis of deoxyribonucleic acid is the critical feature[9]. It has already been shown that the initial duplication of the chromatin body of synchronously germinated spores (*B. megaterium* and *B. cereus*) is accompanied by a linear synthesis of deoxyribonucleic acid[10]. But, as no cellular division occurred prior to these doublings, no data were available regarding the relationship between synthesis of deoxyribonucleic acid and the normal division cycle. Such has now been obtained from a combined cytological and chemical study of *B. cereus* in which synchronous germination of spores was followed by two successive periods of synchronous cell division.

Uniform batches of spores were harvested from either the agar medium of Howie and Cruickshank[11] or a fluid medium (glutamine–casein–yeast) developed for the study of synchronous spore formation[12]. Spores were washed free of all traces of cell debris by eight cycles of differential centrifugation from water. Spore counts were made on appropriate dilutions of the final clean suspension.

The germination medium used was similar to that already described[10]. Spores sufficient to give a final concentration of $0{\cdot}6 \times 10^9$/ml. were inoculated below the surface of the medium, which had been warmed to 37° C. Aeration by shaking was begun immediately, and after 3 min. a drop of tri-*n*-butyl citrate was added to counteract foaming.

Cells centrifuged from rapidly chilled samples were washed in quick succession with ice-cold bicarbonate buffer, 50 per cent ethanol in buffer and absolute ethanol. Following disruption of the cells with glass beads (Ballotini No. 12) in the Mickle[13] tissue disintegrator, deoxyribonucleic acid was extracted by the Schmidt and Thannhauser procedure[14] and estimated by the Dische reaction[15]. At each time period of analysis, the living cells were examined in the phase-contrast microscope and osmium-fixed impression smears stained by an azure *A*–Feulgen procedure[16] were examined under the light microscope.

In order to obtain good synchrony through the first two divisions of the emergent cells, it was considered necessary that 95 per cent of the spores lose refractility and stain deeply with crystal violet (that is, begin germination) during a 1-min. interval commencing 1½–2 min. following inoculation. Occasionally this degree of synchrony could be obtained with fresh spores. In such cases prior activation with sublethal heating[17] (70° C. for 15 min.) did not improve the degree of synchrony. However, heat treatment usually decreased the response time of germination and made synchrony more readily attainable. It should be stressed that the subsequent pattern of synthesis of deoxyribonucleic acid was the same whether or not the spores were activated by heat.

In Fig. 1, the content of deoxyribonucleic acid of a culture is plotted as a function of the initial number of spores from resting spores (zero time) to the end of the second division of the emergent cells. The rise associated with the initial duplication of the spore chromatin body (Fig. 1, up to 60 min.) has been described earlier[10]. In three separate experiments, no alteration in the rate of synthesis of deoxyribonucleic acid followed this initial doubling of the acid and duplication of the nuclear body. It could be seen from the nuclear-stained preparations and from the phase-contrast appearance of the living cells that the first cell division began about 72 min. after inoculation (Fig. 2) and was complete some 6–8 min. later. Direct cell counts at these times confirmed these observations.

At the beginning of division, each cell contained $2\frac{3}{4}$ times the average amount of deoxyribonucleic acid found in the original spore. At the end of division this had risen to 3 times, so that each new cell now contained $1\frac{1}{2}$ times the spore amount of deoxyribonucleic acid. After division, synthesis again continued in a linear fashion but at a slightly greater rate than before, until each new cell once more entered division with $2\frac{3}{4}$ times the spore-level of deoxyribonucleic acid (Figs. 1 and 2). Duplication and separation of the nuclear bodies thus occur midway between cell divisions and during a period of continuing synthesis of deoxyribonucleic acid (Fig. 2).

Since the deoxyribonucleic acid content of a *Bacillus* cell may vary from 1·5 to 2·8 times the spore-level, the 'average' cell in an asynchronous population would contain approximately twice the spore amount of deoxyribonucleic acid[12,18]. Furthermore, the average amount of acid per spore has been found to be remarkably constant for any given species and not altered by variations in the composition of the growth medium[19].

A slight decrease in synthesis of deoxyribonucleic acid during the period of cell division is indicated by the results obtained from samples taken at 10-min. intervals (Fig. 1). The slope of the rise of deoxyribonucleic acid before the first division is 1·4, while after the division it is 1·8 (Fig. 1). A more pronounced decline in the rate of synthesis of deoxyribonucleic acid was encountered during the second division when another sampling, 5 min. after the 100 min., was possible.

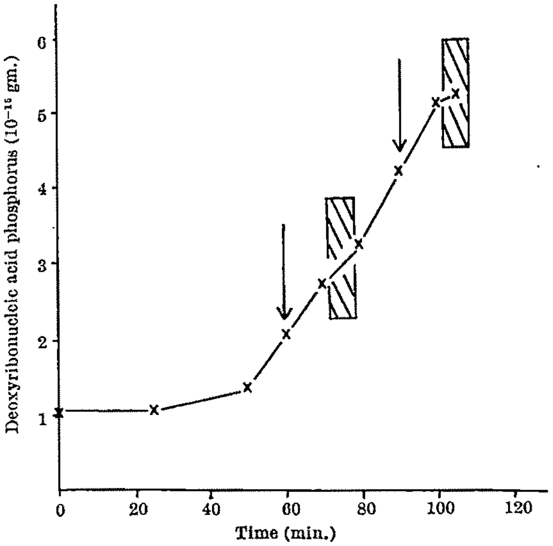

Fig. 1. Deoxyribonucleic acid-phosphorus expressed on the basis of the initial spore count, during the synchronous growth of *B. cereus* from spores through two cell divisions (hatched areas). The arrows indicate the period when each cell contained two fully separated chromatin bodies and twice the spore content of deoxyribonucleic acid

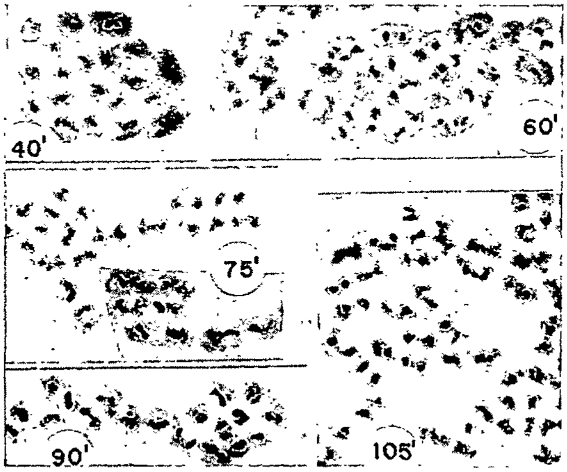

Fig. 2. Changes in nuclear morphology during synchronous growth of *B. cereus* out of germinated spores. Osmium-fixed smears, azure *A*–Feulgen. By 40 min. the spore coats still cover the growing cells but the single nuclear bodies have begun to elongate. At 60 min. the deoxyribonucleic acid has doubled and each cell in proper focus shows two separated nuclear bodies; shed spore coats are also present. By 75 min. the first cell division is proceeding and each nuclear structure is growing into two again. By 90 min. each daughter cell once more contains two separated nuclear bodies, and by 105 min. the second division is under way with the nuclear bodies partly separated like those at 75 min. (× *c.* 2,700)

Cohen's[7] studies with a thymine-requiring *E. coli* synchronized by starvation and replenishment of thymine suggested that doubling of the deoxyribonucleic acid occurred prior to cell division and that during division synthesis of the acid ceased. Lark and Maaløe[2] found that in heat-treated cultures of *S. typhimurium* doubling of the acid was followed by nuclear division. However, in contrast to the findings of Cohen[7], cell division overlapped the period of synthesis of deoxyribonucleic acid. The results reported here, in which synchrony is achieved without recourse to artificial treatment, indicate that during the growth-cycle, synthesis of deoxyribonucleic acid is continuous between, but diminished in rate during, cell division.

The work was supported by a grant from the National Research Council of Canada.

THE MYOGLOBIN MOLECULE

By DR. HELEN SCOULOUDI

Davy Faraday Research Laboratory, Royal Institution, London, W.1

KENDREW and others[1] have listed a number of forms of myoglobin crystals from aquatic animals, which have a large proportion of this protein in their muscles. These crystalline forms were studied by the methods of X-ray analysis. In a recent paper[2], a three-dimensional solution of the molecular form of myoglobin in type *A* crystals from sperm-whale to a resolution of 6 A. is described. The X-ray analysis provides a map of the electron density in the crystal, and continuous chains of high density can be traced which presumably represent coiled-up polypeptide chains, probably one to each molecule. A disk-shaped region of especially high density is identified with the haem group. The molecules so outlined are separated by extended regions of uniform density which must be attributed to the liquid in the intermolecular spaces. This form of the convoluted chain is illustrated in Fig. 2 of Kendrew's paper[2].

I have been engaged on an X-ray study of myoglobin from the common seal (*Phoca vitulina*), first characterized by Kendrew and others[1] as type *C*. This forms monoclinic crystals, space group $A2$, $a = 57\cdot9$ A., $b = 29\cdot6$ A., $c = 106\cdot4$ A., $\beta = 102°\ 15'$, with four molecules per unit cell. The method of isomorphous replacement introduced by Perutz[3] has been used, the attached heavy-atom groups being $AuCl_4'$, HgI_4'' and *p* - chloro - mercuri - benzene sulphonate. These groups were introduced by methods analogous to those used by Kendrew and others[2] in type *A*. A two-dimensional projection of the crystal density on the *b*-plane has been obtained to a resolution of 4 A., and is shown in Fig. 1.

The present communication describes an attempt to explain Fig. 1 in terms of Kendrew's three-dimensional model. If the myoglobin molecule from sperm-whale is closely similar to the myoglobin molecule from seal, it should be possible to take the sperm-whale myoglobin molecule, re-orientate it in a suitable way, project its density on to a plane, and obtain a match with the density map of Fig. 1. Allowance must, of course, be made for the overlap of neighbouring molecules. As will be shown, it is possible to make this comparison and the fit is remarkably good.

I have been guided in making the comparison by two features of the molecule. In the first place, the Fourier map in Fig. 1 shows regions of high density marked *H*, and there is a strong *a priori* probability that these are the haem groups. In the second place, the results of Ingram and others[4], based on electron spin resonance methods, indicate the orientations of the normals to the haem groups in both the sperm-whale and seal myoglobin crystals. In searching for the right direction in which to make the projection, one therefore has a fixed point in both molecules, the haem group, and these must be brought into superposition. The normals to these haem groups must also be brought into alignment, so that the only variable left is the angle through which the molecule must be turned around the haem-group normal.

A first approximation to the correct orientation was made with the help of a solid model like that shown in the paper by Kendrew *et al.*[2]. Several orientations for the model were tried and in each case the total

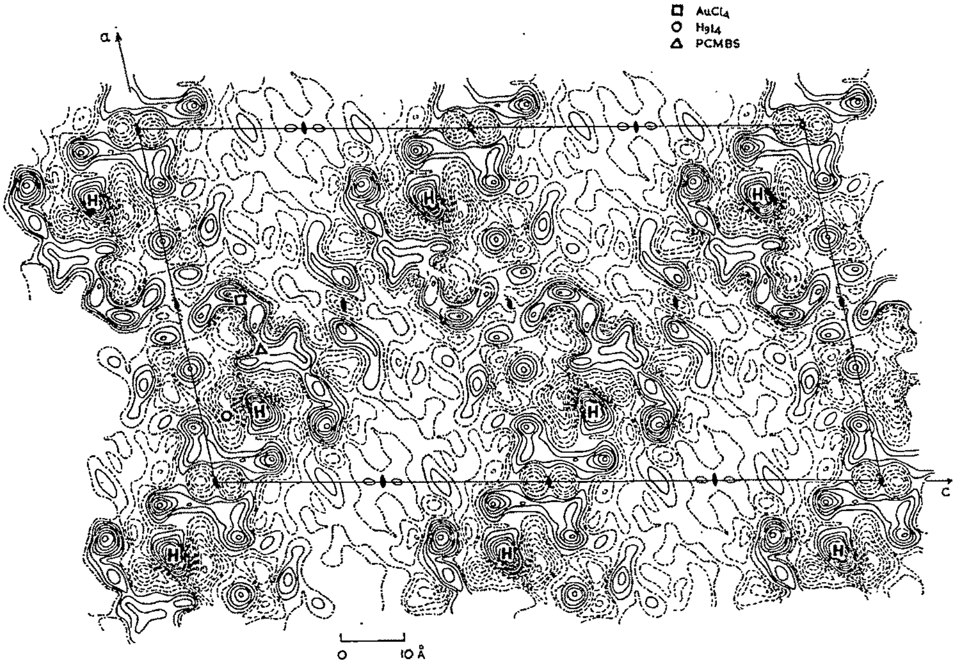

Fig. 1. Projection on the *b*-plane of the electron density distribution in the cell of seal myoglobin, seen at a resolution of 4 A. □, $AuCl_4$; ○, HgI_4; △, *p*-chloro-mercuri-benzene sulphonate

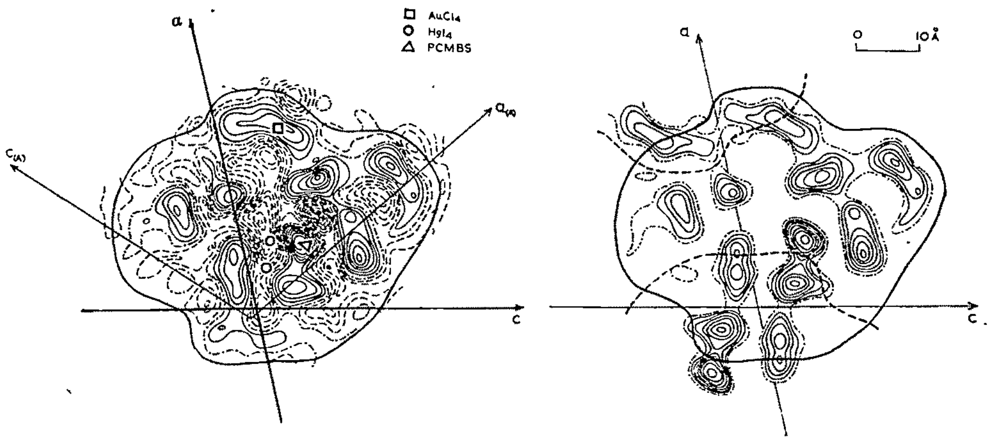

(a) (b)

Fig. 2. (*a*) Single molecule of sperm-whale myoglobin projected on to the *b*-plane of seal myoglobin ; (*b*) the projected molecule with overlap from the molecules related by the screw axes

thickness of chain as shown in that figure was projected on to a plane. When a promising approximate match to Fig. 1 was obtained, it was further explored by summing up the actual electron densities in the appropriate direction. A detailed description will appear elsewhere.

Fig. 2 (*a*) shows this summation for a single molecule projected in a direction which was found to give the best agreement. The axes of the seal myoglobin crystal are shown as heavy lines, the projected axes of the sperm-whale myoglobin crystal as light lines. In the cell of the seal myoglobin crystals there are screw axes at $a = 0$, $c = 0$; $a = \frac{1}{2}$, $c = 0$; $a = 0$, $c = \frac{1}{2}$, $a = \frac{1}{2}$, $c = \frac{1}{2}$; so to compare the results one must allow for the fact that two molecules, related by a screw axis, will overlap. The superposition is shown in Fig. 2 (*b*), where for simplicity contours of positive density have alone been drawn, and the outline of the molecule as deduced by Kendrew is indicated. Fig. 3 is another version of Fig. 1, the *b*-axis projection of seal myoglobin. In this version, only terms to a resolution of 6 A. have been included, and only positive contours drawn, so as to make the comparison with Kendrew's results more direct.

The correspondence is remarkably close, as will be seen by comparing Fig. 2 (*b*) and Fig. 3. The outlines of the molecules are drawn to facilitate the comparison. All the high-density features obtained by projecting Kendrew's solution are faithfully reproduced in the *b*-projection of the seal myoglobin crystal. The haem groups, seen edgewise in the projection, appear as dense regions in corresponding places. Further, the Au and HgI_4 group used in both analyses lie in corresponding positions in the two projections, Fig. 2 (*a*) and Fig. 1, indicating that they are attached to the protein molecules at the same points. (This is not true, however, of *p*-chloromercuri-benzene sulphonate, but there is some

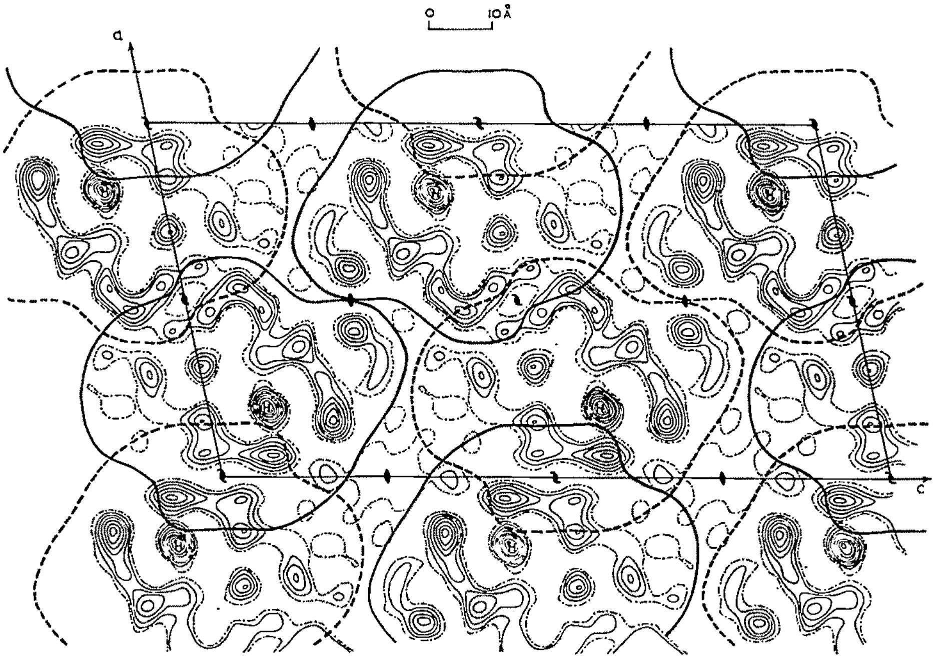

Fig. 3. Electron density projection of seal myoglobin seen at a resolution of 6 A.

evidence that this group is retained in the lattice interstitially, so that its position depends on the molecular packing and is, therefore, different in different forms.)

This correspondence would appear to prove: (*a*) that the two-dimensional Fourier projection of Fig. 1 is nearly correct; (*b*) that the myoglobin molecules in two different species, seal and sperm-whale, are closely similar in general configuration even though their amino-acid compositions are known to differ in details; (*c*) that the outline of the molecule deduced by Kendrew is very nearly right, because there could not be so close a fit if it had been incorrectly traced and included portions of neighbouring molecules.

I wish to thank Sir Lawrence Bragg for his continuous interest and encouragement; Dr. J. C. Kendrew for allowing me to use his results and for his advice throughout this work; Dr. D. C. Phillips for much help and discussions; and Dr. V. C. Shore for assistance with some of the calculations. I am indebted to the Mathematical Laboratory, University of Cambridge, for computing facilities on the EDSAC.

EFFECTS OF GAMMA-RADIATION ON SOME CARBOHYDRATES, HYDROXYACIDS AND AMINO-ACIDS IN AQUEOUS SOLUTIONS

By DR. S. A. BARKER, DR. P. M. GRANT, PROF. M. STACEY, F.R.S., and DR. R. B. WARD
Department of Chemistry, University of Birmingham

IN an investigation of the effect of γ-radiation from a 200-c. cobalt-60 source on dilute (0·1 per cent) aqueous solutions of some carbohydrates, hydroxyacids and amino-acids we have found that in the absence of oxygen (that is, *in vacuo* or under nitrogen), radicals[1] derived from these compounds exhibit a strong tendency to dimerize (irradiation dose $5·5 \times 10^{19}$ eV. ml.$^{-1}$) and that prolonged irradiation produces polymeric materials. Acidic non-dialysable polymers have been isolated (see Table 1), which

Table 1. IRRADIATION OF CARBOHYDRATES, HYDROXY- AND AMINO-ACIDS IN AQUEOUS SOLUTION

Solute irradiated	Conditions	Polymer formation indicated by dialysis	Polymer formation indicated by cetavlon	Other compounds formed, remarks, etc.	Periodic acid treatment (see text)
Maltose	Vacuum	Yes	Yes	Glucose, gluconic acid, maltobionic acid, *et al.*	
Glucose	Vacuum	Yes	Yes	Gluconic acid, 2-oxo-D-arabino-aldohexose, 2-oxo-D-arabino-hexonic acid, arabinose, *et al.*	
	Oxygen	No	No	Gluconic acid, *et al.*	
	Nitrogen	Yes	Yes	As vacuum system	
Glycollic acid	Vacuum	Yes	Yes	Glyoxylic, tartaric, oxalic and formic acids, formaldehyde and CO_2	Yes
	Oxygen	No	No	As for vacuum system, but only traces of tartaric acid	
Glyoxylic acid	Vacuum	—	—	Oxalic acid, reducing acidic dimer and trimer. Dimer may be dihydroxytartaric acid	Yes
	Oxygen	—	—	Oxalic acid, no other non-volatile products detected	
Tartaric acid	Vacuum	—	—	Non-acidic reducing compound with $R_T = 1·6$, reducing material with $R_T = 1$. Main product had $R_T = 0·3$, $M_T = 1·0$ ('dimer' ?)	Yes
	Oxygen	—	—	Mesoxalic acid, glyoxylic acid, considerable reducing material with $R_T = 1$	Yes
Oxalic acid	Vacuum	—	—	Small amounts of a reducing compound formed, having $R_T = 0·6$	
	Oxygen	—	—	Considerable loss of oxalic acid, but no other non-volatile compounds detected	
Lactic acid	Vacuum	Yes	Yes	Not examined	
Gluconic acid	Vacuum	Yes	Yes	Arabinose, arabonic acid, *et al.*	
Mandelic acid	Vacuum	?	?	Heavy precipitation from aqueous solution, CO_2 formed. Precipitate contains C_6H_5. and .COOH groups	
Formic acid	Vacuum	—	—	Mesoxalic acid, dihydroxytartaric acid and probably tartaric acid. Streaking between $R_T = 0$ and $1·5$	Yes*
	Oxygen	—	—	No non-volatile products	
Glycerol	Vacuum	—	—	Glyceraldehyde, glyceric acid, at least two non-reducing compounds behaving as hexitols. Traces non-reducing acids	
Glycollic acid and glyoxylic acids†	Vacuum	—	—	Dihydroxytartaric acid. Slight uptake of bromine water, suggesting some dihydroxymaleic acid	
Glycollic† and tartaric acids	Vacuum	—	—	Glyoxylic acid, slightly reducing acidic component with $R_T = 0·7$, suggesting a 6-C co-dimer. Reducing compounds with $R_T = 1$.	
Glyoxylic† and tartaric acids	Vacuum	—	—	As for glycollic and tartaric acids system, but more reducing compounds at $R_T = 1$ and $0·7$	
Glycerol and glyceraldehyde†	Vacuum	—	—	Hexonic acids, small amounts of glyceric acid. Hexose production uncertain	
Glycerol and 1 : 3-dihydroxyacetone†	Vacuum	— —	—	As for glycerol and glyceraldehyde system. Ketohexose production doubtful	
Glycine	Vacuum	—	Yes	Compounds or compound with $R_{\text{glycine}} = 0·5$ detected with ninhydrin and alkaline silver nitrate	
	Oxygen	—	No	No compounds with $R_{\text{glycine}} < 1$	
Alanine	Vacuum	—	Yes	Not examined	
Phenylalanine	Vacuum	—	Yes	Not examined. No precipitation, but the freeze-dried solute was only sparingly (0·2 per cent) soluble in water (cf. mandelic acid)	

* Forms glyoxylic and oxalic acids.

† Indicates the component in mixed systems which was the more readily destroyed by radiation.

gave precipitates with 2 per cent 'Cetavlon' solution[2], the precipitates being soluble in M sodium chloride. The presence of oxygen drastically reduced dimerization, and no polymers were then detected. Instead, oxidation products were formed by processes which involved considerable C—C bond scission and decarboxylation. These effects can be readily explained by the radicals initially produced from the solvent causing hydrogen abstraction from the organic solute, thereby forming an organic radical[3]. *In vacuo* or under an atmosphere of nitrogen these radicals may join together or undergo saturation by the addition of a solvent radical. In the presence of oxygen, the gas readily adds on to the organic radical to yield a peroxy-radical, which may react with radicals[4] present in the system to yield a molecule in which, ultimately, a hydroxy group has been substituted on to the site of the original hydrogen abstraction.

The emphasis in this work has been on the radical addition reactions occurring *in vacuo*, including reactions occurring in solutions containing more than one solute when dimers are formed by linking of the various radicals. The glucose and glycollic acid systems have been examined, and in the latter case a complete mass balance in the presence and absence of oxygen has been obtained[1]. Polymeric materials have been isolated as indicated, but the evidence for compound formation is based on chromatographic and ionophoretic analysis. The mobility values quoted, R_T and M_T, are the chromatographic (propionic acid/n-butanol/water—3 : 6 : 4 v/v) and ionophoretic (0·2 M acetate buffer, pH 5·0) mobility values respectively, relative to tartaric acid. The spray reagents used were aniline hydrogen phthalate[5] (reducing sugars), alkaline silver nitrate[6], and chlorophenol red[7] (acidic groups). In addition, in some cases the solute mixture, after being spotted on to the paper, was treated with a spot of 5 per cent periodic acid pentahydrate solution before irrigation and subsequent spraying[8]. This method causes tartaric acid to yield glyoxylic acid and dihydroxytartaric acid to yield oxalic acid, etc. In the amino-acid systems, the chromatograms were sprayed with ninhydrin[9] and alkaline silver nitrate[6], and the mobilities expressed as R_{glycine} relative to glycine using the propionic acid/n-butanol/water solvent.

The results are shown briefly in Table 1, and indicate the potentials of mixed solute irradiations in vacuum for forming radical addition products, and the readiness with which polymers can be formed. It is hoped that further work will elucidate more thoroughly the structure of the polymers and the addition compounds formed.

We wish to thank the U.K. Atomic Energy Authority, Research Group, Harwell, for supporting the investigation and for maintenance grants.

SOME SOUTH AFRICAN STONE AGE CULTURES

By Dr. R. J. MASON

Archæological Survey of the Union of South Africa

Statistical Analysis of the South African Later Chelles-Acheul and Earlier Fauresmith Cultures

In South Africa our knowledge of the Earlier Stone Age is based on pioneer work that yielded the framework of stratigraphy and broad typo-technological outline of the main prehistoric cultures. Pioneer research regarded the Fauresmith Culture as well separated typologically, technologically and stratigraphically from its ancestor, the Chelles-Acheul. In the Vaal River Basin the South African Chelles-Acheul Stages III–V industries, here described as Later Chelles-Acheul, are found in the later aggradations of the Younger Gravels and overlying calcified sands with a predominantly Middle Pleistocene fauna[1], while the Earlier Fauresmith lies on the surface of the calcified sands and in the Youngest Gravels of the Vaal tributaries[2].

Recent excavations at two Transvaal sites, the Cave of Hearths near Potgietersrus and Wonderboom near Pretoria, have yielded important Earlier Stone Age industries originally classified as Later Chelles Acheul on a non-statistical basis[3,4]. Subsequent study of the Cave of Hearths Earlier Stone Age fauna showed it to be of Later Pleistocene age (Cooke, H. B. S., personal communication), that is, considerably more recent than the Vaal Chelles-Acheul fauna. Industries similar to the Cave of Hearths Earlier Stone Age were found in Later Pleistocene gravels at open sites near the cave. This dating evidence, apparently conflicting with the typology of the industries, led to a detailed statistical study of both the Cave of Hearths and Wonderboom industries, which were statistically compared with Later Chelles-Acheul industries from Vaal Middle Pleistocene gravels at Riverview Estates and Canteen Koppie. It was then found that, despite very close overall resemblances in typology and technology, the Vaal Later Chelles-Acheul and Wonderboom–Cave of Hearths series could be statistically separated, in terms of hand-axe length–width proportions and proportions of dorsally prepared quadrilateral flakes. A Later Pleistocene gravel series from Rooiberg, geographically situated between Wonderboom and Cave of Hearths, was found to have the same statistical characters as those from the latter two sites. Clearly these three industries, all originally classified in non-statistical terms as Later Chelles-Acheul, must be re-classified as Earlier Fauresmith, a culture probably less than half the age of the Later Chelles-Acheul.

Hand-axe length–width proportions. The use of this index in the South African context was suggested by McBurney's distinction between European Acheul and Mousterian hand-axes[5].

In the latter valuable study, McBurney was able to show that Acheul hand-axes were considerably narrower than Mousterian specimens, the Acheul length–width percentage varying from 57·38 to 61·53, while the Mousterian percentage ranges from 69·40 to 77·27.

The South African percentages are as given in Table 1.

Table 1. HAND-AXE LENGTH–WIDTH PERCENTAGES

Culture	No. of observations	Average length–width (per cent)
VAAL LATER CHELLES–ACHEUL		
Riverview Estates Younger Gravels	56	54
TRANSVAAL EARLIER FAURESMITH		
Cave of Hearths Bed 3	62	65
Wonderboom	52	65
Rooiberg Youngest Gravels Earlier Group	45	58
Rooiberg Youngest Gravels Later Group	30	63

These figures indicate that the Vaal Later Chelles–Acheul hand-axes, typologically very similar to Transvaal Earlier Fauresmith, are nevertheless narrower, at the sites listed, just as European Acheul hand-axes appear to be narrower than Mousterian hand-axes.

Quadrilateral flakes with prepared dorsal surfaces. The term 'quadrilateral flake' has been defined[6], and refers to flakes having a quadrilateral plan view. Quadrilateral flakes, like all flakes, may owe their shape either to deliberate or haphazard preparation of the dorsal surface. In Western Europe flakes with deliberately prepared dorsals are called 'Levallois' flakes, a term discontinued in Southern Africa following a decision by the Pan-African Congress of Prehistory in 1947[7]. The latter decision apparently confused the Levallois technique of dorsal preparation with the faceted platform technique, which is not necessarily an aspect of the Levallois technique.

Table 2. DORSALLY PREPARED QUADRILATERAL FLAKE PERCENTAGES

Culture	Total	Percentage dorsally prepared
VAAL LATER CHELLES–ACHEUL		
Canteen Koppie Younger Gravels	46	19
TRANSVAAL EARLIER FAURESMITH		
Cave of Hearths Bed 3	225	48
Wonderboom	63	61
Rooiberg Youngest Gravels Earlier Group	39	56

The figures (Table 2) indicate a more extensive use of dorsal preparation technique in the Transvaal Earlier Fauresmith than the Vaal Later Chelles–Acheul, at the sites listed. The Rooiberg Youngest Gravels Later Group quadrilateral flake sample is too small for inclusion in Table 2.

Some differences in length dimensions of the hand-axe and quadrilateral flake classes in the Vaal Later Chelles–Acheul and Transvaal Earlier Fauresmith samples available may be seen, but these will be set out elsewhere with the full account of the investigation summarized in the present article.

Two main considerations emerge from this preliminary study. It is suggested that the Fauresmith Culture of the type area, Western Orange Free State and Northern Cape, has been defined on the basis of a late stage more clearly distinct from the Chelles–Acheul than its earlier stage as seen in the Transvaal. A broader definition of the Fauresmith Culture, on a statistical basis, is indicated. Secondly, the weakness of a non-statistical classification which failed to distinguish industries similar in typology and technology, but immensely different in age, has been shown, emphasizing the importance of statistical analysis in prehistory.

Parallels between the French Mousterian and Transvaal Earlier Fauresmith Cultures

GOODWIN, in his original description of the Fauresmith Industry, noted the presence of a flake element showing close resemblances to the French Mousterian, which he attributed to the arrival of Mousterian influences in South Africa[8]. Burkitt[9] also directed attention to such similarities, and later workers have repeated these views. Both Goodwin and Burkitt based their opinions on material from the Fauresmith type area, namely, the Northern Cape and Western Orange Free State. Later, the Fauresmith Culture was recognized beyond the confines of the type area, while recent excavations in the Cave of Hearths in the Makapan Valley and Wonderboom near Pretoria have given adequate material for detailed examination of the culture in the Transvaal. No detailed comparison of the Fauresmith and French Mousterian was made until 1956, when I was able to carry out a brief comparative study generously financed by the Wenner Gren Foundation for Anthropological Research.

Intercontinental dating comparisons of Stone Age cultures are insecure, but it is significant that the French Mousterian culture falls within the European Upper Pleistocene[10], while the Earlier Transvaal Fauresmith belongs to the local Later Pleistocene, as seen in the Makapansgat Cave of Hearths fauna (Cooke, Dr. H. B. S., personal communication), suggesting a broadly equivalent position in the world time-scale. F. Bordes[11] observes at least six variants within the French Mousterian group, of which only two concern us here, the 'typical' Mousterian and Mousterian of Acheulean tradition. The typical Mousterian appears to be a variant of the Mousterian of Acheulean tradition, its typology consisting of similar flake classes without the higher proportion of hand-axes and cleavers found in the latter industry. Both industries are frequently found in different beds at the same site, such as Le Moustier and Abri Brouillard in the Dordogne.

With the kind permission of Mr. Harper Kelley, I was able to study the Abri Brouillard industries in the Musée de l'Homme, Paris. Peyroney and Bourrinet excavated Abri Brouillard in 1907, finding two superposed Mousterian beds overlain by a thin 'Aurignacian' horizon[12]. The large number of irregular artefacts and waste fragments in the series suggests that it is reasonably representative, unlike most early collections. The Bed 1 industry may be classified as typical Mousterian and that from Bed 2 as Mousterian of Acheulean tradition, with a high proportion of denticulate flakes in both industries. A number of close typological and technological similarities were seen in comparing the Mousterian of Acheulean tradition Bed 2 industry from Abri Brouillard and the Transvaal Earlier Fauresmith industry from Cave of Hearths Bed 3, on a statistical basis. The detailed comparisons will be published elsewhere ("Cave of Hearths", monograph in preparation). Here we are concerned only with main features. The 'typical' Mousterian industry of Abri Brouillard Bed 1 is similar to the Bed 2 series but has a lower proportion of bifaced hand-axes and cleavers, as shown in Table 3.

Table 3. FRENCH MOUSTERIAN

Site	Hand-axes and cleavers (per cent)	Flakes (per cent)	Total
Brouillard Bed 1	1	99	527
Brouillard Bed 2	27	73	481

The reason for the variable class proportions is unknown, but might be response to differing seasonal needs.

A similar position is seen in the Transvaal Wonderboom and Cave of Hearths Bed 3 series, now classified as Transvaal Earlier Fauresmith (see preceding communication). The Wonderboom series consists of the same hand-axe, cleaver and flake classes found in Cave of Hearths Bed 3; but the flake classes are predominant, as in the 'typical' Mousterian of France (Table 4).

Table 4. TRANSVAAL FAURESMITH

Site	Hand-axes and cleavers (per cent)	Flakes (per cent)	Total
Wonderboom 76–79 in.	4	96	242
Wonderboom 39–42 in.	2	98	285
Wonderboom 6–18 in.	0·3	99·7	366
Cave of Hearths Bed 3	20	80	1,083

At Wonderboom we have the first evidence in Africa for the existence of a Fauresmith parallel to the French Typical Mousterian industry. Comparison of the Abri Brouillard, Cave of Hearths and Wonderboom industries shows not only general typo-technological resemblances but also similar variable production of the flake component in the Transvaal Fauresmith, French Typical Mousterian and Mousterian of Acheulean tradition cultures. While earlier comparisons were with the Mousterian in general, Wonderboom enables us to compare the Transvaal Fauresmith more specifically with the French *Mousterien typique*.

The Cave of Hearths Earlier Stone Age industries, best represented in Bed 3 at that site, were originally classified as Later Chelles–Acheul. The later Pleistocene fauna afterwards found with these Earlier Stone Age industries, among other factors, showed that they could not possibly be the same age as the Later Chelles–Acheul which, both on the Vaal River and in East Africa, is associated with a fauna of more archaic aspect. Subsequent statistical study showed that despite the close general resemblances of the Cave of Hearths Earlier Stone Age series and the Vaal Chelles–Acheul, they could be separated from the latter industries in statistical terms (see preceding communication). Statistical study of the Wonderboom series showed its close resemblances to the Cave of Hearts Bed 3 industry, in all except class proportions, forcing me to change my 1957 non-statistical classification of Wonderboom[13] as a Later Chelles–Acheul site and assign the entire series to the Transvaal Fauresmith culture. For these reasons I have come to suspect non-statistical classifications of Acheul industries found elsewhere, such as the 'Upper Acheul' industries from Mount Carmel[14] and Jabrud[15] in the Eastern Mediterranean area. Like the Wonderboom and Cave of Hearths Earlier Stone Age industries, these 'Acheul' series might prove to be considerably later than their non-statistical classification indicates. They may prove to be Eastern Mediterranean parallels of the French Mousterian of Acheulean tradition. At Jabrud Site 1, the 'Acheul' beds are intercalated with flake industries said by d'A. Waechter[16] to be "Acheulean without hand-axes", in my view, possibly the same as Typical Mousterian, though Bordes, who has studied the Jabrud series in detail, describes the Jabrudien as an eastern facies of the la Quina Mousterian[17].

So we are confronted with a curious dualism in Acheul derivative cultures spread from France, possibly to the eastern Mediterranean and appearing unexpectedly on the southern end of Africa at Wonderboom and Cave of Hearths. The racial type found with the French Mousterian is Neanderthal, while the Fauresmith horizon in Cave of Hearths Bed 3 yielded a jaw fragment tentatively classified as Neanderthal[18].

There can be little doubt that for the most part evolution in the South African Stone Age continues undisturbed from the very beginnings of the Stone Age until its end, with occasional migrations from neighbouring parts of Africa accounting for intrusive cultures such as the Smithfield and Sangoan, both the latter derived from the Congo. The unbroken nature of the culture sequence disproves claims for a 'Mousterian' invasion from the north, but does little to account for the Fauresmith–Mousterian parallels indicated in the present article. For the present, these widely separated racial and cultural resemblances, occurring in radically different ecological settings, must be regarded as an enigma, unless they are explained by derivation from a single source followed by evolution in isolation during an immensely long period of time. The preservation of genetic and cultural similarities could have been due to an unexplained biological and psychological conservatism.

Acknowledgments are due to the Wenner-Gren Foundation for Anthropological Research, the generous financial support of which made possible part of the research summarized in this article. Discussion with Mr. B. D. Malan, director of the Archæological Survey, led to modification of the views given here.

LETTERS TO THE EDITORS

OCEANOGRAPHY

Measurements of the Pacific Equatorial Countercurrent

As part of *Doldrums*, the third of three International Geophysical Year oceanographical expeditions of the Scripps Institution of Oceanography, direct current measurements were made in the centre of the equatorial countercurrent, 7° 52′ N., 107° 30′ W. The techniques were similar to those used three months previously, when measurements were made of the Cromwell current at the equator, 140° W.[1]. In the top 300 m. observations were made by suspending a propeller-type current meter (a modified Roberts meter) from a drifting ship and measuring the apparent velocity at different depths from the flow of water past the meter while at the same time observing by radar the drift of the ship from a fixed reference point—a taut wire buoy anchored in 2,200 fathoms. Below 300 m. measurements were made by following the drift of Swallow current floats[2].

Calculations of the geostrophic current as well as other considerations have led to a picture of the countercurrent as a shallow current the maximum velocity of which is to be found somewhat below the surface, but the flow of which is confined almost entirely to the region in and above the sharp tropical thermocline. Direct current measurements made on *Doldrums* modify this picture. The highest velocities in the countercurrent are found above the thermocline, and the peak velocity is found beneath the surface but in the mixed layer. However, the countercurrent does not vanish beneath the thermocline but continues to flow east at speeds of 15–20 cm./sec. Fig. 1 is a plot of the east–west current component as measured on *Doldrums*. The current profile above 200 m. is a composite of 12 Roberts meter stations taken over a two-week period; below 200 m. the curve is drawn to the six Swallow current float measurements summarized in Table 1. The depth of the thermocline as measured by the bathythermograph is also shown.

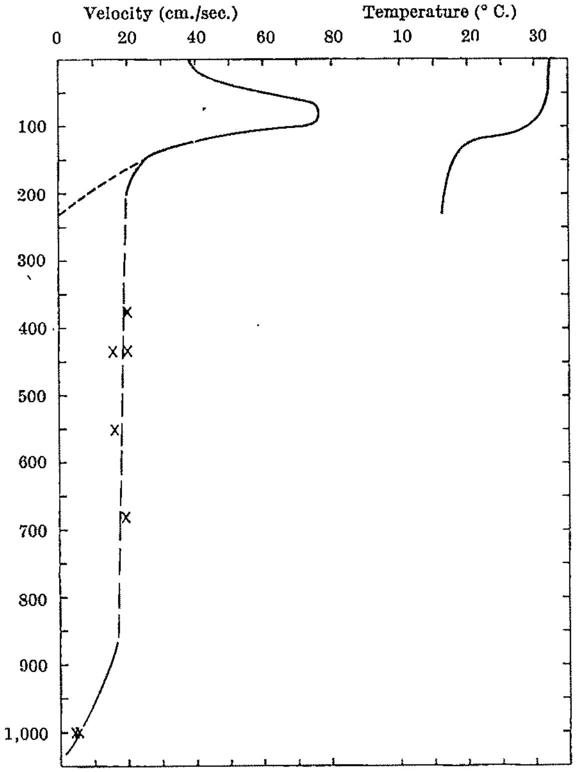

Fig. 1. Current and temperature profile in Pacific equatorial countercurrent, 7° 52′ N., 107° 30′ W. Transport calculation above and below the thermocline were made relative to the dashed line

Table 1

Date	Hours tracked	Depth (m.)	Velocity (cm./sec.) — direction (toward)
August 12	7·2	370	20 — 080°
15	12·5	680	20 — 100°
16	16·0	590	16 — 085°
17	14·2	1,000	5 — 085°
18	7·3	1,000	5 — 135°
26	14·9	430	16 — 115°

The results summarized in Fig. 1 indicate that the countercurrent transports more water below the thermocline than above it. The width of the countercurrent during this period was 250–300 km. Making some allowance for a decrease in the current near its edges a rough estimate of the transport of the countercurrent based on this one profile is 20×10^6 m.^{3}/sec. for the region above the thermocline and 30×10^6 m.^{3}/sec. for that below the thermocline. The estimated transport above the thermocline agrees with that given by Sverdrup[3] for the countercurrent ($20–25 \times 10^6$ m.^{3}/sec.).

The problem of water balance and mass transport in the equatorial Pacific must be re-examined and at least one detailed north–south section of direct current measurement stations is required. The measurements of the Cromwell current in May, 1958, showed[1] an eastward transport of 30×10^6 m.^{3}/sec. The present observations imply that there is an additional transport of 30×10^6 m.^{3}/sec. in the countercurrent below the thermocline. These additions more than triple the total eastward transport in the equatorial Pacific as given by Sverdrup[3].

GEOPHYSICS

Geomagnetic Micropulsations

A DETAILED analysis of geomagnetic micropulsations has been carried out on records obtained at Albert Head between November 29, 1956, and February 16, 1957. Albert Head (approximately 48° 23′ N., 123° 29′ W.) is situated by the sea near Victoria, Vancouver Island, British Columbia. The records were obtained from three mutually perpendicular air-core induction coils, each 20 ft. in diameter, mounted in a rigid wooden octahedron[1]. The records were analysed by visual inspection: more than 300 fluctuations were identified with periods ranging from 15 to 400 sec. Their amplitudes were read and reduced by simple computation to components X (north), Y (east) and Z (vertically downwards). Plots were made of these three components against the period T of the oscillations, but yielded little information. There was a tremendous scatter in the points, and it was impossible to draw any mean curve through the data. The only conclusion that could be drawn was that, in general, the amplitude appeared to increase with the period.

The same data were then taken and the amplitude of every fluctuation divided by the K_p index at the time the observation was made. Plots were drawn of X/K_p, Y/K_p and Z/K_p against T. There was a very considerable reduction in the scatter, which was further reduced if local K indices (instead of K_p) were used. A least-squares analysis gave extremely interesting results. The graphs of both X/K_p (Fig. 1) and Y/K_p (Fig. 2) consist of parts of two straight lines—the change of slope occurring at a period of about 2 min. An investigation is now being made to see whether these may represent two different kinds of magnetohydrodynamic waves—poloidal and torsional oscillations. The graph of Z/K_p (Fig. 3) is almost linear. It would be interesting if similar calculations were made at other stations and at different periods of the year. The above method of analysing the data may not be the best, but was continued since the early results were encouraging. The smallest K_p value was 1·0. A detailed account of this study is being prepared.

Storm-Time Increase of Cosmic-Ray Intensity

DURING the period of the International Geophysical Year (July 1957–February 1958) there were several occasions in which the intensity of cosmic rays increased by a few per cent. Two typical events, which occurred on September 13, 1957, and February 11, 1958, respectively, will be described here.

Since the change in intensity is complicated by the diurnal variation, the world-wide type of decrease and so on, the increases observed at any particular position may be depressed or exaggerated. In order to study the characteristics of an increase more clearly, Fig. 1 was prepared. The four curves represent the variation in intensity averaged for two or three stations distributed symmetrically in geographical longitude (Table 1), so that any diurnal variations may be approximately smoothed out[1]. From Fig. 1 it is seen that the cosmic-ray intensities increased

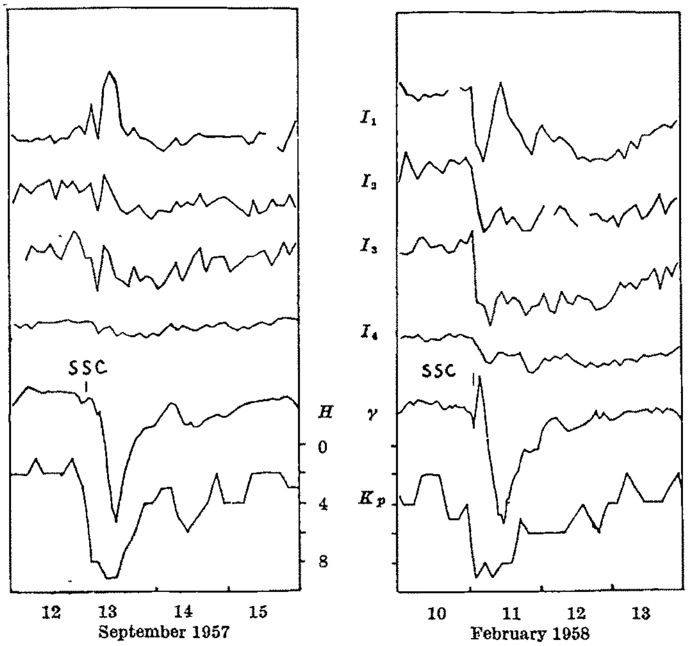

Fig. 1. World-wide variations of cosmic-ray intensities obtained by averaging data from the station in Table 1, and the change of magnetic activity

abruptly by about 2 or 3 per cent on a world-wide scale regardless of diurnal variation. (This does not exclude the possibility of the longitude variation of increment.) The times of maximum intensities were 9 hr. ± 1 hr. on September 13 and 11 hr. ± 1 hr. on February 11, respectively.

The variations of horizontal magnetic force observed at Kakioka as well as the international magnetic activity index (K_p), are also plotted in Fig. 1. It was found that the increase in intensity of the cosmic rays coincided with the severest phase of magnetic storms. The magnetic storm in February was one of the severest in recent years, and that in September was almost as severe. Many magnetic observatories reported a K_p index of 9 for the interval containing the cosmic-ray increase in each storm. It is of interest that, during these storms, auroræ were seen in such low latitudes as those of Japan[2].

Large solar flares, which appear to be the cause of these storms, occurred at 02h. 45m. on September 11, and at 21h. 08m. on February 9, respectively; none was seen before or during the actual time of the increases. These increases, therefore, seemed to differ from the so-called extraordinary increases of cosmic rays, a fact that is confirmed by the mode of variation in latitude shown in Fig. 2. Usually, the solar cosmic rays predominate in higher latitudes, but the increases described here were most pronounced in lower latitudes.

The variation with latitude of the increment in Fig. 2 may be outlined as follows: the increment increases slightly with the latitude from the equator to about 50° N.; it then decreases steeply, and reaches a constant level which is rather difficult to evaluate, however, because of the process of normalization.

In order to illustrate the dependence upon energy of the increments, a comparison in variational amounts of the increase and decrease was made as shown in Fig. 3. The increment seems to be proportional to the amount of decrease, which is itself a function of altitude and component. Since the stations chosen lie in the region of latitude lower than 50° N., it may be said that the dependence upon energy of the cosmic-ray increase is nearly the same as that of the decrease.

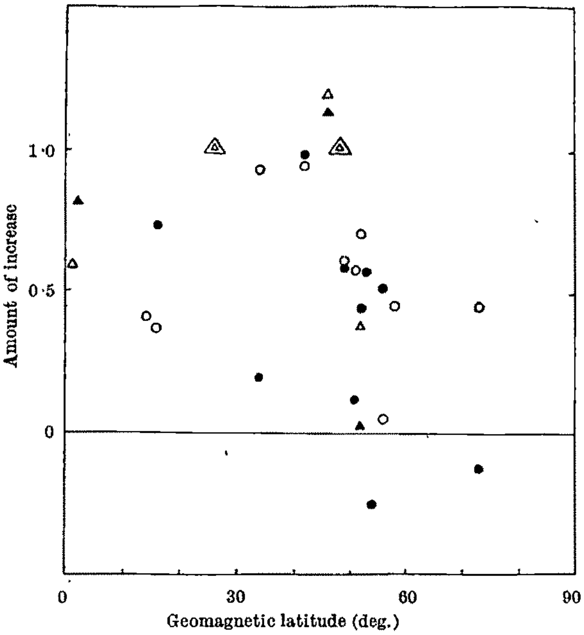

Fig. 2. Variation with latitude of the cosmic-ray increment. Each increment is calculated as the difference in intensity between the time of the increase (6 hr. around each maximum) and 6 hr. before and after the increase. An adjustment has been made to eliminate dependence on longitude. Because the increases were less significant, results for American regions are omitted. Circles, sea-level stations; triangles, mountain stations; ○ and △, September; ● and ▲, February. Double triangles, stations for I_1 in Fig. 1 which were used as normalization points

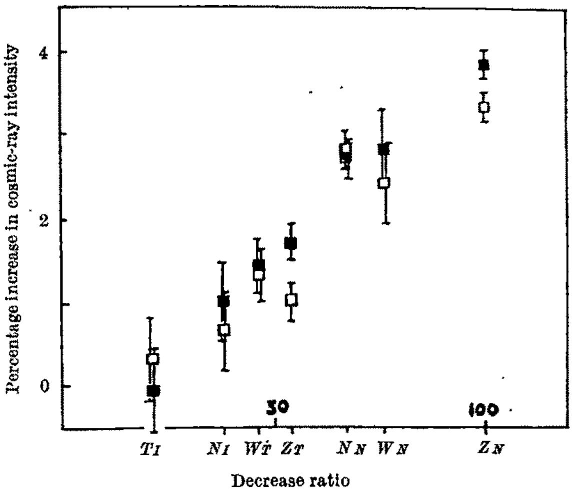

Fig. 3. Quantitative relation between the world-wide decrease and increase of cosmic-ray intensity. The scale for the abscissa was obtained by averaging the amounts of decreases occurring during 1957 at corresponding stations using the apparatus indicated, with an estimated error of approximately 3 on the scale. Abbreviations: Z, Zugspitze; W, Weissenau; N, Norikura; and T, Tokyo. Subscripts: N, neutron; T, meson monitor; and I, ion chamber. The errors in ordinate are the statistical values. The zero line of the ordinate is subject to slight adjustment in the calculation of intensity-level

We wish to thank the staffs of the cosmic-ray observatories throughout the world for the results used and Dr. Y. Miyazaki for allowing us to use the data compiled in the World Data Centre of Cosmic Rays in Japan.

Occurrence of Giant Travelling Ionospheric Disturbances at Night

A RECENT publication[1] from this laboratory has discussed the existence of large travelling ionospheric disturbances which during winter daylight hours travel from south to north over the east coast of Australia. This type of disturbance first described by Munro and Heisler[2] has been tracked from Hobart to Townsville, a distance of 3,000 km. with no apparent change in amplitude. Moreover, the frontal extent of the phenomenon is at least 1,000 km. and may be greater. Munro[3] found evidence in the northern hemisphere ionosonde records of similar disturbances travelling south during the winter months. This has been confirmed by Wells[4] and verified at Stanford University in a recent report[5] which shows how backscatter techniques have been used to find many examples of giant travelling ionospheric disturbances, some of which have been shown to extend at least from the east to the west coasts of America and to travel distances of 4,000 km.

It was previously thought that this phenomenon was confined to daylight hours, but recently careful investigation of night ionosonde records has revealed anomalies which are obviously a counterpart to the disturbances discussed above.

This phenomenon is characterized by a rapid fall in virtual height of the F-layer accompanied by a reduction in critical frequency; a cusp then appears at the top of the F-layer in the form typical of a daylight record with $F1$ stratification. This stratification then disappears and as a consequence leaves a high F region trace. The layer then slowly falls to its original height. Part of the sequence at a particular ionospheric station is shown in Fig. 1.

These disturbances are infrequent and seldom occur more than once a night or on more than two or three nights a week, and consequently identification on ionosonde records from a number of stations is conclusive. Fig. 1 is a series of tracings showing a disturbance on records from Brisbane (27° 28′ S., 153° 2′ E.), Camden (34° 03′ S., 150° 40′ E.) and Townsville (19° 10′ S., 146° 58′ E.). The difference in time of occurrence at the various stations is obvious and is consistent with a disturbance travelling approximately due east with a speed of 8 km./min. Moreover, since these stations lie in an approximate north–south line the fronts must extend at least from Camden to Townsville, a distance of 1,800 km. A similar disturbance occurring on the Camden record at 2220 hr. on June 26, 1957, has been positively identified at Brisbane and Townsville and was travelling 46° east of north with a speed of 16 km./min. Watheroo (30° 18′ S., 115° 56·6′ E.) record for the same night showed a similar disturbance but with a difference in time which would suggest that the disturbance front was curved with a direction of travel north-west in Western Australia and north-east in Eastern States. Unfortunately, there are no ionospheric stations in the east – west line between Camden and Watheroo, a distance of 3,300 km., to determine this positively.

There are as yet insufficient results to interpret the seasonal variation of occurrence, although examples have been found during March, June and July. Research into the phenomenon is continuing and it is hoped that the discovery of such disturbances in the much simpler ionospheric conditions existing at night may help materially in determining the mechanics of the phenomenon.

Grateful acknowledgment is made to the Ionospheric Prediction Service of the Department of Interior and the Geology and Geophysics Division of the Bureau of Mineral Resources for their co-operation in providing ionosonde records for this research. This work is part of the investigations of the Sydney Laboratory of the Radio Research Board in the

Origin of Upper-Atmosphere Lithium Atoms responsible for the New Twilight Airglow at 6708 A.

A NEW emission line near 6708 A. has been reported recently by Delannoy and Weill[1] to be present on twilight spectrograms obtained in Adélie Land, Antarctica, during October 1957. Gadsden and Salmon[2] also report the appearance of the same line in twilight spectra photographed at Hallett Station, Antarctica, during August, 1958, and at Invercargill, New Zealand, on September 5, 1958. In both instances, the authors attribute the new line to resonance radiation from the 2^2S—2^2P transition in the neutral lithium atom at 6707·8 A.

In a further communication, Barbier, Delannoy and Weill[3] estimate the ratio of the number of neutral atoms of lithium to those of sodium at the level of twilight emission, taking into account the very different energy of the exciting solar radiation at 5893 A., and 6708 A. respectively. From an observed intensity ratio, $I_{6708}/I_{5890+5896}$, equal to 0·1 : 1, they compute an abundance ratio of $N_{\mathrm{Li}}/N_{\mathrm{Na}}$ of $\sim 0{\cdot}006$, about three times greater than that found in stony meteorites[4]. Since the lithium/sodium concentration ratio for oceanic waters[5] is only $\sim 2 \times 10^{-5}$, they conclude that both the sodium and lithium atoms in the high atmosphere are meteoritic, and not terrestrial in origin.

Gadsden and Salmon[2] infer from their intensity ratio measurements an even greater relative concentration of lithium, with a lithium/sodium ratio of $\sim 0{\cdot}05$, or some twenty-five times the expected value if both atoms are derived from meteoritic dust. They report also that altitude measurements of both the normal sodium and lithium twilight radiations revealed that, between August 13 and September 5, the height of the lithium emission (relative to that of sodium) decreased by $\sim 0{\cdot}4$ km. per day, the equivalent of a steady rate of fall of 0·46 cm. per sec. for the 'lithium cloud'.

On inserting this latter value in the classical Stokes's equation, together with the following adopted values for the remaining parameters, namely, air density at 80 km., $2{\cdot}5 \times 10^{-8}$ gm. per cm.^{3}; air viscosity at 190° K., $1{\cdot}2 \times 10^{-4}$ gm. per cm. per sec.; density of meteoritic dust, 3·5 gm. per cm.^{3}, a mean particle diameter of 5·4μ is obtained. According to Öpik[6], this is of the right order of magnitude if the particles in the cloud with which the lithium atoms are associated are derived from micro-meteors.

However, when such an origin is invoked, a major difficulty immediately arises in any attempt to explain the observed differential rate of fall of the lithium emission, since this would not be expected if both lithium and sodium atoms were associated with a falling cloud of meteoritic material.

The above argument, when taken in conjunction with the excess values of the lithium/sodium abundance ratio observed in 1957 and 1958, makes any hypothesis of a meteoritic origin for either element suspect. On the other hand, it lends credence to the recently published statement by the American Committee for the International Geophysical Year[7] that the presence of lithium in the upper atmosphere could be related, as was the recent artificial aurora[8], to nuclear (lithium bomb) explosions detonated at high altitude over the central Pacific Ocean during the period of the International Geophysical Year programme.

If the latter explanation is correct it is of interest to compute a revised value for the mean particle diameter in the descending cloud on the assumption that the radiating lithium atoms are trapped within a cloud of lithium oxide smoke of density 2·1 gm. per cm.^{3}. Taking values for the remaining Stokes's parameters as before, the average particle size is now $\sim 7{\cdot}0\mu$; and if the ejection of the lithium atoms occurred initially at a height of ~ 160 km. the twilight phenomena might be expected to be present for about 90 days after the nuclear explosion. During this interval the 'lithium cloud' would have fallen from the upper to the lower limit of resonance emission.

From the evidence of the August, 1958, observations it appears that there was a five-day lag between the time of the nuclear detonation on August 1 and the first appearance of twilight lithium radiation. Thus the initial rate of fall must have been considerably higher than the steady descent of 0·4 km. per day observed afterwards, a probable value being ~ 10 km. per day if the upper limit of twilight emission is taken to be 110 km.

Taking all the above facts into consideration, it appears highly probable that the lithium airglow emission observed in October 1957, and again in August–September 1958, was man-made, and thus wholly unrelated to the passage of meteoritic dust through the Earth's upper atmosphere.

If indeed this is correct, the hypothesis of a meteoritic origin for both lithium and sodium atoms suggested by Barbier, Delannoy and Weill[3] is invalidated, leaving the important question of the terrestrial, or extra-terrestrial, origin of upper-atmosphere sodium still unanswered.

Magnetostriction and Palæomagnetism of Igneous Rocks

THE magnetization of dated igneous rocks has been much used for the study of the directions of the geomagnetic field in remote geological periods. This method is based on the supposition that igneous rocks become magnetized parallel to the field in which they cool. Its validity has been questioned on the grounds that the stress-histories of rocks may have a substantial influence on the directions of their remanent magnetic moments[1–3]. In particular it has been suggested that igneous rocks which cool under stress become magnetized in the direction of the prevailing field, but that when the stresses are released, substantial changes in direction may occur. Sills cooling under load and lava flows subject to cooling stresses present situations of the type envisaged: when specimens of such rocks reach the laboratory their original stresses have been relieved by erosion of overlying rock and the removal of the specimens from the ground.

Presumptive evidence for such magnetostrictive effects has been given by Graham, Buddington and Balsley[3], who subjected a number of metamorphic rocks to linear compressions of 250 kgm./cm.^{2} without heating and found reversible deflexions of up to 30° in the directions of magnetization. (It may be noted that no authors have used metamorphic rocks to draw conclusions about the directions of the Earth's magnetic field.) Stacey has pointed out[4] that, while the pronounced effect of isothermally applied axial compression is theoretically reasonable, it does not follow that thermo-remanent magnetization acquired under stress will show irreversible deflexions when the stress is removed. Field evidence[5] suggests the absence of large magnetostrictive effects.

A crucial laboratory experiment consists of subjecting igneous rock specimens to axial stress while they cool from high temperatures in a magnetic field, and then comparing the directions of the resulting magnetic moments after subsequent release of stress with that of the field. Accordingly, we have built a special non-magnetic press and heating system and made experiments on a number of igneous rocks from eastern Australia for which palæomagnetic data have been reported. Twenty cylindrical specimens covering a wide range of rock types, ages and geological environments, namely, Quaternary basalts, Mesozoic dolerite sills, Permian basalts, Devonian basalt and rhyolite flows, and Silurian porphyry of andesitic composition were placed in the press with their axes in the magnetic meridian. They were heated to 650° C. in a nitrogen atmosphere, held at that temperature for 15 min. and then allowed to cool over a period of several hours under an axial load of 500 kgm./cm.^{2}. The directions of magnetization of all the specimens were measured after their removal from the press. Errors of measurement and of alignment of specimens in the press were estimated by means of a duplicate set of specimens, which were given the same heat treatment, but without stress. The experiments were carried out in a non-magnetic hut where the geomagnetic dip I is 66° ± 1°. The results are summarized in Table 1, where $\bar{\theta}$ is the mean of the angles between the magnetic moments of the specimens and their axes, and δ is the standard deviation of the individual variations from the mean. Within the limits of the experiment, all the rocks, both stressed and unstressed, acquired moments in the direction of the field in which they cooled.

Table 1

	No. of specimens	I	$\bar{\theta}$	δ
Cooled under no load	20	66°	65·2°	2·5°
Cooled under 500 kgm./cm.^{2}	20	66°	65·4°	2·6°

This excellent agreement between the dip and the directions of artificial thermoremanent magnetization of the stressed and unstressed rocks indicates that large systematic errors due to magnetostriction are most improbable in igneous rocks of types normally used for palæomagnetic work.

PHYSICS

'Whistler Mode' Echoes remote from the Conjugate Point

Echoes of very low frequency radio signals from station *NDT* on 17·44 kc./s. in Tokyo (25° N. geomagnetic latitude) with delays of about 0·2 sec. have been detected at Hobart, Tasmania (51° S. geomagnetic latitude). The Eckersley–Storey theory of 'whistler' propagation predicts that 'whistler mode' signals from Tokyo would return to the Earth's surface at a point (the geomagnetic conjugate point to Tokyo) near Darwin, Northern Territory, some 3,500 km. from Hobart.

The signals used were ⅛-sec. pulses sent every second for a 4-min. period. These transmissions were specially arranged by the Australian National Committee of the International Geophysical Year for a conjugate point experiment. The receiving equipment consisted of a single-turn, crossed-loop system, 70 ft. high, fed through a goniometer into a made-up receiver having four tuned radio-frequency stages and two tuned intermediate-frequency stages. The enclosed area of each loop was about 900 m.^{2}, the receiver intermediate frequency was 750 c./s. and the overall band-width was about 15 c./s. The signals were recorded on tape. The null direction of the crossed-loop system was adjusted so as to reduce considerably the direct signal since the *NDT* transmitter radiated a strong residual signal in between the pulses.

The direct signal from *NDT* was received with a strength of about 150 μV./m. during the day. All measurements were made at about 1250 local time. A series of distinct echoes were heard on only one of the five periods observed (1251½ E.A.S.T., September 30). On analysis these were found to have an average time delay of 0·21 sec. and a strength of 3 μV./m. Four direct pulses, each followed by an echo of about this delay, are shown in Fig. 1.

As only a few echoes were heard it was not possible to locate the source by direction-finding methods. It seems most likely from the delay times, however, that the echoes travelled via the 'whistler mode' from Tokyo to somewhere around Darwin and to Hobart via the Earth – ionosphere wave-guide mode. The observed 0·2-sec. delay is in agreement with observed whistler dispersions (from 30 to 50) for this geo-

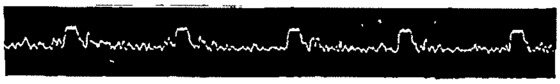

Fig. 1

magnetic latitude[1] and with a similar whistler mode echo experiment[2], using the station *NPM*, which is also on about this same geomagnetic latitude. The actual time spent in the whistler mode is found by adding the travel time for the direct pulse from Tokyo to Darwin (0·02 sec.). This time is then 0·23 sec.

Use can be made of these results to estimate the minimum electron density on the line of force originating from the transmitter. Whistler mode echoes of very low-frequency stations have an advantage over natural lightning flash whistlers in that the position of the transmitter is readily and accurately known. As borne out by this experiment, the assumption that short whistlers originate near one's conjugate point could lead to an error of more than thirty degrees of latitude.

The whistler mode delay time for a signal of frequency f travelling along a line of force in a medium of plasma frequency f_p and gyro frequency f_H is given by Storey's[3] equation (15) provided $f_H \gg f$ and $f_p^2 \gg f f_H$:

$$t = \frac{1}{2c}\int f_p\,(f f_H)^{-1/2}\,\mathrm{d}s$$

If we assume a dipole field and a constant electron density along the line of force (neglecting, for the moment, the effect of the lower ionosphere), we can get the approximate expression:

$$t \approx \frac{R_0}{c} f_{p_0}\,(f f_{H0})^{-1/2} \int_0^{x_g} (1-x^2)^{3/2}\,(1\ 3x^2)^{1/4}\,\mathrm{d}x$$

$$\approx \frac{R_0}{c} f_{p_0}\,(f f_{H0})^{-1/2}\, x_g(1-\tfrac{1}{4}x_g^2) + \text{terms in } x_g^5 \qquad (1)$$

where R is the distance from the Earth's centre (in units of the Earth's radius) and x is the sine of the geomagnetic latitude angle. The subscripts 0 and g refer to values in the geomagnetic equatorial plane and at the Earth's surface respectively. The maximum value of x is $x_g = \sin 25° = 0{\cdot}4$, so to within an accuracy of a few per cent we may neglect terms in x^4.

To this must be added a correction to take account of retardation through the lower ionosphere. Considering only the F region and assuming a parabolic layer of semi-thickness y_m, critical frequency f_{pc} and magnetic dip angle φ and assuming all other quantities to be constant within the integration limits, we find the correction to be applied is:

$$\Delta t = \tfrac{1}{4}\pi f_{pc}\,(f f_H)^{-1/2} y_m \operatorname{cosec}\varphi \qquad (2)$$

We can apply equations (1) and (2) to find f_{p_0} at R_0. On substitution of $x_g = \sin 25°$ and $t + \Delta t = 0{\cdot}23$ sec. we find $\Delta t = 0{\cdot}04$ sec. $R_0 = 1{\cdot}22$ radii and $f_{p_0} = 1{\cdot}75$ Mc./s. This suggests an electron density of about 20,000 cm.$^{-3}$ at a height of about 1,400 km.

We wish to thank Dr. G. R. Ellis, Upper Atmosphere Section, Commonwealth Scientific and Industrial Research Organization, for his useful suggestions.

Multiple Geiger Counter Telescope Measurements of the Directions of Air Shower Particles

A MULTIPLE Geiger counter telescope was described recently by Shen and Singer[1], for which it was claimed that it responded preferentially to air showers the axis of which were parallel to the direction of the telescopes. Such an arrangement was tested by Layson, Malos and Millar[2] in a scintillator array with which total number of particles, situation of core and direction of shower axis were determined. The result of the latter investigation, namely, that the multiple Geiger counter telescope does not select in larger proportion air showers of preferred orientation, is supported by an unpublished experiment made by me in 1948 while at the School of Physics, University of Melbourne.

The arrangement used consisted of two Geiger counter telescopes, separated by 1 m., which could be tilted independently around an east–west axis. Each telescope consisted of two counters, 20 cm. long and of 3 cm. diameter, separated by 14 cm. A third counter could be introduced either in line or just outside the space joining the two outermost counters. The resolving time of 8 μsec. gives a rate of accidental counts of 10^{-3} per hr. for both the fourfold and sixfold coincidences, the main contribution being the accidental coincidences between the two telescopes.

The results of measurements made in a tent at an altitude of 1,750 m. are given in Table 1.

Table 1. SHOWER-RATE IN COUNTS PER HR. AT DIFFERENT ZENITH ANGLES

Zenith angle		Counters in each telescope		
Telescope 1	Telescope 2	2 counters	3 counters in line	3 counters centre out of line
0°	0°	1·96 ± 0·29*	1·56 ± 0·27	1·19 ± 0·24
30° N.	30° N.	1·50 ± 0·27	1·41 ± 0·24	0·98 ± 0·22
60° N.	60° N.	1·23 ± 0·22	0·66 ± 0·17	
90° N.	90° N.	1·25 ± 0·23	0·77 ± 0·16	0·94 ± 0·22
30° N.	30° S.		1·04 ± 0·22	
60° N.	60° S.		0·67 ± 0·17	

* The errors given are standard errors.

While the statistical accuracy is not sufficient to draw detailed conclusions, it is sufficient to show that such an arrangement of Geiger counters as was used does not respond selectively to showers incident within the opening angle of ± 12° of the telescopes. However, taking the three measurements at 60° and 90°, which give a mean of 0·70 ± 0·10, as general background due to showers arriving in all directions, we find that 0·87 ± 0·29, or about half the counts measured in the vertical position, are due to showers arriving from the zenith region. The excess of 0·71 ± 0·26 above background at 30° zenith angle gives an effective acceptance angle of ± 20–30° for that part of the rate which exceeds the background. The broadening can be explained both by the divergence of particle tracks in showers and by the fact that one particle only may frequently pass through two counters. The second effect is shown in the excess of the out-of-line measurements, the first in the excess of 0·37 ± 0·24 above background of the measurement at 30° N. 30° S., that is, with a divergence of the two telescopes of 60°.

As soon as it was evident that multiple telescopes were not sufficiently efficient in selecting showers incident in preferred directions the experiment was discontinued.

Permeability of Porous Media

Over the past decade much significance has been given to distribution of pore size characteristics in computing both saturated and unsaturated permeability of porous materials. Oil industry investigators[1] and soil scientists have adopted this approach to permeability computation with considerable success.

Childs and Collis-George[2] proposed a theory wherein flow is determined by the pore radii and by the probability of continuity of pores of different radii in adjacent planes. Marshall[3] greatly facilitated computation by using arbitrary equal volume components of the porosity.

Both these approaches show defects. The ratio of the observed and calculated permeability at saturation was used by Childs and Collis-George as a 'matching factor' to compute values for unsaturated permeability. If instead of the 'matching factor' (M), pore radii (not $1/h$) and the Poiseuille coefficient 1/8 are used, the computation yields the same result as the method of Marshall. Using the 1–½ mm. sand data of Childs and Collis-George, both the above methods give a calculated permeability at saturation of 76×10^{-8} cm.² against the experimentally determined value of 144×10^{-8} cm.². The form of the curve calculated by these methods for permeability against water-filled pore space does not fit the experimental findings. In the following paragraphs an alternative theory is proposed.

In a porous medium of porosity ε, the effective area available for flow may be defined with reference to the volume distribution of pore space thus:

$$\frac{\text{effective pore area}}{\text{pore volume}} = (n^2\pi r^2/n^3\pi r^3) \,.\, (k_1/k_2)$$

where there are n^3 pores or radius r in unit volume of the medium; k_1 and k_2 are characteristics of the shape of pore and for nearly spherical pores may be neglected in the subsequent derivation. From this relationship it can be shown that the effective pore area available for flow per unit area of section is $\varepsilon^{2/3}$. If there are m pore classes each occupying a volume component ε/m of the total porosity, then the effective flow area presented by each pore class is $\varepsilon^{2/3}/m$. However, flow is determined by the pore interaction or continuity between adjacent sections, so that permeability is determined by the sum of:

$$\begin{array}{l} a_1a_1r_1^2 + a_1a_2r_2^2 \ldots\ldots a_1a_mr_m^2 \\ \vdots \\ a_ma_1r_m^2 + a_ma_2r_m^2 \ldots\ldots a_ma_mr_m^2 \end{array}$$

where a_1, a_2, etc., are the pore areas devoted to pores of radius r_1, r_2, etc., in unit area of section.

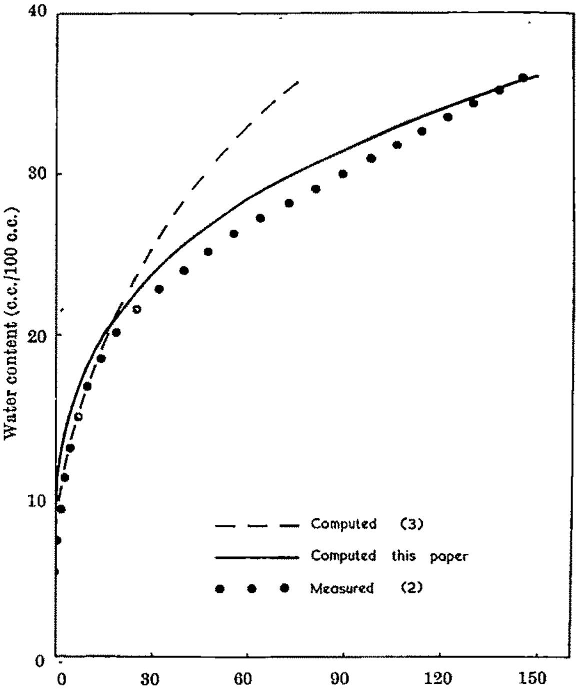

Fig. 1

Since there are m equal volume components of the porosity:

$$a_1a_1 = a_1a_2 = \ldots a_ma_m \text{ and}$$
$$a_1a_1 = \varepsilon^{2/3}/m \,.\, \varepsilon^{2/3}/m = \varepsilon^{4/3}/m^2;$$

when the Poiseuille coefficient is included the intrinsic permeability (K) is then given by:

$$K = \varepsilon^{4/3}m^{-2}\,[r_1^2 + 3r_2^2 \ldots\ldots (2m-1)\,r_m^2]/8 \quad (1)$$

The units of K are cm.² but for convenience in Figs. 1 and 2, K is expressed as μ^2.

For calculation of unsaturated permeability the value of ε adopted is that of the water-filled pore space and m remains constant. The r^2 series is commenced at the largest water-filled pore class. The basis for the variation of ε is due to changes in the water velocity which are not accounted for in the r^2 term of (1).

Figs. 1 and 2 enable a comparison to be made between the various methods for calculating permeability and the experimental results obtained by Childs and Collis-George for their 1 – ½ and ½ – ¼ mm. sands respectively. It can be seen from these figures that over a wide range of water content the curves calculated by the method herein proposed lie close to the experimental curves of permeability plotted against water content. The computed curves obtained either by the method of Childs and Collis-George (excluding M but including r and Poiseuille's 1/8) or by the method of Marshall are included for comparison; these latter curves clearly indicate that at high water contents the computed permeabilities are lower than those found experimentally.

Carman[4] has obtained the pore radius – volume curve for a Linde silica plug ($\varepsilon = 0{\cdot}506$); using these data and assuming an immobile monolayer the permeability of the plug has been calculated to be $2{\cdot}6 \times 10^{-15}$ cm.². This compares with the measured permeability[5] to CF_2Cl_2 at $-33{\cdot}1°$ C. of $3{\cdot}1 \times 10^{-15}$ cm.². It is interesting to note that the proposed

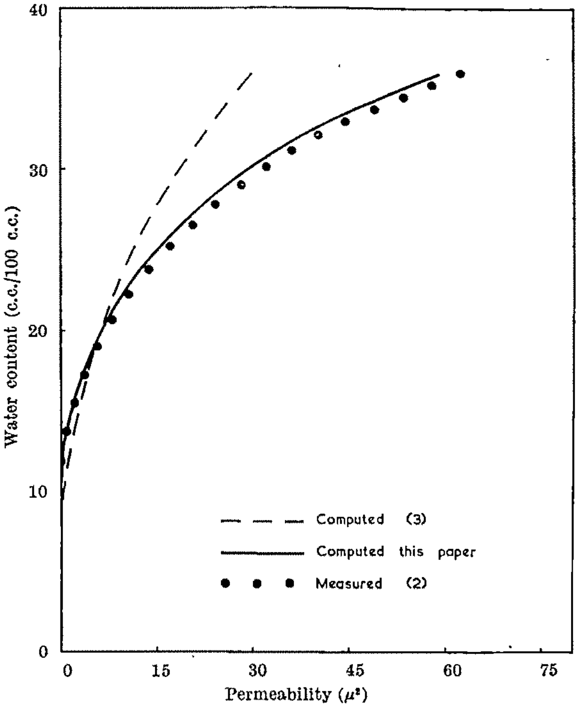

Fig. 2

equation for permeability calculation applies over a wide range of permeability, since the permeability of the Linde silica plug is almost 10^{-9} less than that for the 1 – ½ mm. sand.

A more extensive report of this work is being prepared for publication.

CHEMISTRY

Effect of Thermal Neutron Irradiation on Oxide Catalysts for the Decomposition of Nitrous Oxide

EFFECTS of radiation on catalysis have been investigated in various ways[1], including those of thermal neutron irradiation[2]. As thermal neutrons are of low energy, usually only a high flux density or a long exposure induces any change in catalytic activities. In this communication, however, we can report distinct effects on the catalytic activities of nickel oxide, aluminium oxide and stannic oxide used for the decomposition of nitrous oxide. The conditions were as follows: flux density, $10^{11}n$/cm.^{2}sec.; exposure time, 3 hr. With the aid of the (n, α) reaction of lithium-6 or boron-10 atoms, we may expect an intimate relationship between the catalytic activity and the lattice defects in the semi-conductor catalysts.

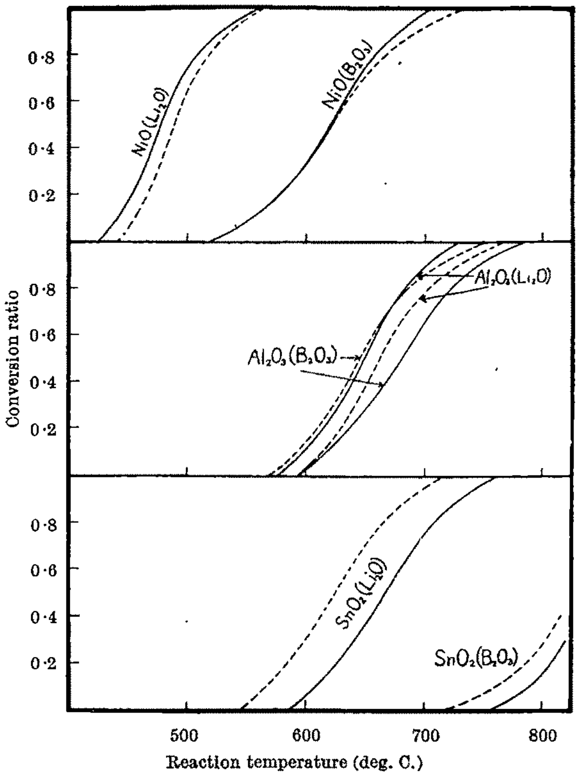

Fig. 1. Conversion ratio of nitrous oxide as a function of reaction temperature. The curves show the effect of thermal neutron irradiation on oxide catalysts. ——, Before irradiation; – – –, after irradiation

Separate samples of matrix powders of basic nickel carbonate, aluminium hydroxide and stannic hydroxide were dipped into aqueous solutions of lithium carbonate and boric acid, dried and fired at 750° C. for 2·5 hr. Lithium or boron atoms probably become distributed uniformly in matrices as oxides, the mixing ratio of atoms being 10 per cent, except for 1 per cent for lithium oxide in nickel oxide. The catalysts were irradiated in the *JRR*-1 nuclear reactor of the Japan Atomic Energy Research Institute at Tokaimura under the conditions mentioned above.

Table 1

Catalyst	NiO				Al_2O_3				SnO_2			
Addition Irradiation*	Li_2O bef.	 aft.	B_2O_3 bef.	 aft.	Li_2O bef.	 aft.	B_2O_3 bef.	 aft.	Li_2O bef.	 aft.	B_2O_3 bef.	 aft.
Frequency factor ratio	1·7	1	1·1	1	1·6	1	1	2·5	1	2·9	1	2·5
Apparent activation energy (kcal./mole)	22	23	19	19	23	23	23	24	21	20	43	30

* bef. and aft. refer to before and after irradiation, respectively.

The catalytic activity measurements were made one month later by a flow method. The conversion ratio as a function of the reaction temperature is shown in Fig. 1. Scarcely any induced radioactivity was detected : nickel oxide system, 0·2 mr./hr. (γ-rays) ; aluminium oxide system, none ; stannic oxide system, 0·4 mr./hr. (β-rays). On the assumption that the reaction is first-order, the apparent activation energy and the ratio of frequency factors before and after irradiation have been calculated and are shown in Table 1.

According to these results, the catalytic activity changes in every system : there is a small decrease with the nickel oxide system, an increase or decrease with the aluminium oxide system, and a remarkable increase with the stannic oxide system. Stannic oxide usually contains oxygen ion vacancies as an *n*-type semiconductor, and the number of these is readily increased by irradiation with alpha-particles which are produced by an (*n*, α) reaction with lithium-6 or boron-10 atoms. Nickel oxide contains excess oxygen ions as a *p*-type semiconductor and probably loses some of these on irradiation. The behaviour of the aluminium oxide system is probably due to its being an insulator.

The results of these experiments show that the larger the number of lattice defects, the more active is the semiconductor catalyst.

A Simple Synthesis of Oxetanes

WE would like to report a simple method of synthesizing oxetanes. Oxetanes have generally been prepared by a multi-step procedure involving the basic elimination of a halide or acyl radical. The syntheses are involved, and yields are low to fair. Our methods consists of dissolving a diol in a mineral acid, introducing the mixture into a heated solution of base, and distilling off the cyclic ether produced.

Using this method, we have prepared oxetane, 1-methyl oxetane and 2,2-dimethyl oxetane. Indications are that this synthetic method is generally applicable to the preparation of cyclic ethers, including oxiranes. Further work using this method is in progress.

Preparation of 2,2-*dimethyl oxetane.* 2 moles of sulphuric acid (111 ml., 96 per cent) were added to 2 moles of neopentyl glycol (208 gm.) and the mixture was stirred. The resulting solution was very viscous. A solution of 240 gm. sodium hydroxide in 107 ml. of water was brought to the boiling point in a 1-l., 3-neck flask equipped with a stirrer, dropping funnel and distilling head. The glycol solution was then added from the dropping funnel at such a rate as to maintain boiling. About 30 min. was required for this addition. Some heating of the dropping funnel with a burner was required to keep the viscosity of the glycol solution low enough for an adequate rate of flow. 120 ml. of distillate was collected, which separated into two layers. The lower aqueous layer was separated and partially redistilled to recover the organic material. The organic layer from the partial redistillation was combined with the original organic layer and dried with calcium chloride. The dried organic layer was further dried with calcium hydride and distilled.

The product boiling between 79° and 83° C. amounted to 49·2 gm., or 29 per cent.

For further characterization, the product was again redistilled from calcium hydride. The fraction boiling between 79·2 and 80·3° C. (uncorrected) at a pressure of 756 mm. mercury was collected.

The density was found to be 0·8272 gm./ml. at 25° C. The refractive index, N_D(25·1° C.), was 1·3956.

An infra-red spectrum was obtained, and found to be identical to one previously published[1], except that there was no indication of either carbonyl or hydroxyl in our sample.

Cis–trans Isomerism of Thioindigo Dyes in the Solid State

As the result of some preliminary observations by Stearns[1], an extensive study was made by Wyman and Brode[2] of the absorption spectra of solutions of several thioindigo dyes in benzene and chloroform under various conditions of illumination. Evidence was obtained that in solution thioindigo and its derivatives exist in equilibrium as two forms (*cis* and *trans*), which give rise to separate absorption bands in the visible region. X-ray diffraction studies on crystalline thioindigo by Madame von Eller[3] suggest, however, that in the solid state the dye is present in the *trans* form. It is thought that the electrostatic attraction between slight positive and negative charges on neighbouring sulphur and oxygen atoms, respectively, maintains the thioindigo molecule in the *trans* configuration and prevents isomerization[4]. Presumably in some cases these attractive forces will be weakened by solvents or by substitution in the thioindigo molecule.

Some observations have recently been made of the absorption spectra of several thioindigo compounds in the form of solid transparent films on quartz prepared by vacuum deposition. The results suggest that where substitution would not be expected to diminish the electrostatic charges on the sulphur and oxygen atoms the *trans* compound appears to be the stable form in the solid state ; but where reduction of these charges would be expected a mixture of *cis* and *trans* forms is found. Thus, as is seen in Fig. 1, solid films of thioindigo and 6 : 6′ dichlorothioindigo both exhibit a sharp absorption band in the visible region indicative of the sole presence of the *trans* isomer in the solid state. The presence of chlorine atoms in the 6 and 6′ positions in the thioindigo molecule should increase the negative character of the oxygen atom, and thus enhance the stability of the *trans* form. The introduction of methyl groups into the 4 and 4′ positions of this derivative of thio-

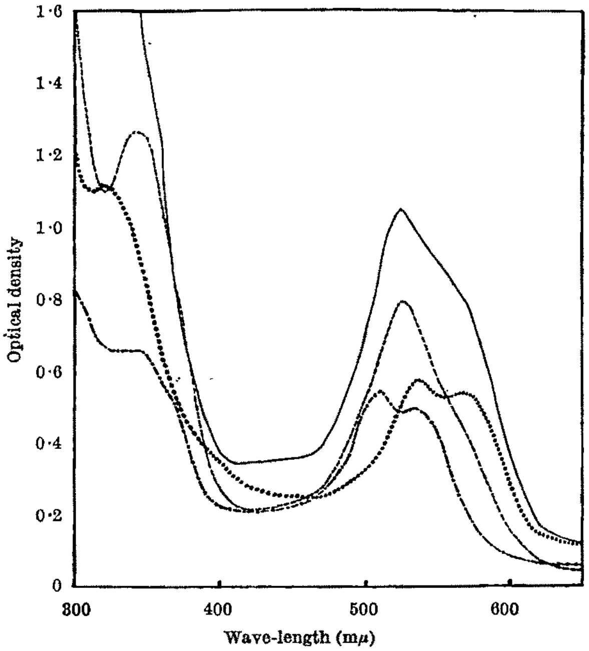

Fig. 1. The absorption spectra of solid films on quartz of thioindigo, ———; 6 : 6′ dichlorothioindigo, – – – – –; 4 : 4′ dimethyl 6 : 6′ dichlorothioindigo, –·–·–·–; and 5 : 5′ dichloro 7 : 7′ dimethylthioindigo, ·······

indigo will, however, tend to reduce the electrostatic charge on these atoms and as might therefore be anticipated 4 : 4′ dimethyl 6 : 6′ dichlorothioindigo exists in the solid state as a mixture of *cis* and *trans* forms. A similar result is found with 5 : 5′ dichloro 7 : 7′ dimethylthioindigo. The proportion of *cis* form appears to be substantially in excess with the unsymmetrical 4 : 4′ dimethyl 5 : 6′ : 7 trichlorothioindigo, which is not illustrated in Fig. 1. It is also interesting to compare the spectrum of 6 : 6′ diethoxythioindigo with the analogous chlorine derivative. The former compound containing the electron-donating ethoxy group appears to exist as a mixture of *cis* and *trans* forms in the solid state, whereas the presence of the electron-attracting chlorine atom in 6 : 6′ dichlorothioindigo favours the stabilization of the *trans* form. Comparison of the hemithioindigo dye, 1′ acenaphthene 2 thianaphthene indigo with thioindigo is also valuable. The *trans* form of the latter has two pairs of sulphur and oxygen atoms available for stabilization, whereas the former has only one. The hemithioindigo dye[5] exists in the solid state as a mixture in which the *trans* form predominates.

When the thioindigo dyes are applied to cellulosic materials from solution in an alkaline reducing agent the leuco dye absorbed on the cellulose is incapable of existing in *cis* and *trans* forms because of the single-bond character of the central carbon atom. On oxidation of the dyeing the central double bond is reformed and isomerization of the dye is possible. Measurements of the absorption spectra of such dyeings on transparent cellulose film (deplasticized) have been made. The spectra of dyeings of thioindigo and 6 : 6′ dichlorothioindigo indicate only the presence of the *trans* form, whereas other substituted derivatives appear to be present in the dyed material in both *cis* and *trans* forms. In some cases (for example, 1′ acenaphthene 2 thianaphthene indigo[5] and 4 : 4′ dimethyl 6 : 6′ dichlorothioindigo) it is possible to increase the proportion of the *trans* form in the dyed cellulose by giving the latter a swelling treatment (for example, boiling with dilute soap solution), but in other cases (for example, 5 : 5′ dichloro 7 : 7′ dimethyl thioindigo and 4 : 4′ dimethyl 5 : 6′ : 7 trichloro thioindigo) the *cis* form seems remarkably stable to treatments of this kind. In both cases, however, the tendency is for the absorption spectrum of the after-treated dyeing to be very similar to that of the solid film of the same dye prepared by vacuum deposition. It would seem that many of the thioindigo dyes are present in a fairly stable mixture of *cis* and *trans* forms under the conditions of their commercial utilization.

Crystal Structure of β-Glycine

It has been reported that glycine has three polymorphic forms: (1) an ordinary form, α, the crystal structure of which was determined in 1939 by Albrecht and Corey[1], a precise analysis having recently been carried out by Marsh[2]; (2) an unstable form β, first described by Fischer[3]—Bernal[4] has reported preliminary results of X-ray investigations of unit cell dimensions and space group symmetry, but the results are not conclusive; (3) the third form γ, found by me[5] in 1954, the crystal structure of which has recently been determined[6]. In this connexion, it seemed worth while to investigate the crystal structure of the β-form so that a comparison might be made between these three crystalline forms, especially of their hydrogen-bond systems.

A brief account of the structural determination will be given: the cell dimensions and space group

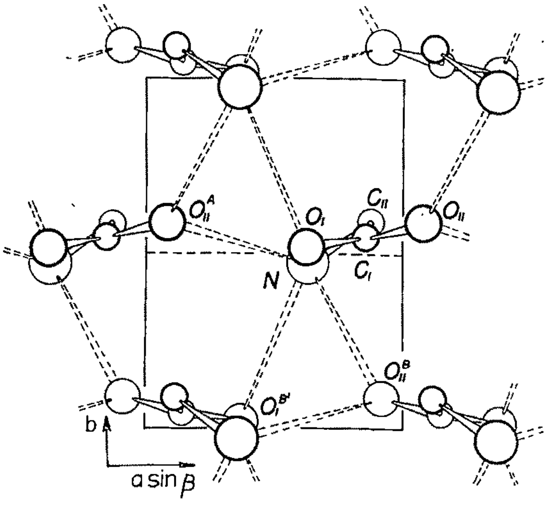

Fig. 1. A view of the β-glycine structure parallel to the *c*-axis, showing molecular layers connected by hydrogen bonds extending in the *b*-direction. Double dashed lines indicate hydrogen bonds

Table 1. COMPARISON OF THE CELL DIMENSIONS AND SPACE GROUPS OF α-, β- AND γ-GLYCINE

Form	Cell size (A.)					Space group	No. of molecules per cell	Molecular volume (A.³)
	a	b	c	β	Volume			
α*	$5{\cdot}102_0$	$11{\cdot}970_9$	$5{\cdot}457_5$	111° 42·3′	309·7	$P2_1/n$	4	77·4
β	$5{\cdot}077_4$	$6{\cdot}267_8$	$5{\cdot}379_9$	113° 12′	157·4	$P2_1$	2	78·7
γ†	7·037		5·483		235·1	$P3_1$ or $P3_2$	3	78·4

* See ref. 2. † See ref. 6.

are shown in Table 1 together with those of α- and γ-glycine.

Intensities were recorded using a single-crystal diffractometer[7]. A trial structure similar to that of α-glycine was adopted. Refinement of the structure was carried out using both (*h0l*) and (*0kl*) difference Fourier projections. The (*0kl*) difference map gave clear indication of the anisotropic thermal motions of the atoms along the *b*-axis. Taking into account these anisotropies, the structure was further refined. The resulting reliability factors were 0·06 and 0·05 for (*h0l*) and (*0kl*) reflexions, including contributions from hydrogen atoms.

The arrangement of the molecules of glycine in the β-form is indicated in Fig. 1, which shows that it consists of hydrogen-bonded molecular layers extending parallel to the (010) plane. These layers have the same configuration of molecules as the α-form.

It is of interest to compare the packing of these layers in the two types of glycine. These forms differ in the hydrogen-bond systems between layers. In β-glycine, those single layers connected geometrically by the two-fold screw axis are held together by hydrogen bonds extending in the *b*-direction. In α-glycine the nitrogen atom is buried within the double layer in such a way that very close contact of these two layers occurs.

The values for the bond-lengths and bond-angles of the molecule are very close to those found in the α-form. However, the departure of the nitrogen atom from the plane containing the carboxyl group by 0·59 A. is somewhat larger. In Table 2 the bond-lengths and bond-angles are given together with N..O interatomic distances and C—N..O angles between neighbouring molecules.

Table 2. BOND-LENGTHS AND BOND-ANGLES IN β-GLYCINE

Length (A.)	Angle (deg.)	Length (A.)	Angle (deg.)

Circular Gas Chromatograph

IT is reasonable that a gas chromatographic apparatus can be arranged in a circular form. Fig. 1 shows a chromatographic column connected head to tail. In operation, the carrier gas is brought to a desired initial pressure using the stopcock arrangement that is also utilized for sampling. The pump in the circuit is used to circulate the carrier gas previously introduced. Simple laboratory peristaltic-type pumps have been found satisfactory for circulating the gas stream. A bleed stream of carrier gas from a separate source is used in the reference side of a resistance-wire thermal-conductivity detector. The columns are packed with crushed insulating brick of conventional size. Temperature control is accomplished by either liquid or air baths.

The stationary liquid phase normally used in gas chromatography has a low volatility relative to the compounds being separated. With the circular apparatus, the liquid need not have a low volatility. Fig. 2 shows the record for separation at room temperature of acetone, boiling point 56·2° C., and normal hexane, boiling point 68·7° C., using methanol, boiling point 64·7° C., as the liquid phase. Acetone travels more slowly than hexane due to selective adsorption and is separated after passage through half the circular column. During the time required for acetone to make an additional circuit of the column, the hexane has gone through the detector two additional times.

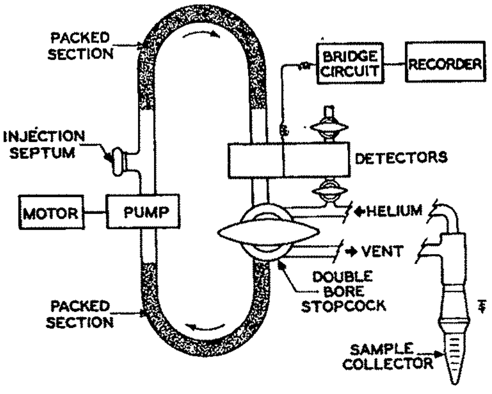

Fig. 1. Schematic diagram of circular gas chromatograph

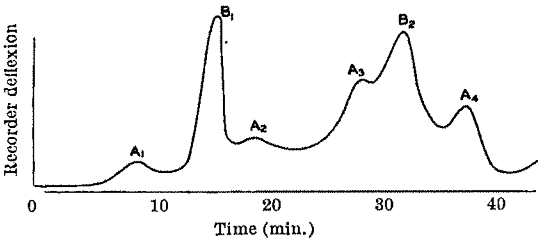

Fig. 2. Injection of a mixture of *A*, *n*-hexane, and *B*, acetone, using a methanol column

In a separate experiment, the retention time of normal heptane is 4·5 min. for the solid support coated with methanol and 0·5 min. for the support with no liquid present under the same conditions. Therefore, the methanol clearly is acting as a partitioning liquid.

There are several advantages in being able to use volatile partitioning liquids. A wider range of liquids can be utilized. In addition, non-analytical chromatographic applications are often of more interest if there is less difference in the boiling points of the liquid phase and the partitioned components. Experimentally, volatile partitioning liquids can be added through the sample injection septum and allowed to become distributed uniformly *in situ*.

The dead volume in the detector cell and mixing action of the pump cause a loss in efficiency as compared to a single pass through a comparable straight column. Column efficiency is evaluated by conventional theoretical plate calculations. However, using 2,4-dimethylsulpholane as the liquid phase in a circular 10-ft. column, the efficiency was found to increase linearly with the number of cycles up to a length of column equivalent to 150 ft. This arrangement, therefore, offers a way to operate the equivalent of a long column at a low and more efficient ratio of the initial pressure to that at the outlet.

On a preparatory scale, use of the circular arrangement conserves solid support, liquid phase, carrier gas, and the energy required for thermostatic control. The optimum length of column for separation can be selected by choosing the proper number of cycles the materials are circulated. The equipment can be made automatic.

Starch Gel Electrophoresis Studies on Abnormal Proteins in Myeloma and Macroglobulinæmia

We have investigated by starch gel electrophoresis[1], using a technique described in a previous paper[2], 28 sera from patients with multiple myeloma, 13 from patients with macroglobulinæmia, 4 sera from cases with atypical dysproteinæmia. In every case a characterization of abnormal serum components was carried out previously, using free-boundary electrophoresis[3], analytical ultracentrifuging[4], agar gel and immuno-electrophoresis[5].

Concerning plasmocytoma, in so-called 'γ-myeloma' (according to free-boundary electrophoresis at *p*H 8·6, ionic strength 0·1 in veronal buffer), the sera demonstrated in starch gel either a high 'fast' or a high 'slow-γ' component. On sedimentation diagrams, a 6 *S* component was seen in most cases.

In cases of 'β-myeloma' in starch gel, abnormal components, as shown by quantitative results, are located in various positions, but in the α-β and slow-α 2 zone.

In a typical β-myeloma, starch gel electrophoresis shows three abnormal components (as compared with normal serum). The euglobulinic fraction of the serum similarly shows three components. In one case of α-myeloma the abnormal component is in the post-albumin zone.

Concerning macroglobulinæmia, sera with high levels of heavy components (mainly 17 *S*), ascertained as β-2 *M* globulins by immuno-electrophoresis, yield, in starch gel, no characteristic patterns. That may be due (Silbermann, H. J., personal communication) to the non-displacement of macroglobulins in the gel.

Four cases of 'dysproteinæmia were selected from 136 patients with 'myeloma-like' patterns. These cases are characterized by the absence of bone marrow plasmocytosis, negativity of X-ray investigations, but β-2 *M* globulins and/or heavy components (by sedimentation) were lacking. Electrophoretic pattern in starch gel resembles that of myeloma.

The influence of size of molecule may be emphasized in the case of β-lipoprotein in starch gel[6].

In the present study some findings seem to be related to the same phenomenon; for example, an abnormal α-component (mobility 4 cm.^{2}/volt/sec. 10^{-5} at *p*H 8·6) shows in starch gel an increase in the post-albumin zone, and 92 per cent of the serum components migrated as light components by ultracentrifugating the (4 *S*) component.

In conclusion, we feel that investigation of dysproteinæmias using electrophoresis in starch gel may be a very promising subject.

The Iron-Protein Link in Hæmoglobin and Myoglobin

It is generally considered that the hæm iron in hæmoglobin and myoglobin and their derivatives is bound to the apoprotein through histidine imidazole groups, although there is some uncertainty[1] whether the stronger of the two postulated imidazoles (ascribed $pK_1 = 5 \cdot 3$ in ferrihæmoglobin and ferrimyoglobin[2]) has been so identified.

The *p*H stability curves of native and recombined horse ferrimyoglobin are shown in Fig. 1, obtained after addition of solutions of the native protein and of the components of the recombined protein to a series of phthalate and phosphate buffers (*p*H 2·3–7·0, $\mu = 0 \cdot 05$, $T = 21°$ C.). The solutions were stood for 16 hr. at 1° and then 2 hr. at 21° before reading the absorbances at 408·5 mμ, the Soret *p*H 7·0 peak. Curves of similar type and approximate position were obtained for ferrihæmoglobin, measured at 405 mμ. When hæmatin or ætiohæmatin combines with native globin or apomyoglobin at *p*H 6–7, a comparable major increase in Soret peak absorbance occurs[3] between *p*H 4 and 6 (Fig. 1). The curves therefore appear to indicate dissociation of the hæmatin iron from specific groups in the apoprotein.

A reversible equilibrium between 'acid hæmatin' and ferrihæmoglobin exists[4] within the *p*H range 3·0–6·0, and while the curves of Fig. 1 and similar ones obtained by removal of hæmatin with acetone[5] do not exactly fit dissociation curves of acids with single equilibrium constants, they could represent such curves partly masked by overlapping contributions from other linkages, such as hæmatin propionyl – apoprotein or iron – anion ligand.

Since at *p*H 5·3 only a very small decrease in Soret peak absorbance occurs and only a very small fraction of the hæmatin is extracted by acetone[5], the specific groups indicated, which I consider to be those binding the hæmatin iron to the apoprotein, are unlikely to be the postulated imidazoles of $pK_1 = 5 \cdot 3$. A *pK* of this value could be related to dissociation of hæmatin propionyl. Rather it would appear that groups of the nature of aspartyl β- or glutamyl γ-carboxyls ($pK \approx 4 \cdot 7$) are ionizing. Potentiometric titration studies of horse carboxyhæmoglobin[6] have also suggested carboxyl groups (of *pK* approximately this value) linked to the hæm, while iron–carboxyl linkages have been considered to occur in recombined hæmoglobin[1] and, on evidence from both spectrophotometric and enzymatic activity studies, in the related hæmoprotein, horse-radish peroxidase[7].

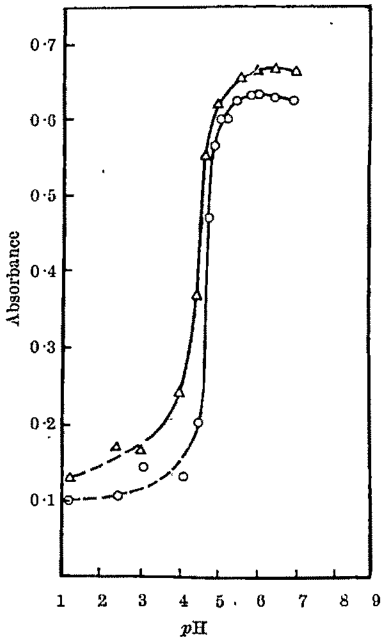

Fig. 1. *p*H stability curves of native and recombined horse ferrimyoglobin in the *p*H range 1–7 from the absorbances at 408·5 mμ. Native ferrimyoglobin (—○—○—), 0·1 ml. $9 \cdot 3 \times 10^{-5}$ *M* solution + 10 ml. buffer; recombined ferrimyoglobin (—△—△—), 0·05 ml. $1 \cdot 8 \times 10^{-4}$ *M* protohæmatin in 0·01 *M* sodium hydroxide + 0·10 ml. $2 \cdot 1 \times 10^{-4}$ *M* apomyoglobin solution + 10 ml. buffer. Buffers: *p*H 1·2, hydrochloric acid; 2·3–6·2, phthalate; 6·5–7·0 phosphate; $\mu = 0 \cdot 05$. Temperature of measurement, 21° C. Path-length, 4 cm.

Chromatographic Behaviour of Human Albumin labelled with Iodine-131

The *in vivo* behaviour of plasma proteins labelled with iodine-131 prepared by methods developed in this laboratory[1,2] is almost identical with that of the corresponding proteins labelled with carbon-14 by the biosynthetic procedure[3,4]. Human albumin preparations iodinated by these methods have a chromatographic distribution similar to that of unlabelled albumin when analysed on anion exchange columns of diethylaminoethyl cellulose (Fig. 1). Similar results have been obtained on cation exchange columns of carboxymethyl cellulose. On the other hand, commercially iodinated human albumin (Abbotts, Chicago), which has been extensively used in clinical studies of albumin turnover, has recently been shown to have a chromatographic distribution markedly different from native albumin[5]. It is now recognized that preparations of protein labelled with iodine-131 may be adversely affected by a variety of factors, including the method of fractionation, the technique of iodination[1], preliminary heat treatment of the protein[6] and self-irradiation[7]. Investigation of these variables has shown that by far the greatest changes in chromatographic behaviour of albumin labelled with iodine-131 result from self-irradiation.

Human albumin prepared by ion exchange chromatography[8] was iodinated at a mean ratio of less than 1 atom per molecule using the iodine monochloride method recently described by McFarlane[2]. The effect of self-irradiation was investigated in solutions containing 2–3 mgm. albumin and 500–700 μc. of iodine-131 per ml. Solutions were stored at 3° C. and tracer amounts added to human serum at intervals after labelling. Irradiation-levels between 40 and 85 k.rads produced a progressive displacement of the radioactive from the native albumin (Fig. 2). The electrophoretic mobility on paper of these irradi-

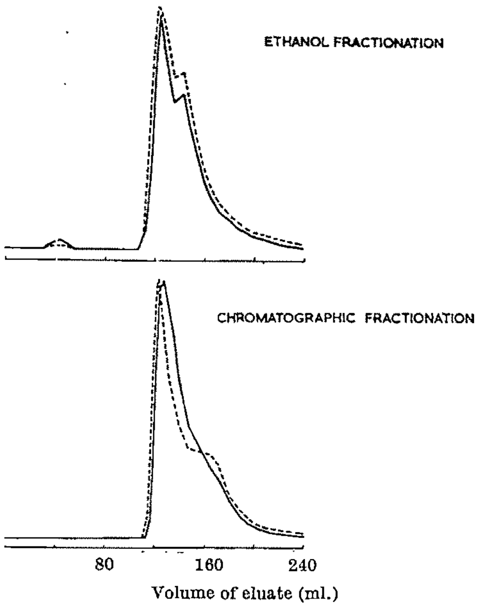

Fig. 1. Chromatographic analysis of human albumin prepared by ethanol fractionation and ion exchange chromatography. Iodinated albumin (0·5 mgm.) was added to 50 mgm. of the corresponding unlabelled albumin before dialysis. The analysis was performed on diethylaminoethyl cellulose columns using a gradient elution with phosphate buffer *p*H 7·1, 0·005 *M* and 0·30 *M* sodium dihydrogen phosphate. Protein distribution is indicated by solid lines and radioactivity by broken lines

ated proteins remained unchanged although as previously shown[7] albumin 'tailing' was increased by irradiation at doses above 45 k.rads.

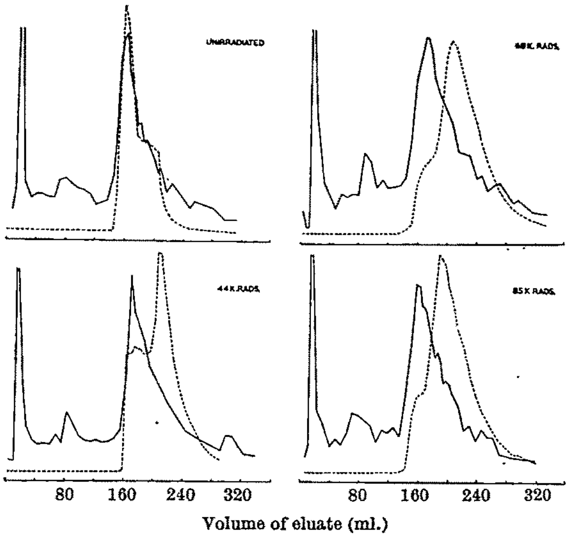

Fig. 2. Effect of irradiation on the chromatographic behaviour of human albumin labelled with iodine-131 and prepared by chromatography. Tracer amounts of the labelled solution which contained 650 μc. iodine-131 per ml. and 2·5 mgm. albumin per ml. were added to normal human serum immediately after iodination and after storage for 7, 14 and 22 days, which provided self-irradiation doses of 44 k.rads., 68 k.rads, and 85 k.rads respectively. Chromatography was carried out as in Fig. 1. Protein distribution is indicated by solid lines and radioactivity by broken lines

In contrast to the marked effect of irradiation only minor differences in chromatographic behaviour were induced by altering the methods of albumin fractionation and iodination. Human albumins prepared by zone electrophoresis, ion exchange chromatography, ethanol fractionation[9] and crystallization from concentrated salt solution (Behringwerke, Marburg-Lahn) were examined. After iodination[2] these proteins were added to the corresponding unlabelled albumin so that labelled molecules constituted not more than 1 per cent of the protein analysed. The various albumin preparations were not chromatographically identical, but in all of them the distribution of labelled and unlabelled molecules was similar. Results obtained with two of these preparations are shown in Fig. 1. Albumin iodinated using hypochlorite[10] showed a second minor peak of radioactivity displaced beyond the native albumin. Preliminary heat treatment of human albumin in the presence of stabilizers did not alter the chromatographic pattern.

It is concluded that human albumin can be prepared and iodinated without gross alteration of its behaviour on the ion exchange columns used in this investigation. Similar results have been obtained with rat and rabbit albumins. The chromatographic dissociation of native human albumin and that labelled with iodine-131 recently reported[6] can be reproduced in dilute protein solutions by self-irradiation at levels above 40 k.rads. Chromatographic analysis appears to be the most sensitive physicochemical method available for detecting undesirable alterations in samples of albumin labelled with iodine-131 for metabolic studies.

I am grateful for helpful discussions with Dr. A. S. McFarlane and Dr. R. R. Porter. Dr. P. S. Charlwood and Prof. H. E. Schultze kindly supplied samples of human albumin.

1,6-Di-(2-Bromoethylamino)-1,6-Dideoxy-D-Mannitol Dihydrobromide: a New Cytostatic Agent

RECENTLY it was reported that 1,6-di-(2-chloroethylamino)-1,6-dideoxy-D-mannitol dihydrochloride[1] shows significant tumour inhibitory effect[2]. This compound ('Degranol', 'Mannomustine') has been employed in the treatment of malignant hæmatological diseases[3].

Since the chlorine atoms of this compound show comparatively slight reactivity, and since the cytostatic effect in the group of mustard nitrogen derivatives increases in general parallel to the reactivity of halogen atoms of the 2-halogenethylamino group[4], in further experiments we replaced the chlorine atoms of 1,6-di-(2-chloroethylamino)-1,6-dideoxy-D-mannitol dihydrochloride with the more active bromine atoms. The synthesis of this bromine derivative (1,6-di-(2-bromoethylamino)-1,6-dideoxy-D-mannitol dihydrobromide) was performed by analogy with the (1,6-di-(2-chloroethylamino)-1,6-dideoxy-D-mannitol dihydrochloride from the 1,6-diethylenimino-1,6-dideoxy-3,4-*iso*propylidene-D-mannitol with concentrated aqueous hydrobromic acid. The former compound crystallizes from *iso*propanol, or aqueous dioxan in colourless needles which are easily soluble in water: m.p. 204–205° C. while decomposing; $[\alpha]_D^{20} = + 10\cdot6°$, water, $c = 1\cdot0$. (Found: C 21·4, H 4·6, Br 57·4. $C_{10}H_{24}O_4N_2Br_4$ requires C 21·6, H 4·4, Br 57·5.)

As animal experiments presented in the next communication prove, 1,6-di-(2-bromoethylamino)-1,6-dideoxy-D-mannitol dihydrobromide is active as expected in much smaller dose than the chlorine derivative and its therapeutic effectiveness is more favourable.

Effect of 1,6-Di-(2-Bromoethylamino)-1,6-Dideoxy-D-Mannitol Dihydrobromide on Tumours of Laboratory Animals

The chemotherapeutic effect of the new compound 1,6-di-(2-bromoethylamino)-1,6-dideoxy-D-mannitol dihydrobromide (see preceding communication) has been tested on different tumours of laboratory animals (Table 1). The compound was administered once daily in succession intraperitoneally after the appearance of palpable inoculated tumours. In comparison we tested the effect of the chlorine derivative ('Degranol', 'Mannomustine')[1] in the treatment of the same tumours.

From the results it is obvious that the 1,6-di-(2-bromoethylamino)-1,6-dideoxy-D-mannitol dihydrobromide inhibits the growth of rat and mouse tumours to a greater extent than 'Degranol' (Fig. 1).

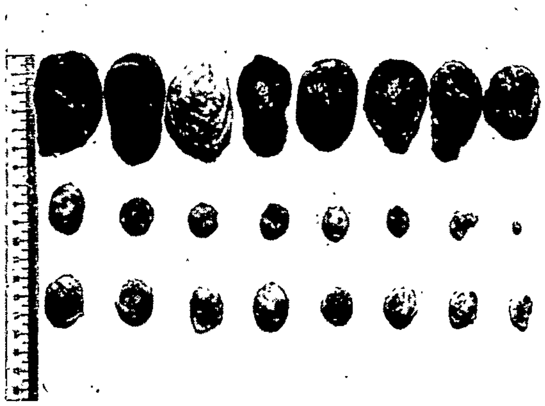

Fig. 1. Inhibition of the growth of the subcutaneous form of Yoshida sarcoma by 1,6-di-(2-bromoethylamino)-1,6-dideoxy-D-mannitol dihydrobromide (DBM) (*R*/13) and the chloride derivative (BCM)

Top, control; middle, DBM; bottom, BCM

Table 1. Degree of Inhibition of the Growth of Rat and Mouse Tumours by 1,6-Di-(2-bromoethylamino)-1,6-dideoxy-D-mannitol Dihydrobromide (DBM) (*R* 13) and the Chloride Derivative (BCM) ('Degranol')

Tumours tested	Degree of inhibition (per cent) DBM (*R* 13)	BCM ('Degranol')
Guérin rat carcinoma	89	
Guérin rat carcinoma	64	54
Yoshida rat sarcoma subcutaneous form	93	84
Ehrlich mouse carcinoma	39	21
S_{37} mouse sarcoma	53	29
Amytal mouse ascites (ref. 2) sarcoma	44	19

For the treatment of mice with tumours, 3–5 mgm./kgm. daily dose is necessary, and for the treatment of tumour-bearing rats 2–3 mgm./kgm. is sufficient. In contrast, the daily therapeutic dose of 'Degranol' corresponds to 20 mgm./kgm. for mice and 15 mgm./kgm. for rats.

When given 34 times in daily succession, the therapeutic dose to rats, in the bone marrow a slight decrease of leucopoietic elements is to be observed. Study of the blood reveals moderate leucopænia with more marked lymphopænia. Microscopically, in the spleen and lymph nodes atrophy of the follicles can be found.

Biochemical Heterogeneity of the Ribonucleic Acid synthesized by *Escherichia coli B* after Irradiation with Ultra-violet Light

It is well known that the effects of radiation on the biosynthesis of ribonucleic acid and protein are reduced slightly under conditions in which the synthesis of deoxyribonucleic acid is inhibited almost completely[1]. There have been few investigations of the ribonucleic acid synthesized after irradiation.

It has recently been suggested by Haas and Doudney[2,3], however, that mutation of *Escherichia coli* is induced by ultra-violet light through the incorporation of modified nucleic acid precursors into the ribonucleic acid, resulting in modifications of the latter. It is thus of interest to investigate whether any chemical or biochemical modifications occur in ribonucleic acid synthesized after irradiation.

An overnight culture of *E. coli B*(*H*) was inoculated in *tris*–glucose medium and harvested by centrifugation when growth was in the logarithmic phase. The cells collected were washed once with physiological saline and resuspended in the same saline. Half the suspension was irradiated with ultra-violet light. Irradiation was carried out by germicidal lamp ('Toshiba' *GL*-1502, 15 W.) for 60 sec. at a distance of 30 cm. The other half was used, unirradiated, as control. Both irradiated and control cells were collected and resuspended in *tris*–glucose medium

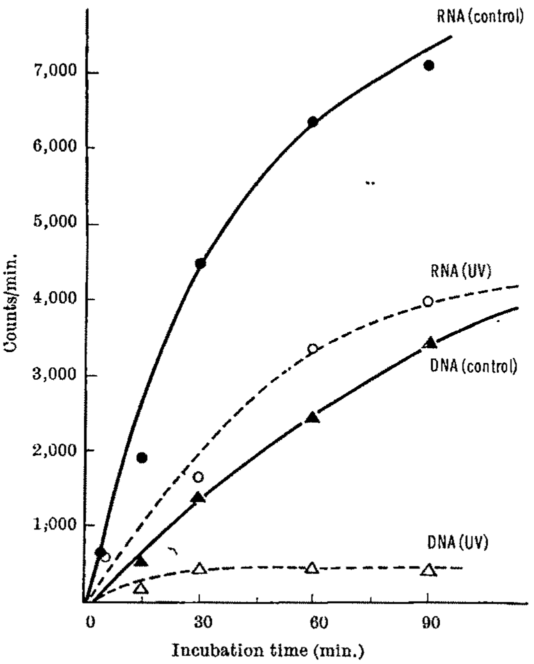

Fig. 1. The incorporation of phosphorus-32 into the ribonucleic acid and deoxyribonucleic acid fractions of *Escherichia coli B*(*H*), with and without irradiation with ultra-violet

containing phosphorus-32 and incubated at 37° C. From time to time samples were withdrawn and the phosphorus-32 incorporated was fractionated by the procedure of Schmidt and Thannhauser. The incorporation of phosphorus-32 into the ribonucleic acid and deoxyribonucleic acid fractions after irradiation with ultra-violet is shown in Fig. 1. The survivals were about 10^{-5}, and the total amount of phosphorus-32 incorporated into the ribonucleic acid fraction was about 50 per cent after 60 min. as compared to the control. Inhibition of incorporation of phosphorus-32 into the deoxyribonucleic acid fraction was nearly complete.

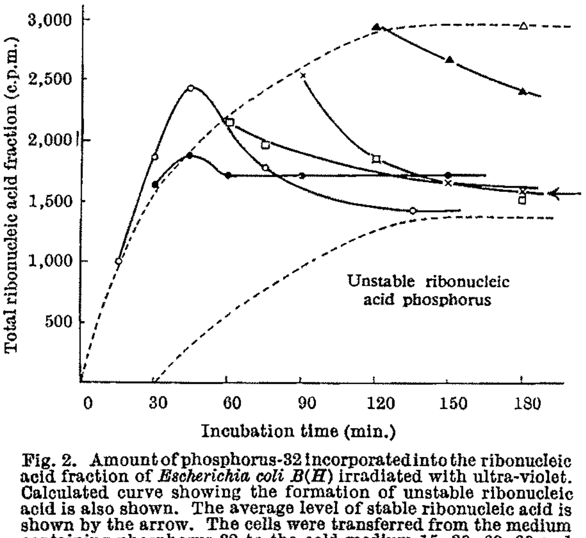

Fig. 2. Amount of phosphorus-32 incorporated into the ribonucleic acid fraction of *Escherichia coli B*(*H*) irradiated with ultra-violet. Calculated curve showing the formation of unstable ribonucleic acid is also shown. The average level of stable ribonucleic acid is shown by the arrow. The cells were transferred from the medium containing phosphorus-32 to the cold medium 15, 30, 60, 90 and 120 min. after the post-irradiation incubation; curves on symbols: ○, ●, □, ×, ▲ show the fate of phosphorus-32 incorporated into ribonucleic acid fractions during these periods respectively

Fig. 2 shows the phosphorus-32 incorporated in the ribonucleic acid fraction after the cells were removed from the medium containing phosphorus-32 at various times, washed, and reincubated in *tris*–glucose medium which contained no phosphorus-32.

Part of the phosphorus-32 incorporated into the ribonucleic acid fraction for incubation periods longer than about 30 min. has a tendency to be released from that fraction during re-incubation. But as shown in Fig. 2, the final level of phosphorus-32 in ribonucleic acid remains nearly constant regardless of the time when the cells are transferred to the isotope-free medium. When incubation with phosphorus-32 is shorter than 30 min., the amount incorporated reaches the final level described above and is conserved thereafter.

Ribonucleic acid phosphorus was conserved in unirradiated control cells as reported previously[4].

These results suggest that although the incorporation of phosphorus-32 into the ribonucleic acid fraction may occur in *E. coli* after irradiation with ultra-violet light, the fraction is composed of two parts, one stable and the other unstable. In addition, the incorporation into the unstable fraction seems to occur after a time-lag of 30 min. following irradiation (calculated curve is shown in Fig. 2). Since such a loss of phosphorus-32 from the ribonucleic acid fraction was not observed when the cells were incubated in the medium containing phosphorus-32 for 3 hr. after irradiation, and since the incorporation of phosphorus-32 was observed even when the isotope was added after incubation for 2 hr., the phosphorus in the unstable ribonucleic acid fraction seemed to be characterized by its continuous replacement.

The formation of unstable ribonucleic acid has been reported in some cases[5,6] and the degradation of these ribonucleic acids was found to be restored by the addition of chloramphenicol. The effects of the addition of chloramphenicol (40 μgm. per ml.) and dinitrophenol (10^{-3} *M*) and that of the omission of glucose from the medium were tested in our system but none of these agents was observed to have any effect on the loss of ribonucleic acid phosphorus.

The chemical difference between normal ribonucleic acid and that synthesized after irradiation with ultra-violet light is now under investigation, and a detailed report will be published elsewhere.

We wish to thank Mr. M. Izawa, chief of the Chemistry Division of the National Institute of Radiological Sciences, for his encouragement, and Prof. I. Watanabe and his colleagues of the Department of Biochemistry in the University of Tokyo for their gift of the bacterial strain and helpful discussions.

Activation of Amino-Acids in Relation to the Synthesis of Silk Proteins

THE 'activation' of the carboxyl groups in amino-acids is often assumed to be an indispensable preliminary stage in the biosynthesis of protein. The rate of the activation is known to vary with various amino-acids. The question arises whether there is any relation between the rate of activation of an amino-acid and its content in the protein. The silk-glands of the silkworm lend themselves particularly well to the study of such a problem since they produce two well-defined proteins, the amino-acid composition of which is known. While the posterior silk-gland produces 'fibroin', which contains 42 per cent of glycine and 28 per cent of alanine, the middle silk-gland produces 'sericin' containing 30 per cent of serine[1]. We have studied the activation of a number of amino-acids present in these two proteins of the silkworm caterpillars (*Bombyx mori* L.). The '*p*H 5 enzymes' were obtained from the posterior and middle silk-glands as well as from the hæmolymph. The hydroxamic method was used to determine the rate of the activation of the carboxyl groups in the amino-acids. The composition of the enzymatic mixture was approximately the same as that referred to by Davie, Koningsberger and Lipmann[2]. The results which we obtained are given in Table 1.

Table 1. THE RATE OF THE AMINO-ACID ACTIVATION IN SILK-GLANDS AND IN THE HÆMOLYMPH OF SILKWORM CATERPILLARS. THE RESULTS ARE EXPRESSED AS MEANS WITH THE STANDARD DEVIATION OF THE MEAN

Amino-acids	μmole of hydroxamates/1 mgm. of protein/hr.		
	Posterior silk gland	Middle silk gland	Hæmolymph
Alanine	0·068 ± 0·03	0·088 ± 0·03	0·085 ± 0·04
Glycine	0·038 ± 0·00	0·073 ± 0·01	0·057 ± 0·02
Glutamic acid	0·031 ± 0·02	0·258 ± 0·07	0·105 ± 0·03
Histidine	0·098 ± 0·01	0·286 ± 0·15	0·060 ± 0·02
Serine	0·318 ± 0·05	0·168 ± 0·04	0·079 ± 0·02
Tryptophan	0·623 ± 0·10	0·406 ± 0·21	0·071 ± 0·03
Tyrosine	0·600 ± 0·19	0·370 ± 0·18	0·150 ± 0·06

The two amino-acids which showed the highest rate of activation were tryptophan and tyrosine. Yet it is known that there are only traces of tryptophan in the proteins of the silk. Glycine, on the other hand, showed the lowest rate of activation in spite of its high concentration in the silk proteins. Thus no relationship could be established between the rate of the activation of amino-acids as measured by the hydroxamic method and their actual concentration in the proteins. We then decided to investigate the possibility that the activation of glycine proceeds mainly through transacylation. In view of the high rate of activation of tryptophan and tyrosine it seemed that the active forms of these two amino-acids might participate in such a process. An attempt was therefore made to observe activation of glycine in the presence of either tryptophan or tyrosine. Chromatographic analysis of the mixtures, however, did not reveal the presence of any hydroxamic acids other than those of tryptophan or tyrosine. As regards the possibility that glycine activation occurs outside the silk-glands, we found that in the hæmolymph the activation is negligible. Thus the question as to how glycine is introduced in the course of silk protein synthesis still remains open. Our results, however, suggest that the incorporation of amino-acids into protein must occur by means other than the activation of the carboxyl groups.

A detailed report of this work will be published in the *Acta Biochimica Polonica*.

Casease in *Entamoeba histolytica*

CASEASE, the proteolytic, casein-hydrolysing enzyme, has been reported in many bacteria. It has not hitherto been detected in the protozoan, *Entamoeba histolytica*. In earlier studies, Nakamura[1] reported the absence of casease in certain strains of the amœbæ. It was thought that the failure to demonstrate the enzyme might have been due to the comparatively large amounts of casein in the assay plates. Therefore, the experiments were repeated using a modification of the same method but incorporating smaller concentrations of casein in the test plates.

The amœbæ were cultured in coagulated whole egg slants overlaid with Ringer–liver extract solutions. Cultures 72 hr. old were pooled and washed four times in saline solution. The supernatant from the final washing was also tested for enzymatic activity; any remaining associated bacteria from the amœba stock cultures would be contained in this supernatant. In addition, the associated bacteria were assayed for casease activity in the absence of the amœbæ.

The method consisted of placing large drops of material to be assayed on the surface of 1·0 per cent agar plates containing 0·2 per cent casein, incubating for 12 hr. at 20–25° C., and flooding the agar plates with a mercuric chloride–hydrochloric acid solution (a protein-precipitating agent). Clear areas in the opaque casein-agar plates indicated zones of casein hydrolysis.

Two strains of *E. histolytica* (large race *HUS*-105 and small race Washington) hydrolysed casein. However, the supernatant from the fourth washing and the cultures of the associated bacteria did not hydrolyse casein. The amœbic casease was destroyed by heating at 65° C. for 5 min. but not by a temperature of 55° C. for 5 min. The enzyme activity at varying *p*H values was studied, and it was found to be active between *p*H 5 and *p*H 8. Thus, another proteolytic enzyme is established in *E. histolytica*. These experiments on the proteolytic activity of the amœbæ[2–4] may eventually yield clues on the mechanisms of pathogenicity of this important parasite.

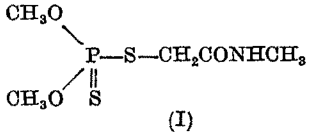
Mode of Action and Biological Properties of the S-(Methylcarbamyl) Methyl O,O-Dimethyl-Dithiophosphate

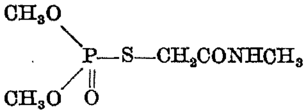
PREVIOUS investigations have demonstrated that S-(methylcarbamyl) methyl O,O-dimethyl-dithiophosphate (I), which possesses a peculiar insecticidal and systemic activity, very effectively controls the olive fly (*Dacus oleae* Gmel.)[1,2], the olive moth (*Prays oleellus* F.)[3], the cherry fruit fly (*Rhagoletis cerasi* L.)[4] and many other important pests. It was of interest, therefore, to investigate the metabolic behaviour and biological properties of this insecticide.

Experiments carried out by means of paper chromatography have demonstrated that oxidation of compound (I) by potassium permanganate and by hydrogen peroxide produces some derivates. Among them one component has been isolated, purified (by means of 100-tube Craig countercurrent distribution) and identified: the S-(methylcarbamyl) methyl O,O-dimethyl-thiolphosphate (II). The low R_F values of the spots and other evidence suggest that the other products of the oxidation of compound (I) are due to hydrolysis (possibly O,O-dimethyl dithio- and thiol-phosphoric acids). Metallic ions (Fe^{3+} Cu^{2+}, Zn^{2+}) catalyse the conversion of dithiophosphate (I) to thiolphosphate (II).



$$\mathrm{(CH_3O)_2P(=S)-S-CH_2CONHCH_3}$$

(I)



$$\mathrm{(CH_3O)_2P(=O)-S-CH_2CONHCH_3}$$

(II)

The same transformation has been shown to occur, at least partially, *in vivo* in plants such as broad beans, after root absorption of the insecticide, and in cherries, picked from sprayed trees; and *in vitro* in animal tissues, by incubating the insecticide (I) with mouse liver. Other derivatives (possibly products of hydrolysis), besides the thiol metabolite (II), from hydrogen peroxide oxidation of compound (I), were not found in the paper chromatographed tissues.

A gradual reduction in the amount of compound (II), obtained by chemical synthesis and applied to broad beans and cherries in the same conditions as insecticide (I), was demonstrated by paper chromatography and bioassay, but no evidence was obtained on the conversion of this compound to other derivates.

Toxicological researches indicate that the thiolphosphate (II) is a much stronger esterase inhibitor than the dithiophosphate (I): 185 times as effective as bovine cholinesterase inhibitor and 883 times as effective as house fly (*Musca domestica* L.) cholinesterase inhibitor. Nevertheless, compound (II) is only four times as toxic as (I) to mice by oral administration.

The insecticidal activity of both substances (I) and (II), tested on 11 species of insects, is nearly equal; the small differences being related to species and stages of insects and methods of testing. This suggests also that insects may metabolize the dithiophosphate (I) to thiolphosphate (II). On the other hand, the two substances possess different acaricidal activities: compound (II) is about 38 times as toxic as (I) to adults of *Paratetranychus pilosus* Can. and Fanz.

Finally, studies on systemic properties have been conducted. Both products, when applied to roots, stems or leaves of beans are absorbed and translocated to other parts of the plants in amounts lethal to the test mites (adults of *Tetranychus telarius* L.) feeding on untreated parts of the same plants. Furthermore, both compounds penetrate from the outside to the inside of fruits and exert a lethal effect on some species of fruit-eating larvæ.

Detailed results will be published elsewhere.

α-Tocopherol and Hyaluronidase *in vivo*

THE description of exudative diathesis in chicken by Dam[1] indicates a considerable degree of capillary damage. In a further publication[2] he attributed this to a deficiency of α-tocopherol.

Reports[3,4] on the interaction of α-tocopherol and hyaluronidase suggested to me that, apart from its anti-oxidant activity, α-tocopherol might be involved in the protection of inter-cellular cement substance. Thus, in the condition described by Dam, the exudation could be due to the effect of hyaluronidase acting on the inter-cellular cement substance of the capillary walls and surrounding supporting tissues without the restraining influence of adequate α-tocopherol.

We divided twelve chickens into three groups of four each. Group 1 was fed a basal ration low in vitamin E and containing 17 per cent protein, 3·3 per cent fat, 1·3 per cent calcium, 0·8 per cent phosphorus and 0·5 per cent added sodium chloride; group 2 received the same ration plus 14 I.U. vitamin E/lb. fed as added 'Rovimix' (F. Hoffman, La Roche et Cie.); group 3 a normal commercial ration. After 5 weeks on these diets two birds in each group were injected intraperitoneally with a commercial brand of hyaluronidase 'Rondase' (Evans Medical Supplies, Ltd.). Each bird received 6,000 I.U. daily for 7 days. On the eighth day the birds were killed together with the control uninoculated birds, and Table 1 shows the results of post-mortem examination.

Table 1

Group	Control birds (no hyaluronidase)	Birds injected with hyaluronidase
1	Slight hæmorrhages in muscles	Hæmorrhages and advanced exudative diathesis
2	Normal	Normal
3	Normal	Slight hæmorrhages in muscles

These results indicate that *in vivo* β-tocopherol can act as a regulator of hyaluronidase activity.

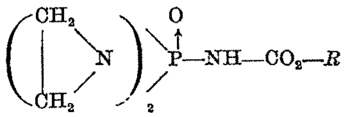
'Dual Antagonists'; Alkyl N-(*bis*-(ethylenimido)phosphoro)-carbamates; a New Series of Anti-Tumour Agents

THE concept of combination chemotherapy in the treatment of neoplastic diseases has been receiving considerable attention during the past few years. Some see the only theoretically possible solution to the problem of cancer chemotherapy in the simultaneous use of several synergistic drugs blocking several consecutive and/or alternative metabolic pathways, while others vigorously object to this thesis, from practical considerations or disappointing experiences.

One of our three collaborating research groups has been particularly interested in the chemotherapeutic potentialities of 'dual antagonists'[1], that is, chemical compounds incorporating the structural features of two different antimetabolites into a single molecule. 'Dual antagonists' are designed to synchronize the action of the synergistic components and thus overcome differences in absorption, distribution, or elimination that would negate or weaken any potentiation arising from simultaneous block of metabolic pathways at several points. If two inhibitors, directed against the same biochemical mechanisms or cellular structures but possessing different degrees of selectivity, are coupled chemically, the more selectively localizing component may prevail in directing the distribution of the molecule as a whole. As a result, the less selective (but often more potent) component may reach concentrations at the desired point of attack that could not be attained by the free (uncoupled) inhibitor below its toxic dosage. In particularly favourable cases, both synergistic components may be released at the desired point of attack gradually and simultaneously, providing for a prolonged local action.

Compound 1 of this communication unites the *bis*-(ethylenimido)-phosphoro radical, a bifunctional group known to have biological 'alkylating' activity, through an amide linkage to urethane, an antimetabolite of nucleic acid biosynthesis[2,3]. The carcinostatic effect of urethane is reported to be synergistic with the similar effect of biological alkylating agents[4].



1, $R = C_2H_5$ ('*AB*-100')
2, $R = CH_3$ ('*AB*-101')
3, $R = CH_2—C_6H_5$ ('*AB*-103')

In compounds 2 and 3, the same alkylating radical is linked to methyl and benzyl carbamate, respectively. Although the latter carbamates, as such, are not known to be effective antimetabolites, it is thought possible that when linked to the electron-attracting phosphoro-group they may split to yield the same active intermediate as urethane.

Compounds 1 and 2 were synthesized by treating dichloro*iso*cyanatophosphine oxide[5] first with ethyl alcohol (or methyl alcohol) and then with ethylenimine in the presence of a hydrogen chloride acceptor. Compound 3 was prepared by heating compound 1 in the presence of benzyl alcohol. All three compounds are white solids which can be crystallized from a mixture of benzene and cyclohexane: m.p.: 1, 88–90°; 2, 119–21°; 3, 134–35° C.

Compounds 1 and 2 are readily soluble in water, but decompose slowly in aqueous solution. In the animal experiments reported below, these two compounds were used in freshly prepared aqueous solutions, while compound 3 was injected in aqueous suspension or, intramuscularly, in peanut oil.

Acute intravenous toxicity tests in *ICR/Ha* Swiss mice gave the following *LD*50 values (mgm./kgm.): 1, 69·4; 2, 62·3; 3, 80·0. The corresponding values after intraperitoneal and subcutaneous administration are the same or only slightly higher, indicating rapid absorption. All deaths occurred between 4 and 9 days after the single injection. Histopathological studies indicated lymphoid involution.

Only a brief outline can be given here of the anti-tumour evaluation of compounds 1, 2 and 3; details will be published elsewhere. Eleven mouse and rat neoplasms were used in this work, and the new compounds were directly compared with nitrogen mustard under a variety of experimental conditions. In doses of equal toxicity, the three compounds were superior or equal to nitrogen mustard. In most cases, compound 3 demonstrated the highest activity, followed by compounds 1 and then 2.

In mice, all three compounds were active in the 'standard' sarcoma 180 test; average *T/C* ratios of 32 per cent by tumour diameter measurement, and 3–4 per cent (0·03–0·04) by tumour weight, were obtained. In different types of experiments with sarcoma 180, *ICR/Ha* Swiss mice were inoculated with known numbers of ascites tumour cells (*a*) subcutaneously and (*b*) intraperitoneally; in all experimental situations, the new compounds caused highly significant inhibitions of (*a*) tumour growth, and (*b*) ascites formation, respectively. Compounds 1 and 3 were also highly effective against Ehrlich ascites tumour and adenocarcinoma 755. In a number of transplanted leukæmias, definite prolongation of life was obtained with compounds 1 and 3; in others, prolongation of mean life-span was of borderline or no statistical significance. Many animals in the latter groups lived much longer than any untreated animals, but many died earlier, presumably because of drug toxicity in a state weakened by disease. This results in increased standard deviation. In *DBA*/2 mice inoculated with leukæmia *L*1210, four animals (out of 50) treated with compound 3 survived 90 days after inoculation and showed no sign of disease when killed and autopsied after this time. In our hands, no other chemotherapeutic agent produced similar apparent cures in any mice inoculated with this leukæmia. In *C3H* mice with 'spontaneous' mammary tumours, highly toxic doses of compound 3 (which actually killed all animals within 2 weeks) caused regression of existing tumours; lower, non-toxic doses inhibited tumour growth.

In rats, all three compounds completely inhibited the growth of Walker carcinosarcoma 256 tumours, at well-tolerated dosage-levels. In Dunning rat leukæmia, all three compounds, administered only during the first 12 days after implantation of the tumours, caused complete inhibition of tumour growth and apparently cured all animals. When they were re-inoculated with the tumour after 42 days, all developed tumours and died with leukæmia. In the control animals, tumours appeared on the eighth day after implantation and all animals died with leukæmia on the eighteenth–nineteenth day. Even when the treatment was delayed until the sixteenth day after tumour implantation, when the average size of tumour had reached 3·5 cm. and the white-cell count was about 70–90,000, compounds 1 and 3 still caused regression of all visible tumours; however, in this case, the tumours re-appeared after the treatment was discontinued, and the animals died.

Twenty-five patients with various advanced neoplastic diseases have been treated with compound 1. There was a remarkable absence of gastro-intestinal side-effects. The only side-reaction resembling those of known alkylating agents was depression of bone marrow. It is too early to evaluate the therapeutic results in these patients, although there are indications of anti-tumour effects.

Fluorescence of Tissue Culture Cells stained with Acridine Orange

ARMSTRONG[1] has shown that biological fluorochrome acridine orange under controlled conditions of *p*H differentiates in fixed tissues betwen deoxyribo- and ribo-nucleic acids, the former showing green fluorescence and the latter red. Schummelfeder, Ebschner and Krogh[2], who examined the nature of this specificity, have shown that acid or heat treatment of fixed tissue, prior to its staining by acridine orange, changes the green-yellow fluorescence of the nuclear matter to a copper-red colour similar to that given by ribonucleic acid in the cytoplasm. From their observations the authors suggested that the green and red shades of fluorescence of acridine orange are associated with high and low molecular-weight forms of the nucleic acids. The deoxyribonucleic acid within the nucleus, however, is characterized by: (*a*) high degree of polymerization and (*b*) high level of orientation, which includes its double-stranded form and the structural organization within the chromosomes. The inquiry conducted by Schummelfeder *et al.* does not indicate the level of depolymerization necessary for the change in fluorescence. It does not also completely eliminate the significance of orientation in the specificity of greenish fluorescence usually shown by chromatin matter within the nucleus stained by acridine orange.

We have made observations on the fluorescence given by some tissue-culture cells stained by acridine orange prior to, and after, their exposure to different dosages of X-rays. Intestine, HeLa, HeLL and conjunctiva cells were grown in basal Eagle's medium on slips in flat test-tubes. After 24 hr. incubation, the slips were transferred to standard veronal buffer (*p*H 7·3) and irradiated with X-rays (International G.E.C., 200 kV., 100 m.amp.; 160 r./min.) up to a maximum dose of 4,000 r. The cells were fixed immediately in 3 per cent formalin, then transferred to a buffer medium of the desired *p*H, and later stained with acridine orange solution in the same buffer at *p*H 3–6 and concentration 0·05 per cent. The non-irradiated cells were given the same treatment as irradiated ones. The fluorescence of the stained material was observed with blue-violet excitation by using the mercury arc lamp with Reichert blue filter No. 8027 at the source and minus blue filter No. 8006 at the eyepiece.

In the non-irradiated cells all the nuclei showed green fluorescence with nucleoli yellow. The cytoplasm showed crimson red fluorescence. On X-ray irradiation the red fluorescence of the cytoplasm did not show much change except slight intensification. The green-yellow fluorescence of the nuclei also did not show much change until the irradiation dose exceeded 2,000 r. There was, however, a marked change from green towards red when the dose was increased above 2,200 r. and no nucleus with a green fluorescence was left over on the slip, when the dose was greater than 3,200 r. Thus the change of nuclear fluorescence did not appear to be a gradual process but was distinctly confined to a narrow dose-range between 2,000 r. and 3,000 r. These results indicate that in the mechanism that shifts the observed nuclear fluorescence within cells, some step or steps that respond to a cumulative or multihit action of ionizing radiations are involved.

The depolymerization of deoxyribonucleic acid by ionizing radiations has been studied in the solution state by Butler[3], Conway[4] and Daniel, Scholes and Weiss[5]. Their observations indicate that in the aqueous solutions the immediate action on depolymerization of deoxyribonucleic acid by X-rays is very feeble although more significant 'after-effects' are seen. No results concerning the dose effect relationship for the after-effects are yet available. Under the conditions of the present experiments, however, depolymerization studies in the solid state of deoxyribonucleic acid seem to be more important; for the deoxyribonucleic acid within the cells is considered to be localized within their chromosomal structures, which are often characterized by their gel state containing about 30 per cent solid matter[6].

Observations on the depolymerization of deoxyribonucleic acid in the solid state by ionizing radiations have been reported by Alexander and Stacey[6]. Their studies do not indicate a multi-hit mechanism for the breaks in the main chain of deoxyribonucleic acid. Besides, on the basis of their results, an estimate of the drop in the average molecular weight of deoxyribonucleic acid at 3,000 r. does not amount to even 1 per cent. We are therefore tempted to conclude that the green fluorescence of deoxyribonucleic acid stained by acridine orange is associated with some more labile character, such as its native state, not affected by formalin fixation, rather than simply its high polymer nature.

Beers, Hendley and Steiner[7] have recently shown the formation of two types of complexes between acridine orange and nucleic acids. Complex I involved the bases and inter-nucleotide phosphates of ribonucleic acid. Complex II, however, involves the terminal phosphates of both ribo- and deoxyribo-nucleic acid. They further state that the green fluorescence of nuclei is the result of the formation of complex II with deoxyribonucleic acid and the red fluorescence of ribonucleic acid is due to the formation of the mixture of complexes I and II involving greater take-up of the dye. The critical level of irradiation observed by us might be causing some intramolecular disorientation of deoxyribonucleic acid, involving inter-nucleotide bonds, so exposing additional sites for subsequent binding with acridine orange .

It may be noted that Puck, Marcus and Cieciura[8], in their experiments on clonal growth of mammalian cells by feeder layer technique, observed complete suppression of multiplication among the population of 2×10^5 HeLa cells with an X-ray exposure of 4,000 r. They also found that these irradiated feeder cells, though unable to multiply themselves into colonies, showed otherwise active metabolism.

We are indebted to Dr. J. A. Armstrong of the National Institute for Medical Research, London, for his helpful criticism. Thanks are also due to Mr. C. V. Bapat, Tissue Culture Department, Indian Cancer Research Centre, Bombay, for the provision of tissue culture cells, and to Mr. A. D. Rahalkar, Radiology Department, Tata Memorial Hospital, Bombay, for his help in irradiating the cells. One of us (U. N. J.) expresses his gratitude to the Council of Scientific and Industrial Research, India, for the award of a research fellowship which enabled him to carry out this work.

Phenolic Acids as Growth and Germination Inhibitors in Dry Fruits

The presence and chemical composition of substances in fleshy fruits which inhibit germination and growth have been studied by several workers[1-3]. On the other hand, the chemical nature of the inhibitors in dry pericarps is but little known[4,5]; thus their detailed examination seemed to be justified.

The water- and ether-soluble inhibiting substances in fruits of twenty-four species (for example, capsulas, legumes, siliquas) were examined with paper chromatography together with bio-assay, then chemically identified. The identification was made on the basis of R_F values, ultra-violet fluorescence, colour reactions and comparison with synthetic compounds.

According to the results inhibitors are present in all the fruits examined. The inhibiting substances are localized in two main areas in the chromatograms. In the inhibiting zone, between R_F 0·0 and 0·35, many benzoic- and cinnamic-acid derivatives of lesser activity were found, such as large-molecule tannic acids, protocatechuic-, caffeic-, chlorogenic-, ferulic-, *p*-coumaric- and *p*-oxy-benzoic acids, and an unknown phenol derivative. From the inhibiting zone between R_F 0·55 and 0·75, strongly active salicylic acid and, in some cases, two unknown cinnamic acid derivatives were demonstrated. It may be supposed that isomers of the above-enumerated substances are also present on the chromatograms.

It is remarkable that all inhibitors, chemically identified from dry fruits, are phenolic acids or their depsides and polydepsides. These substances occur in various combinations and quantitative proportions in the different fruits, but are not specific. Comparing the inhibitors in dry fruits with those demonstrated from fleshy ones, a considerable conformity can be seen. This fact supports our earlier assumption that the occurrence of phenolic acids as inhibiting substances are common in higher plants.

The greater part of the inhibitors is washed out of the fruits which remain on the trees until the spring. The rate of the leaching depends very much on the structure of the pericarp and the chemical nature of the inhibitors. The results prove that storage in dry conditions has no effect on the quantity and quality of inhibitors in the fruits.

Details of this work will be published elsewhere.

Dose–Response Relationship in Radiation Leukæmia : the Marking Probit

Linearity (or non-linearity) of the leukæmogenic potency of radiations has been discussed extensively in the recent literature[1,2]. Experimental results are usually presented by plotting incidence in percentages versus dose on an arithmetical scale. A regression curve is then fitted for assessing a correlation between these variables. The form of a dose–response curve is apparently attracting more attention than the nature of the variables involved.

In any sample of susceptible individuals, some develop leukæmia as a response to irradiation at a given dose, others do not. The development of leukæmia is clearly an all-or-nothing effect, that is, a quantal response. This implies a distribution of susceptibilities within the sample. Susceptibility stands for our ignorance of all the factors upon which the development of leukæmia is dependent. From theoretical statistics, however, we know that quantal effects exhibit a sigmoid dose – response curve. Adequate statistical treatment therefore requires probit analysis. Probit regression curves fit experimental results on radiation leukæmias in *C 57 BL* mice[3].

The second variable is the dose. It may be satisfactorily defined by four parameters: magnitude, rate, fractionation and duration. Incidence of leukæmia has been shown to vary with these dose factors[4]. For probit transformation the distribution of susceptibilities must be approximately normal, or normalized by metametric transformation of dose (dosage). For *C 57 BL* mice, normalization can be effected by expressing the susceptibilities in terms of the logarithm of the dose; but nothing has been published about an appropriate dosage for radiation leukæmias in humans. In any event, the assumption that incidence is independent of dose factors is most probably inaccurate; and incidence in percentages and dose on an arithmetical scale are irrelevant variables.

An alternative can be introduced by assuming a linear correlation and looking for variables that possibly fit it. This approach has led us to define the marking probit as a working hypothesis. It is assumed that both lethal and leukæmogenic effects of radiation are independent quantal responses distributed in a population of hæmatopoietic mother-cells present in any irradiated mouse. This independence is supported by experimental evidence[5]. Let PM be the probability of any mother-cell showing the leukæmogenic response (marking) and PL the probability of the lethal response (death). The probability PA of a leukæmia being initiated in any irradiated mouse is assumed to be equal to the proportion of marked surviving mother-cells. This proportion is an estimate of the combined probability $PM(1 - PL)$. Hence $PA = PM(1 - PL)$. The probability of acute radiation death in mice and rats is related to the degree of hæmatopoietic destruction as shown by leucocyte counts[6,7]. To a first approximation, PL may be therefore estimated from the acute mortality percentage. Furthermore, the probability of any mouse developing a leukæmia PC (observed incidence in the sample) is dependent upon PA and the chances of own survival $(1 - PL)$. Thus $PC = PA(1 - PL) = PM(1 - PL)^2$. Hence $PM = PC/(1 - PL)^2$.

Values for PM have been calculated from Kaplan's and my own results. From Figs. 1 and 2 it can be seen that PM may be normally distributed on dose or logarithm of the dose. It is therefore called the 'marking probit', as percentages may be expressed in terms of probits. Available data do not provide statistical control of the best fit. It is interesting to note, however, that marking probits are independent of dose factors. They are exclusively a function of total dose. It may be concluded that successive doses are additive for the initiation of the leukæmogenic process but not for the ultimate development of radiation leukæmia. The distribution of marking probits suggests that leukæmogenesis may require more than a single critical molecular event, although such an event may be the initiating agent.

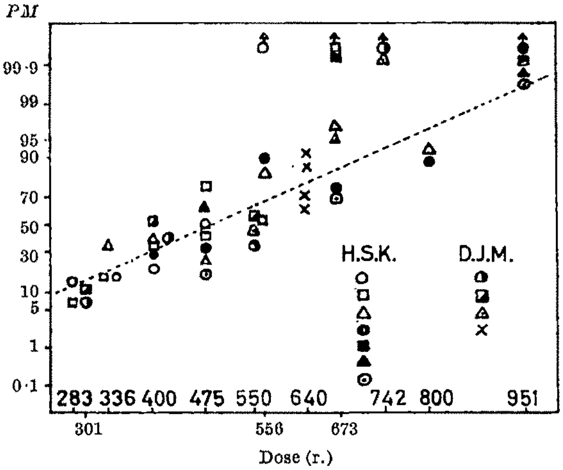

Fig. 1. Correlation between probability of a mother-cell showing the leukæmogenic response (PM) and total dose.
PM calculated from Kaplan's data: ○, single dose; □, 2 doses at one-day interval; △, 4 doses at one-day intervals; ●, 8 doses at one-day intervals; ◫, 4 doses at four-day intervals; ▲, 4 doses at eight-day intervals; ⊙, 4 doses at sixteen-day intervals.
PM calculated from my results: ◑, 2 doses at five-day intervals; ◪, 2 doses at five-day intervals + cysteamine; ◬, 2 doses at five-day intervals + cystamine; ×, 4 doses at seven-day intervals, with or without cystamine

Assimilation of Ammonia Nitrogen by Rumen Bacteria

Ammonia is always present in the rumen liquor of sheep[1] and the concentration varies with the kind of protein in the ration, but the addition of starch-rich foods such as maize meal or flaked maize to high-protein rations depresses the concentration[2–4].

The reason for this effect is not entirely clear; it is well known that the non-protein nitrogen of foodstuffs can, in part, substitute for protein in the ration, and this has led to the use of urea as a protein substitute in feeding cattle and sheep. There is evidence that nitrogen derived from urea can be assimilated by rumen bacteria when starch or maltose are present[5,6]. Assimilation of nitrogen-15 by mixed rumen organisms in the form of ammonia has been found[7], and variants of *Lactobacillus bifidus* isolated from the rumen are reported to assimilate ammonia nitrogen from the media[8].

The experiments summarized here were undertaken to examine the effects of different rations on the net changes of the ammonia content of rumen liquor and to obtain further information on the effects of starch on the possible assimilation of ammonia nitrogen.

The rumen liquor of sheep fitted with permanent rumen cannulæ and fed on various rations was withdrawn and incubated under carbon dioxide for 2–4 hr. at 37° C. Ammonium chloride was added to one of duplicate flasks to increase the initial concentration

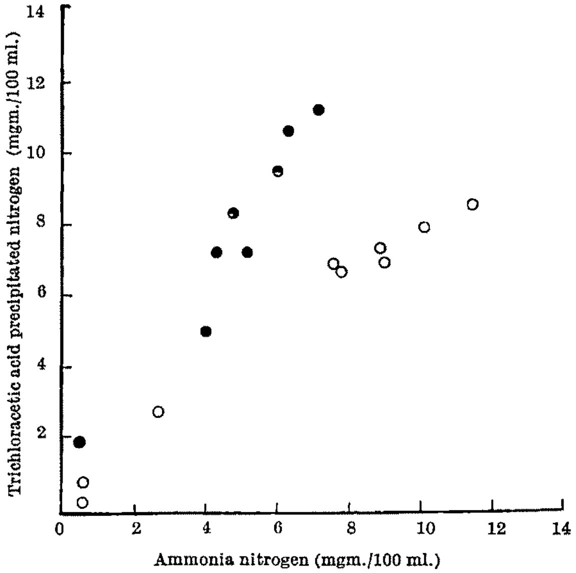

Fig. 1. The ammonia nitrogen lost from the media with peptone ● and without peptone ○ in relation to the nitrogen gained in the trichloracetic acid precipitate measured by direct determination using one culture incubated for periods of 12–96 hr.

of ammonia nitrogen by 40 mgm./100 ml. The total content of ammonia increased during incubation in the rumen liquor of sheep fed on grass or hay or sheep fed on hay with protein supplements. It decreased when the donor sheep were fed on hay with either fodder beet or a mixture of flaked maize and maize gluten meal. In the latter circumstances, the extent of the loss was variable and very occasionally did not occur. This was so if liquor was drawn before the first morning feed or if the sheep had a poor appetite, as occurred occasionally with the flaked maize ration. The loss of ammonia nitrogen from the rumen liquor of sheep fed the flaked maize ration was accompanied by an increase in the trichloracetic acid precipitate, and the use of ammonium chloride enriched with nitrogen-15 showed that ammonia nitrogen was concentrated in this precipitate. We are grateful to Dr. E. I. McDougall of this Institute for determining the concentration of nitrogen-15 in the various fractions before and after incubation.

A similar medium to that previously used[8] was devised containing starch and glucose in which ammonium chloride provided 87·1 per cent of the total nitrogen, *l*-cysteine 12·7 per cent and B vitamins 0·2 per cent. The whole was made up in a phosphate buffer, and trace elements were added. The media also contained acetate, a small quantity of citrate and 0·075 per cent agar. For solid media, the agar concentration was increased to 1·3 per cent. Liquid medium was gassed with oxygen-free carbon dioxide immediately after inoculation. Plates were incubated anaerobically under a gas phase of hydrogen containing 5 per cent carbon dioxide. Rumen liquor diluted in phosphate buffer was used for inoculating solid media and colonies were picked from plates and transferred to liquid media. Organisms isolated in this manner grew well. Isolates were obtained mainly from sheep fed on hay or hay and the flaked maize mixture with or without groundnut meal. *l*-Cysteine was essential for rapid growth. Replacement with thioglycollate allowed a less vigorous growth except when casein hydrolysate or methionine was added. *l*-Ascorbic acid or sulphide were ineffective even with methionine or casein hydrolysate. Growth did not occur in the presence of *l*-cysteine if ammonium chloride was substituted by sodium chloride. The majority of isolates were slender branching rods; but some coccal forms were also isolated. The general properties of all isolates were that starch and glucose were fermented with the formation of acetic and lactic acids and ammonia nitrogen was assimilated. The addition of peptone to the media caused more vigorous growth but ammonia nitrogen was still assimilated but to a less extent (Fig. 1).

The behaviour of cultures, however, was not always consistent, and after several subcultures some cultures produced ammonia when grown in the media with peptone, but after several further subcultures regained the property of assimilating ammonia nitrogen.

Additional examination of 28 isolates of the rod type showed that they all possessed the characters of lactobacilli; the sugars fermented were the same as those found for *Lactobacillus bifidus*[9]; the quantities of acetic and lactic acid formed were close to the ratio of 2 : 1; the lactic acid formed was found by Dr. T. M. Sutherland of this Institute to be the L(+) form. The morphological characters were also compatible with those described for *Lactobacillus bifidus*.

Table 1. THE MEAN LOGARITHM OF I + THE COUNT, WHEN THE COUNT IS GIVEN IN MILLIONS/ML., FOR SHEEP FED ON HAY (*H*), HAY AND GROUNDNUT MEAL (*H* + *G*), HAY WITH THE FLAKED MAIZE MIXTURE (*FM*) AND HAY WITH THE FLAKED MAIZE MIXTURE AND GROUNDNUT MEAL (*FM* + *G*)

	H	*H* + *G*	*FM*	*FM* + *G*	S.E. of difference (3 d.f.)
'Normal'	0·84	0·79	1·96	1·56	± 0·74
	0·81		1·76		± 0·52
'Peptone'	1·24	1·19	2·88	2·08	± 0·44
	1·21		2·48		± 0·31

Systematic plate counts of organisms in rumen liquor that would colonize on the media with or without peptone were made using eight sheep, pairs of which were maintained on one of the following rations: hay, hay with groundnut meal, hay with the flaked maize mixture and hay with the flaked maize mixture and groundnut meal. Four counts from each sheep were made over a period of four months and two sheep on different diets were sampled on each occasion. It was possible to eliminate differences between occasions when the results were analysed. Table 1 summarizes the results for the logarithm of I + the count with these occasional differences eliminated. It will be seen that using the medium with peptone ('Peptone') the rations containing the flaked maize mixture produced higher counts than the rations without this mixture ($P < 0{\cdot}05$). There is the same tendency with the counts made on the medium ('Normal') without peptone. The results with the 'Normal' media, however, are not significant, and this is probably due to one sheep in which no colony formation at all occurred on two occasions. The derived mean counts are given in Table 2. We are indebted to A. W. Boyne of this Institute for the statistical analysis of the results.

Table 2. THE MEAN COUNTS DERIVED FROM TABLE 1 IN MILLIONS/ML.

	H	*H* + *G*	*FM*	*FM* + *G*
'Normal'	11	10	151	60
'Peptone'	29	26	1,260	200

As colonies picked from 'peptone' plates had the property of assimilating ammonia nitrogen when grown in liquid medium, it appears as if the 'peptone' counts are more representative of the numerical importance of bacteria with this property than the more selective medium without peptone.

These experiments support the hypothesis that the depression in concentration of ammonia nitrogen that occurs when a starch-rich food is added to a high-protein ration may be due, in part, to an increase in the concentrations of bacteria that can assimilate ammonia nitrogen.

β-Globulin Polymorphism and Early Fœtal Mortality in Cattle

Six β-globulin types have been found in British breeds of cattle by starch-gel electrophoresis[1]. Mating data showed that the six types represent the individual homozygotes and heterozygotes of three β-globulin alleles, β^{A}, β^{D} and β^{E}. Five of these six types were seen independently by Hickman and Smithies[2], who postulated a similar genetic mechanism.

It has been found that the proportion of the two possible types of offspring from some reciprocal matings is apparently influenced by the maternal genotype. Thus, from certain matings involving only the alleles β^{A} and β^{D} equal numbers of offspring like or unlike the mother (with respect to β-globulin genotype) would be expected. However, a consistent excess of offspring like the mother was obtained from such matings in both Friesian and Ayrshire cattle (Table 1). Although several of the calves in the results were sired by the same bull the effect was not correlated with particular bulls. Because of the practice of early disposal of bull calves from dairy herds the data relate only to female calves. It is not yet known if the same phenomenon occurs with male offspring.

In similar matings involving the allele β^{E} a preponderance of like-mother offspring was found when this allele was in the fathers' genotype only (Table 2). From the corresponding reciprocal matings where the mothers' genotype included β^{E} a consistent lack of β^{E} offspring was found.

Table 1. Reciprocal Matings showing an Excess of Like-Mother Offspring in Two Breeds of Cattle

Mating	Offspring (female calves from cows mated with A.I. bulls)			
	Friesian		Ayrshire	
Dam × Sire	Like dam	Like sire	Like dam	Like sire
$\beta^{AA} \times \beta^{AD}$	19	11	0	0
$\beta^{AD} \times \beta^{AA}$	13	8	12	3
$\beta^{DD} \times \beta^{AD}$	17	9	3	1
$\beta^{AD} \times \beta^{DD}$	32	25	1	0
Totals	81	53	16	4
Significance	$\chi^2 = 5\cdot85$; $P = 0\cdot01$–$0\cdot02$		$\chi^2 = 7\cdot2$; $P = 0\cdot01$–$0\cdot001$	

Table 2. Reciprocal Matings involving the Allele β^{E} (Results from Several Breeds Pooled)

Mating	Offspring (female calves from cows mated with A.I. bulls)	
Dam × Sire	Without β^{E}	With β^{E}
	Like dam	Like sire
$\beta^{AA} \times \beta^{AE}$	6	5
$\beta^{DD} \times \beta^{DE}$	22	11
	Like sire	Like dam
$\beta^{AE} \times \beta^{AA}$	5	1
$\beta^{DE} \times \beta^{DD}$	8	2

It is unlikely that these effects can be explained by differential production of gametes, by selective fertilization, by differential mortality in calfhood or by unwitting selection by the dairy farmer. The only simple explanation appears to be that the chances of survival of the bovine embryo are affected by the β-globulin genotype of the mother. Thus embryos differing in genotype from the mother appear to be less compatible with the mother than those of like type, except where the maternal genotype includes β^{E}. Then there seems to be antagonism between β^{E} dam and β^{E} embryo causing a dearth of β^{E} offspring. In this connexion it is significant that β^{E} is the least frequent of the three alleles in each breed examined, and is in fact absent in Jersey, Guernsey and South Devon cattle. A gene at a disadvantage in a balanced polymorphic system must have some counterbalancing advantage or it would be eliminated by natural selection. Whatever the nature of this advantage for β^{E} it is presumably greater for northern breeds of British dairy cattle than for southern because the β^{E} frequency increases steadily northwards[1].

Because of the low frequency of β^{E} the losses due to the postulated antagonism between β^{E} dam and embryo would be numerically small. However, the losses due to the lack of unlike-mother offspring (Table 1) from matings involving β^{A} and β^{D} could be quite important. Assuming that one-third fewer unlike-mother offspring are produced, it can be calculated that when the frequencies of β^{A} and β^{D} are 0·5 and β^{E} nil, only 83 per cent of conceptions would result in viable offspring if there were no other causes of prenatal loss. This percentage will increase as the disproportion between the frequency of β^{A} and β^{D} increases.

Robinson has used data from several sources to compute the estimated extent of prenatal loss in the cow[3]. He concludes that 10 per cent of services to cows in œstrus do not result in fertilization, while the products of conception from 27 per cent die during the first three months of gestation. Data published by the Milk Marketing Board[4] indicate a consistent loss of about 12 per cent of fœtuses between the first and third months of pregnancy. The loss was unaffected by season for three years, although the overall conception-rate showed seasonal variation. This 12 per cent loss is in close agreement with the estimated average of 86–88 per cent viability due to mother – fœtus β-globulin incompatibility.

From these results one would expect a greater percentage of viable offspring from crosses between homozygous bulls and cows of the same genotype, β^{E} individuals excluded, than from other crosses. Data to check this are now being collected.

I am indebted to Drs. P. M. Sheppard and A. W. H. Braden for helpful suggestions and criticism.

Juvenile Hormone in Thymus, Human Placenta and other Mammalian Organs

The development of methods for extracting and assaying the juvenile hormone of insects[1] has encouraged a search for the same biological activity in animals other than insects. Schneiderman and Gilbert have reported the first progress in this direction. Ether extracts of various invertebrates, including Hydrozoa, Polychaeta, Oligochaeta, Holothuroidea, Balanoglossida and Decapoda, give positive tests for juvenile hormone when assayed on pupæ of the silkworm, *Antheraea polyphemus*[2]. Equally surprising is the demonstration of juvenile hormone activity in certain crude aqueous extracts of bovine adrenals[3].

These extraordinary findings suggested the need for a more complete census of the distribution of juvenile hormone activity among mammalian tissues and organs. Our present purpose is to report that most, and perhaps all, mammalian tissues contain demonstrable amounts of a substance the biological activity of which in the insect assay is indistinguishable from that of juvenile hormone.

Our initial studies were performed on 1-day-old rats which were anæsthetized and blended at room temperature in 3 : 1 diethyl ether–ethanol. After washing with water and evaporation of the solvent, a golden oil was obtained which gave positive tests for juvenile hormone.

Afterwards, we took advantage of the fact that desiccated pulverized preparations of individual bovine organs are commercially available from the H.M. Chemical Co., of Santa Monica, California, and the Nutritional Biochemicals Corporation of Cleveland, Ohio. 50-gm. samples of ten of these pulverata were blended and extracted at room temperature with diethyl ether, and the extracts washed several times with water. After evaporation of the solvent, the oily extracts were tested for juvenile hormone activity by a modified version of the 'wax test' described by Schneiderman and Gilbert[2,3]. In brief, a zone of cuticle, about 1 mm. square, was excised from the thoracic tergum of a previously chilled *A. polyphemus* pupa. The oily extract was applied topically to the exposed epidermis and the latter then capped and sealed with melted wax. If the extract contains juvenile hormone, a patch of pupal cuticle forms under the wax wound during the pupal–adult development[2,3].

Positive tests were obtained for extracts of the following pulverata: thymus, bone marrow, placenta, ovary, corpus luteum and adrenal cortex. Liver, testis, kidney and spleen gave negative tests.

The extracts were chromatographed on alumina columns by precisely the same techniques that fractionate juvenile hormone in extracts of insect material. The individual fractions were dissolved in a small volume of peanut oil and tested by injection into *A. polyphemus* pupæ. After this purification, all extracts, including those that were formerly negative, gave positive test for juvenile hormone activity. Among the ten pulverata, thymus gave extracts of highest activity and adrenal cortex of next highest.

These results were confirmed and extended in the preparation of very active fractions from fresh calf thymus and liver, beef tenderloin and fresh human placenta. Positive tests were also obtained from preparations of deep-frozen pituitaries of sheep.

In contrast to these uniformly positive findings on mammalian organs, we have failed to detect any trace of activity in wheat-germ oil, soy-bean oil or extracts of dried brewer's yeast.

Extracts of commercial lard gave negative tests. However, we can report that substantial activity is found in purified extracts of ordinary heavy cream and in products prepared from cream. In contrast to this, extracts of powdered skimmed milk are inactive.

In summary, the picture that takes shape reveals a very broad distribution in the mammalian body of a factor which is indistinguishable from the juvenile hormone of insects. In view of the extraordinary biological activity of this hormone on the growth, metamorphosis and aging of insects, it seems important to decide whether the juvenile hormone may play a part in mammalian physiology or whether its presence in higher forms is something of a biochemical curiosity.

This investigation was supported in part by a research grant from the Division of General Medical Sciences of the United States Public Health Service.

Recovery of Injected Progesterone and its Relation to the Onset of Human Labour

The conception that progesterone is the hormone responsible for the maintenance and therefore secondarily also for the onset of labour is based on several important findings: the indispensability of the corpus luteum for pregnancy in the rabbit[1]; the extraction of the effective substance from corpora lutea[2]; the role of progesterone in the implantation and early development of the fertilized ovum[3]; the excretion of progesterone as urinary pregnanediol and the relation between pregnanediol output and the prognosis of pregnancy[4]; finally, the elucidation of the mechanism of the endocrine control of the pregnant rabbit uterus[5–7].

In the rabbit the indispensability of progesterone for the maintenance of gestation is thus definitely proved. In the human, however, the role of progesterone in the maintenance and termination of pregnancy is much more obscure: it is not possible to prevent premature labour[8] and to prolong pregnancy[9] by means of progesterone administration; the increasing sensitivity of the myometrium to oxytocin at the end of gestation is not suppressed by progesterone injection[10]; the level of serum progesterone[11] and the excretion of pregnanediol[12] do not drop until after delivery.

It has, however, been reported[13] that in the first half of normal human pregnancy more than 20 per cent of administered progesterone is excreted as urinary pregnanediol, while less than 20 per cent is excreted in pregnancies which end in spontaneous abortion. A similar relation between myometrial reactivity and progesterone recovery was suggested by recent experiments made by me[9] on legal abortions by means of intra-amniotic formalin injections. Therefore, I supposed that such a relation may also exist in other cases of reactive myometrium, for example, prior to labour. No earlier investigation of progesterone recovery at the end of gestation has been reported.

Twenty-five normal and healthy women in different stages of pregnancy received 200–400 mgm. progesterone ('Proluton', Schering) as a single intramuscular injection. The urine was collected in 24-hr. samples, generally for 10 days, that is, 2–3 days before and 6–7 days after progesterone injection. Pregnanediol was determined according to Jensen's method[14]. By this method only pregnanediol (free and conjugated) is determined. The average pregnanediol excretion during 2–3 days before progesterone injection was taken as pre-injection blank. If labour occurred earlier than 3 days after progesterone injection, the period of observation was assumed to be too short; hence these cases were excluded.

In the first 36 weeks of pregnancy the recovery of injected progesterone was found to vary between 19 and 38 per cent with an average of 27 per cent (Table 1).

Table 1. Recovery of Progesterone as Urinary Pregnanediol before the Thirty-sixth Week and during the Two Last Weeks of Pregnancy

Length of gestation (weeks)	No. of cases	Progesterone recovery (per cent)	
		Range	Average
≤ 36	10	19–38	27
39–40	15	0–13	3

The large amount of endogenous pregnanediol excreted at the end of gestation and the great daily variations in the excretion cause some difficulties in calculating the recovery of progesterone during this period. In order to facilitate the calculation of recovery, large doses of progesterone were given (in most cases 400 mgm.). If, as in the first 36 weeks, 20–40 per cent of exogenous progesterone had been excreted (that is, 80–160 mgm. pregnanediol), this increase in pregnanediol output would necessarily have been observed. However, in the last two weeks of pregnancy no injected progesterone or only some few per cent were excreted (Table 1). It must therefore be concluded that a considerable decrease in recovery of injected progesterone occurs near term, apparently simultaneously with the increase in myometrial reactivity. This decrease in progesterone recovery may be due to: (1) a decrease in pregnanediol excretion and/or (2) a change in progesterone metabolism.

(1) A decrease in pregnanediol excretion would imply that the capacity of the kidneys to excrete pregnanediol is limited and that at term the upper limit is reached even before progesterone injection. If so, the excess of pregnanediol, produced by progesterone administration, must be excreted by some other route (the fæces ?). It is, however, difficult to understand why the upper limit should always be reached at the end of gestation, while it is never reached earlier in normal pregnancy, in both cases quite irrespective of the pre-injection level of urinary pregnanediol.

(2) A change in progesterone metabolism would mean that progesterone is transformed to metabolites other than pregnanediol. If so, the metabolic change may imply that neither endogenous nor exogenous progesterone ever reaches the myometrium as an effective substance. In this way the 'progesterone block'[5] is withdrawn as effectively as if the progesterone production had ceased. The difference between the rabbit and the human pregnancy, in respect of the endocrine control of the pregnant uterus, seems to be that in the rabbit only the amount of progesterone is of crucial importance, while in the human not only the amount but also the metabolism of progesterone are vital.

The relation between recovery of progesterone and myometrial reactivity, the nature of the decrease in recovery and the problem of other sources of urinary pregnanediol are now undergoing further investigation in our clinic.

Discrepancy between the Distributions of Iodine in Human Serum when estimated by Iodine-131 and Iodine-127

IN spite of indications to the contrary[1], it is generally assumed that only traces of iodotyrosines are normally present in circulating blood of human beings and animals[1,2]. This assumption is based on the distribution of the labelled iodoamino-acids observed after administration of iodine-131. Roche and Michel[1] state: "Thyroid hormone must be considered as being a mixture of L-thyroxine and L-3,5,3′-triiodothyronine and containing at least 90 per cent of the total plasma iodide". Previous work with stable iodine, however, suggests otherwise[3].

Recently, it has become feasible to determine the distributions of both the labelled[4] and the stable[5] serum iodine on the same chromatogram. Initial observations suggested a marked discrepancy between the distributions obtained by the two methods, as well as an unsuspectedly long equilibration period for iodine-131. These findings made in euthyroid individuals have been extended in a larger series, with essentially the same result.

Table 1. Distribution of Iodine-131 in the Non-protein Fraction of Human Serum

Patients*	Days after iodine-131	Percentage iodine-131 in DIT	MIT	I^-	T_4	T_3
Ha.	1	<1	<1	96	4	1

DIT, Diiodotyrosine; MIT, monoiodotyrosine; T_4, thyroxine; T_3, triiodothyroxine.

Blood for iodine-127 chromatography was secured from seven healthy medical students and older volunteers. Blood was also drawn for iodine-131 and iodine-127 chromatography from two euthyroid patients, nearly recovered from a coronary occlusion, following administration of 150 and 200 μc. of iodine-131 respectively and from two individuals following the administration of 125 μc. of iodine-131.

The results are presented in Tables 1 and 2. As expected, the greatest part of the radioactivity was present in the serum as iodide 24–48 hr. after labelling. After this, the activity appeared mainly in the thyronine fraction, although a sizeable proportion was present as iodide in all specimens studied. Very little iodine-131 was found in the tyrosine fraction, even 10 days after labelling.

In contrast, the iodine-127 measurements show that approximately half the circulating iodine was in the form of diiodotyrosine and monoiodotyrosine, half as thyronines, but virtually no iodide. The identity of the monoiodotyrosine and diiodotyrosine has been confirmed by one- and two-dimensional co-chromatography in the presence of the radioactive compounds, and also by the ceric sulphate – methylene blue reaction[5] with and without added standards.

The distribution of the serum-iodinated compounds estimated from iodine-131 labelling conforms well with the reports in the literature[2]. It is demonstrated in the present study, however, that equilibrium is not necessarily attained by 72 hr., as has been generally believed[6]. Thus it is clear that the time after labelling with iodine-131 is an important factor in the result, which must be considered in any evaluation or comparison of chromatographic data based upon radioactivity. Conclusions from much of the work in the literature may need reappraisal on this account.

The finding in this study that about one-half of the iodinated compounds in human serum is present as iodotyrosines when stable iodine content is measured is thus most surprising. Since the determinations of both iodine-127 and iodine-131 were made on the same chromatogram, and since the behaviour of both labelled and stable standards processed in the same way matched the compounds in serum, on one- and two-dimensional chromatograms, it is unlikely that the findings are due to artefacts[3].

A reasonable explanation for the discrepancy may be found in the fact that varying dilutions of the isotope must take place within the thyroid. There is approximately ten times as much iodine in the iodotyrosines as in the iodothyronines[5]. If each group of compounds were to be secreted into the blood on a 1 : 1 basis, the specific activity in the iodotyrosines would be one-tenth that of the iodothyronines. With the usual labelling doses of iodine-131 currently employed, this low level of activity would be regarded as not significant.

The effect upon thyroid function of a coronary occlusion in the two patients followed serially several weeks before the study with iodine-131 might account for the slow rate of incorporation of the isotope into the thyronine fraction. However, the iodine-131 values in the specimens obtained at 72 hr. in two healthy volunteers and serially in a euthyroid healthy patient not presented here with non-toxic diffuse goitre and the conformity between the iodine-127 values of the patients and those of the healthy subjects, suggest that the thyroids were normally active and that slow labelling is a normal event.

Since chromatography with iodine-131 does not reveal the true distribution of the stable iodine, it seems possible that determination of both radioactive and stable iodine distributions may be necessary if greater insight is to be obtained into the disturbed mechanisms underlying certain unexplained disorders of the thyroid such as sporadic non-toxic goitre.

Following this work, Dr. James Wynn, Veterans Administration Hospital, Durham, N.C., has also found discrepancies between the iodine-127 and -131 results using quite different methods for separating the iodocompounds.

We are indebted to Mr. Richard H. Mandl for his help with these experiments.

BIOLOGY

Functional Changes in the Vacuole-containing Bodies of the Gastric Parietal Cell

THE cytoplasmic inclusion known as the vacuole-containing body[1] was first found by Palade[2] in a study of the fine structure of the neurone and afterwards in tracheal, intestinal and renal tubular epithelia.

It consists of a cytoplasmic vacuole—0·2–1μ in diameter—bounded by a single membrane 60 A. thick, containing small circular vacuoles, 500 A. in diameter. No morphological changes have been hitherto described in vacuole-containing bodies and their function and nature are obscure.

Similar vacuole-containing bodies are found in the gastric parietal cells of the fasting mouse[3], where one or two are found in each section. They are smaller than the mitochondria, and consist of a vacuole—0·2–0·4μ in diameter—bounded by a single membrane, which contains a few small 500-A. vacuoles (Fig. 1*a*).

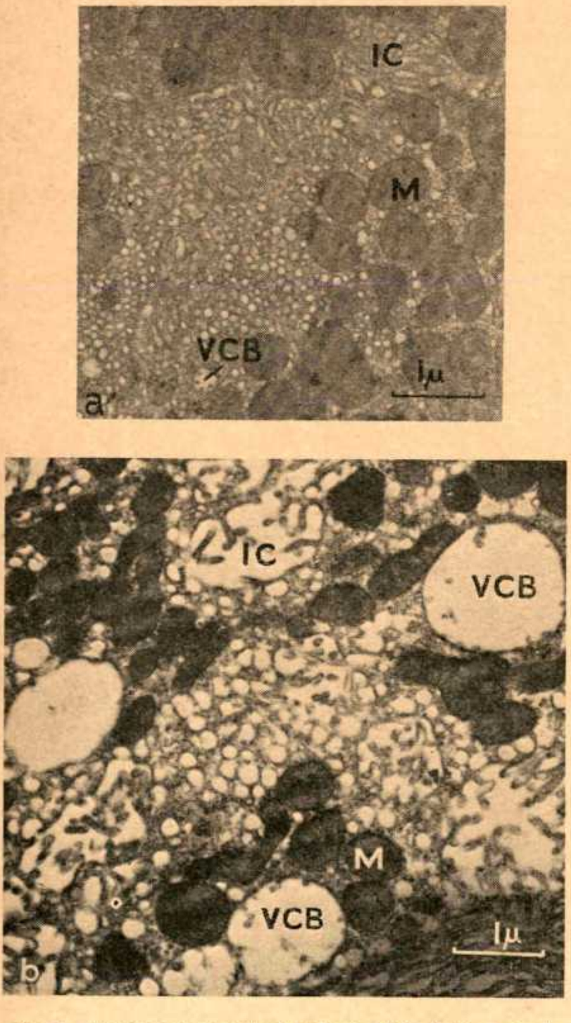

Fig. 1. Above: micrograph of parietal cell in fasting animal. A single small vacuole-containing body (*VCB*) is present. *IC*, intracellular canaliculus; *M*, mitochondria. (× 12,000). Below: micrograph of an actively secreting parietal cell. Several large vacuole-containing bodies (*VCB*) are visible. *IC*, intracellular canaliculus; *M*, mitochondria. (× 12,000)

Following repeated injections of pilocarpine nitrate, certain changes occur within the parietal cell. The vacuole-containing bodies become more numerous—about 5–7 occur in each section—and are much larger, namely, 0·5–3μ diameter. The small contained vacuoles are unchanged in size, although their total number has increased (Fig. 1*b*).

Thus in the gastric parietal cell the vacuole-containing bodies undergo marked morphological changes according to the secretory state of the cell. Phase-contrast microscopy of 2-μ sections confirms that these vacuoles are visible in the active parietal cell, and thus it should be possible, with routine histochemical methods, to elucidate the nature of this structure.

Induction of Lung Tumours by Radioactive Particles

INHALATION provides one of the most accessible routes for the entry of radioactive materials into the body. To evaluate the health hazards of airborne radioactive particles, it is important to know the biological effects of their deposition in the respiratory tract. When relatively insoluble particles are involved, pulmonary tissues may receive a large radiation dose because of a low rate of clearance from the lungs. The occurrence of squamous cell carcinomas as a result of the intratracheal injection of $^{239}PuO_2$ was initially reported from this laboratory[1]. Recently, malignant tumours were described in rat lungs after intratracheal administration of $Ba^{35}SO_4$ and $^{144}CeF_3$ (ref. 2), polonium-210 (ref. 3), and after implantation of strontium-90 glass beads and cylinders plated[4] with ruthenium-106. This communication concerns the occurrence of malignant lung tumours in mice after intratracheal administration of $^{106}RuO_2$ as well as $^{239}PuO_2$.

Suspensions of $^{239}PuO_2$ and of $^{106}RuO_2$ particles suspended in either 0·1 per cent 'Tween-80' (Atlas Powder Co.) or 0·1 per cent 'Pluronics' (Wyandotte Chemical Corporation) were administered intratracheally to two-month-old female BAF_1 mice. Barium sulphate particles were also given to a group of mice as an example of a known innocuous particle[5,6]. Stable ruthenium dioxide was administered to an additional group of control animals. The relative insolubility of $^{106}RuO_2$ and $^{239}PuO_2$ was shown in other experiments[7,8]. Approximately 20 per cent of the original dose was present in lungs after 100 days and 5 per cent after 400 days. The mice were killed either 100 or 500 days after treatment and examined grossly and histologically for pathological changes.

Grossly, two types of lesions were distinguished: pulmonary papillary cystadenomas and pneumonitis. The tumours were pearly white and frequently located near the pleura. These tumours were easily identified unless obscured by pneumonitis. The pneumonitis was bacteriologically sterile, and the affected lungs were pale with focal necrosis.

Table 1. INCIDENCE OF PATHOLOGICAL FINDINGS IN LUNGS AFTER INTRATRACHEAL INJECTION OF PARTICULATES

Material injected	100 days			350 to 500 days				
	No. of mice	Percentage with papillary cystadenomas	Percentage mice with pneumonitis	No. of mice	Percentage with papillary cystadenomas	Days after administration	No. and type of malignant tumour	Calculated dose (rad)
None	50	14	0·0	28	78	403–470	0·0	—
0·1 ml. distilled water	25	16	0·0	15	66	430–479	0·0	—
0·1 mgm. 'Tween-80'	25	8	0·0	18	39	386–513	0·0	—
5 μgm. $BaSO_4$	55	16	5·0	4	100	405	0·0	—
0·01 mgm. 'cold' RuO_2	46	28	7·0	21	9	335–500	0·0	—
3 μc. $^{106}RuO_2$	41	56	42·0	23	82	350	1 undifferentiated	9,000
1·93 μc. $^{106}RuO_2$	—	—	—	11	90	369–422	1 alveolar cell	4,000
0·15 μc. $^{106}RuO_2$	—	—	—	10	—	340	1 lymphosarcoma	300
0·06 μc. $^{239}PuO_2$	25	20	72·0	17	51	400	2 squamous cell carcinoma	2,300
0·003 μc. $^{239}PuO_2$	30	30	—	21	30	500	1 fibrosarcoma	115

The results of gross and microscopic examinations are given in Table 1. No demonstrable increase in the incidence of papillary cystadenomas was observed in animals treated with radioactive particles. At 100 days pneumonitis was not seen in controls but occurred only after administration of particles. Pneumonitis was observed in about 5 per cent of animals administered barium sulphate or ruthenium dioxide. After administration of ruthenium-106 and plutonium-239 pneumonitis was observed in 42 and 72 per cent respectively of the animals.

A marked increase in histological effects was observed at 350–500 days relative to the earlier period in mice given radioactive particles. Sections of lungs from mice killed 100 days after administration of 0·06 μc. $^{239}PuO_2$ showed foci of proliferation of bronchiolar epithelium and squamous metaplasia. These lesions were within foci of fibrosis which surrounded deposits of radioactive particles. After 400 days many grossly affected lobes appeared atelectatic and fibrotic. Such lesions showed a progression of the fibrosis and epithelial hyperplasia with associated tumour development as described below. The lungs of mice given ruthenium-106 grossly appeared hyperæmic with discrete areas of fibrosis. Microscopically, epithelial proliferation was not apparent, but areas of necrosis and fibrosis were observed. The latter contained cells with large, bizarre, hyperchromatic nuclei. Several malignant tumours occurred in mice given radioactive particles. These were found after administration of $^{106}RuO_2$ and included an undifferentiated anaplastic tumour, an alveolar cell tumour, and a lymphosarcoma. Two squamous cell carcinomas and a mediastinal fibrosarcoma were observed in mice given $^{239}PuO_2$.

Estimates of the total dose to lung tissue for the mice showing malignant tumours are included in Table 1. The dose values were derived by assuming uniform distribution of the material in the lung and exponential loss with an effective half-life of about 30 days for $^{106}RuO_2$ and $^{239}PuO_2$ administered intratracheally. Since non-uniform distribution of the particles was evident from autoradiograms, microscopic volumes of tissue received doses larger than those estimated. The lymphosarcoma in the lung and the mediastinal fibrosarcoma had the lowest estimated radiation exposure of 115 and 300 rad. The genesis of these tumours had a less-certain relationship to the deposition of radioactive particles. The lungs involved showed no evidence of radiation tissue effects at autopsy, and the cell types may be considered atypical for radiation-induced tumours in this location. The other doses exceeded 2,000 rad and are in the range of estimated radiation doses which caused malignant pulmonary tumours in experiments summarized in the report of the Sub-Committee on Inhalation Hazards of the National Research Council[9].

Sexual Maturity in *Drosophila*

D. J. MERRELL[1] says in regard to the fertility of matings of *Drosophila* when employing males less than 24 hr. old and males aged for seven days: "The unaged flies were left together in the creamers for periods ranging from 18 to 72 hours; the aged flies were separated after 2 to 7 hours, the variation in time being due to differences in the length of time needed for fertilization to occur".

According to Bodenstein[2], formation of mature spermatozoa is initiated in the pupal stage around three days before emergence of the pupæ. But it is not until about 7 hr. after eclosion that the first motile sperms appear[3]. Thus a successful mating before this time is unlikely. However, observations of mating behaviour of young males indicate that they very infrequently mate before they are 12 hr. old.

It seems that young males, that is, 0–1 day old are more reluctant to mate than older males, that is, 3–4 days old. Thus, a personal communication from Lüning informs me that in tests he has made very small progenies are obtained from young males when the mating period is 60 min., compared with large progenies from older males. When the mating period is extended to 2–3 hr. even the young males have large progenies. Another observation by Lüning is that in the group with young males the first male copulated 30 min. after they were brought together with the females, while in the group with older males the first males had started mating already after 3 min.

That there are also strain differences in regard to rate of sexual maturity is indicated by the experiment described below.

Males 0–3 hr. old, but with fully stretched wings, were mated individually to single virgin hybrid females. When the males were 24 hr. old, they were given a new set of virgin females for another 24 hr. Then the males were discarded. The females were permitted to lay eggs for a 3-day period after the mating period. Later all vials were observed for hatched eggs. The experiment was carried out at a temperature of 25° C. Table 1 gives the results obtained for the two wild-type strains, Iso-Amherst and Oslo. These results indicate that there is a significant difference between these stocks regarding the frequency of successful cultures obtained from males 0–24 hr. old, but no significant difference when the males are 24–48 hr. old.

Table 1

Strains	First brood			Second brood		
	Total No. of cultures	No. of successful cultures	Successful cultures (percent)	Total No. of cultures	No. of successful cultures	Successful cultures (percent)
Iso-Amherst	117	42	35·9	112	98	87·5
Oslo	113	67	59·3	108	89	82·4

This would indicate that males from the Oslo strain reach sexual maturity at an earlier age than males from the Iso-Amherst strain.

For both strains there is a significant difference between successful cultures on the first and second day. This holds true for several wild-type strains tested.

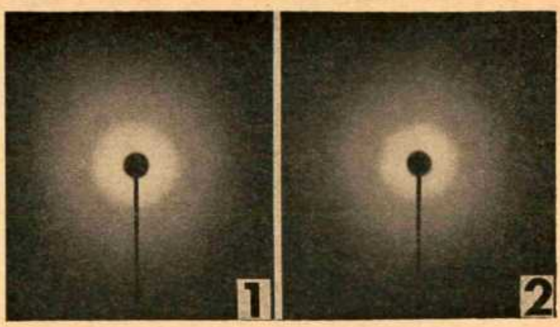
X-Ray Diffraction Patterns from the Egg Membrane of the Egg of the Brook Trout

STIMULATED by the findings of Young and Inman[1] and Brown[2] that the capsule of salmonid eggs can be classified as a pseudokeratin, we have recently made X-ray studies of the egg membrane of the brook trout, *Salvelinus fontinalis*. The membrane from the fresh unfertilized egg was washed with Ringer's solution to remove traces of egg contents and dried at room temperature. For analysis a Laue-type diffraction camera was used, with a flat film cassette 4·8 cm. from the specimen. The diagram obtained with copper K_{α} radiation, either vertical or parallel to the surface of the dry specimen, was a continuous halo with two main peaks at about 4·5 A. and 13 A. respectively (Fig. 1). As is also seen in Fig. 1, there is a sharp ring surrounding the whole halo. However, examination reveals that this ring coincides with the strongest line of sodium chloride, 2·81 A., and is wholly lost from membranes which have been washed with fresh water prior to desiccation. Consequently, it may be assumed that this ring pattern is not characteristic of the egg membrane, but is merely caused by adherent crystals of sodium chloride from the washing medium.



Figs. 1 and 2. X-ray diffraction diagrams of the egg membrane (vertical to the membrane surface). 1, Egg membrane of intact, unfertilized egg; 2, membrane taken from activated egg

As has been pointed out by various workers, salmonid eggs have a weak and fragile capsule until shed, but become much tougher, so-called water-hardened, at the time of fertilization or artificial activation[3–7]. As to the mechanism of such membrane hardening, Hayes[3] has suggested that it is a "special case of the reorganization of a protein molecule to form a keratin-like substance". It is of interest to see whether this idea is confirmed by changes in X-ray diagrams. Therefore, the egg membrane taken from eggs undergoing activation in fresh water was subjected to X-ray analysis. Contrary to expectations, the diagram was of similar halo type, giving no evidence of keratin (Fig. 2); no significant difference was found between the two diagrams by the microphotometric examinations. The present X-ray studies thus afford no proof of the change in the molecular organization of the egg membrane supposed to occur at the time of laying.

We are grateful to Prof. K. Niwa, Hokkaido University, and to Dr. T. Katsufuji, for their valuable suggestions and criticisms during the course of the present work.

Micro-Electrode Penetration of Ascites Tumour Cells

EHRLICH ascites tumour cells from mice were suspended in Krebs phosphate Ringer in agar and maintained at 37° C. in a small chamber. Ling–Gerard micro-pipettes were filled with 3 *M* potassium chloride. They had a tip resistance of 30–50 megohms, and were checked for tip potentials by Adrian's method[1]. Any showing tip potentials greater than 2 mV. were discarded. Penetrations were observed microscopically under a magnification of 600.

The input valve ('Hivac' *XE*2) and micro-pipette holder were carefully insulated from earth, the measured input resistance being greater than 10^{11} ohms. The grid current was less than 10^{-13} amp., the valve being biased above contact potential so that with the grid open, or the tip of the micro-pipette deliberately blocked by pushing it into the 'Vaseline' lining the bath, a negative potential resulted.

In general, a difference of potential of 5–10 mV., positive inside, appeared when the microtip just penetrated the cell wall. This difference of potential was stable and could be obtained repeatedly on successive impalements of the same cell. The microtip could be moved about inside the cell for a small distance without changing this difference of potential.

On pushing the microtip farther into the middle of the cell the difference of potential changed abruptly to a value of 20–40 mV., negative inside. This difference of potential remained constant for about 10 sec. and then declined slowly; small movements of the tip caused no further change. If the tip was withdrawn after one or two seconds, the sequence just described could be obtained several times in one cell.

Under favourable conditions the following sequence of events is observed. On bringing the microtip up to the cell a slight dimpling of the outer wall is seen. As penetration occurs this dimpling disappears and the cell seems to seal itself around the tip, as usually occurs with other types of tissue. At this stage a difference of potential of 5–10 mV. appears abruptly. As the tip is moved farther into the cell, an invagination appears in the interior granular material. This suddenly disappears and at the same time the potential difference changes abruptly to 20–40 mV., negative inside. In some cells the negative difference of potential appeared immediately on penetration. In others only the positive difference of potential was obtained, but in most of these the negative difference of potential appeared on a second penetration in a slightly different direction.

It would seem that the initial positive difference of potential exists between the cytoplasm and the external medium and that the negative difference of potential occurs on penetration of some internal structure of the cell.

Electron micrographs[2] show that the ascites tumour cell, the diameter of which is about 20–30μ, contains a very large nucleus, which may occupy up to half the volume of the cell and is often situated eccentrically; and that as the cells deteriorate they may develop vacuoles almost as large. However, with cells that were obviously deteriorating, the negative difference of potential was elicited much less frequently (although the positive could usually be obtained). Thus it is probable that the structure penetrated was the cell nucleus.

The positive internal potential of the cytoplasmic membrane could be explained, on the basis of the Goldman equation, if one assumes a high permeability to sodium compared with potassium[3]. It has been shown[4] that these cells have an abnormally high permeability to sodium.

I wish to thank Prof. F. H. Shaw for his encouragement and helpful advice during the course of this work.

Differences between Self-Incompatibility and Self-Sterility

THE term 'self-sterile' is used for describing plants which fail to set self-seed when they are grown in isolation or when they are self-pollinated. Silow[1] reviewed the early usage of this term and proposed the term 'voluntarily self-sterile' to describe *Lotus* plants that fail to set seed when isolated from insects and 'artificially self-sterile' when they still fail to set self-seed following artificial self-pollination. He observed that several *Lotus* species in isolation set more self-seed following artificial self-pollination than the same plants without artificial self-pollination. This difference can be accounted for by the presence of a stigmatic membrane which prevents germination and growth of any pollen. This membrane is ruptured by artificial self-pollination or by insect pollination of the flower, after which pollen can germinate and grow. The presence of a stigmatic membrane was observed by Elliott[2] in *L. tenuis* and by Giles[3] in *L. corniculatus*. Giles[3] was unable to observe any difference in germination between self- and cross-pollen once the membrane ruptured. The presence of a similar membrane was observed by me[4] in several other *Lotus* species. This membrane can account for the observed voluntary self-sterility and for differences between voluntary and artificial self-sterility, but it does not account for artificial self-sterility.

Several mechanisms which can cause artificial self-sterility are known. One of these is genetic 'self-incompatibility', as was first described by East and Manglesdorf[5]. Another is 'somatoplastic sterility' which causes post-fertilization abortion, first described by Brink and Cooper[6]. Several other possible causes have been postulated. Mechanisms which involve post-fertilization abortion lead to destruction of individual ovules, whereas incompatibility saves the ovules for fertilization by any cross-pollen that may be present. Post-fertilization abortion may be suspected if all ovules do not form seeds following pollination by a mixture of cross- and self-pollen. However, variability in rate of ovule development within ovaries may be expressed in the same way, as discussed by me[4].

The terms 'self-incompatibility' and 'incompatibility' are used for describing certain genetic outbreeding mechanisms of a type first described by East and Manglesdorf[5]. Two main systems are found in angiosperms with homomorphic flowers. These systems are controlled by incompatibility alleles at one or two loci in which incompatibility is found between the alleles in the pollen grain and the flower pollinated (gametophytic) or between the alleles of the pollen parent and the flower pollinated (sporophytic). The actual systems found are listed by Pandey[7]. These systems act on the incompatible pollen by retarding or inhibiting growth of pollen tubes. If a mechanism is provided to ensure that cross- and self-pollen germinate on the stigma at the same time, retarded growth alone will provide an effective incompatibility mechanism. This is a function of the stigmatic membrane in *Lotus*.

From these definitions, it can be seen that a self-sterile plant species may possess a genetic self-incompatibility mechanism; but it does not follow that the self-incompatibility mechanism is the direct cause of self-sterility. Also, a voluntarily self-sterile species which possesses an effective self-incompatibility mechanism may be either artificially self-sterile, artificially self-fertile or intermediate between these two possible extremes.

Our work with *Lotus corniculatus* indicates the importance of recognizing that incompatibility and self-sterility may be separate phenomena with independent genetic mechanisms. The presence of an incompatibility mechanism is indicated by differential growth-rates of pollen tubes within the ovaries with self- and cross-pollinations, as reported by Giles[3]. Also, the good fits to hypothetical genetic ratios obtained by Dawson[8] would be unlikely if an incompatibility system were not present, as he did not practise emasculation. The presence of self-sterility is indicated by reduced pod and seed set from flowers that are isolated from insects or from flowers that are self-pollinated, which has been demonstrated repeatedly as reported by Silow[1]. Giles'[3] observation that self-pollen tubes reach the base of the ovary beyond the basal ovules, although more slowly than cross-pollen tubes, and his further observation that the relative growth-rate of cross- and self-pollen tubes are the same in relatively self-fertile and self-sterile plants, are an indication that self-incompatibility is not the cause of self-sterility in *Lotus corniculatus*. Giles[3] and I[4] observed evidence of post-fertilization abortion following selfing and I also noted that some aborting ovules exhibited characteristics of 'somatoplastic sterility'. This may account for the observed self-sterility. Therefore, self-incompatibility and self-sterility should be considered as separate phenomena in this species.

It follows that self-sterility and self-incompatibility in *L. corniculatus* may be controlled by separate genetic mechanisms. Observations were made on pod and seed set from various reciprocal test crosses, including 64 test backcrosses between progeny and each parent, 56 test backcrosses between backcross progeny and the recurrent and cross parents, 157 S_1 progeny and their parents and 30 S_1 siblings were test crossed in all combinations. Although there was considerable variability in seed and pod sets, it was not possible to fit these data to any one-locus gametophytic incompatibility hypothesis, even if allowance is made for possible tetrasomic inheritance. Pandey[7] pointed out that certain incompatibility systems are characteristic of families and that this system is the one characteristic of Leguminosae. With further analysis, it was not possible to fit the data obtained to any of the other incompatibility systems that were listed by Pandey[7]. The results on setting of seeds and pods can be fitted to a polygenic inheritance model, as would be expected if self-sterility is caused by loss of heterosis leading to somatoplastic sterility. It appears that the results obtained measure self-sterility and that no evidence on the genetics of self-incompatibility has been obtained. It is highly probable that independent genetic mechanisms control self-incompatibility and self-sterility in this species.

The concept that incompatibility that does not produce self-sterility may be effective in outbreeding was developed by Bateman[9]. In *Lotus corniculatus*, it should be possible to breed out self-sterility without weakening the self-incompatibility system. Then, if suitable inbred lines can be produced, it should be possible to produce hybrid seed commercially in isolated fields using insect pollinators. We would expect a high proportion of hybrid seed from every flower that is visited by an insect carrying a mixture of pollen. Bees could also be used for producing self-seed in other isolated fields since incompatibility does not cause self-sterility. Fields used for hybrid seed production could be seeded in alternate rows or with mixtures of self-seed. Since evidence of hybrid vigour in *L. corniculatus* has been obtained by Mr. N. C. Lawson at Macdonald College (unpublished work), this offers a promising approach to breeding this species. It would appear that a similar approach would be very promising in other legumes where it may be possible to separate self-incompatibility and self-sterility. For example, the breeding plan for *Medicago sativa* presented by Bolton[10] may be more practical if these considerations are applied in this instance.

These results will be published in detail elsewhere.

I wish to acknowledge the help given in discussion by Drs. H. A. Steppler, R. I. Brawn and W. F. Grant.

A Technique for the Sterile Culture of Roots

The experimental methods which have been employed for studies of metallic ion deficiency effects in plant and animal chromosomes have hitherto involved the entire organism[1,2], and consequently have been under conditions of only partial control. It seemed desirable to design a method by which control of cell nutrition could be more closely approached. The method was developed for use in investigations of the effects of metallic ion deficiencies or excesses on chromosome structure, but it is not limited to experiments of this type. The technique has a two-fold advantage. In addition to maintaining control of nutrition, it is possible to use clonal lines of tissue for cytological studies, since many lateral roots can be obtained from a single bean of *Vicia faba*, and these roots can be maintained in culture. Brown and Possingham[3] have used a root-culture technique for

investigations of the effect of iron in *Pisum*, but their method differs somewhat from that described here because of a difference in the handling of the organisms, and the purposes for which the roots were cultured were not entirely the same.

The medium used is a modification of that developed by Bonner and Addicott[4]. The trace elements in the medium follow those used by Brown and Possingham. Each component of the medium is made up as a concentrated stock solution (Table 1) which can be kept refrigerated or frozen, and is diluted into the final volume of medium each time fresh medium is prepared. The vitamin solution (Table 2) is prepared by filter-sterilization and kept frozen in small aliquots which are added to the medium after the latter has been autoclaved. The medium is placed in milk dilution bottles which can be fitted with a Cornwall syringe apparatus, and the bottles are sterilized at 20 lb. pressure at 121° F. for 20 min. Following sterilization, the medium can be stored under refrigeration until needed, at which time the sterile vitamin solution is added.

Seeds (*Vicia faba;* variety Seville Longpod: Carters Tested Seeds, Ltd., London) were chosen for their high percentage of germination and low frequency of spontaneous chromosomal aberrations. The seeds are sterilized by immersion for 30 min. in a saturated solution of calcium hypochlorite in which 3 gm. of wetting agent (for example, 'Dreft') per litre have been dissolved. Storage dishes containing pure silica sand (coarse grade, American graded sand) and distilled water are autoclaved. The beans are then partially embedded in the sand. 'Vermiculite' should be used in place of the sand if the beans are not to be grown deficient in metallic ions. The beans are allowed to grow at 20–25° C. for 7–10 days. The sand is kept very moist, but with little or no excess water. When lateral roots appear to be at least 2 cm. in length they are ready for excision and transfer to culture plates. The lateral roots can usually be seen along the bottom and sides of the storage dishes. *Allium cepa* seeds, variety Southport White Globe, Associated Seed Growers, New Haven, Conn., were also used. These are sterilized as described for *Vicia faba* and placed in sterile Petri plates on moist filter paper. The roots are ready for excision and transfer to culture plates after about 4–5 days, when they are 2–4 cm. in length.

A thin layer of 'Pyrex' glass wool is placed in a 5-cm. Petri dish and the plates are autoclaved. Filter paper or fine graded, pure silica sand can be used in place of the glass wool if deficiencies are not required. Sterile medium is dispensed into the Petri dishes by a Cornwall syringe in amounts of 2–2·5 ml./plate. The medium used at the beginning of culturing contains gibberellic acid. The amount of medium used is enough to wet the glass wool, sand, or filter paper thoroughly. Tips of the lateral roots of *Vicia faba* or primary roots of *Allium cepa* are cut to a length of 0·5–1·0 cm., and 4–5 tips are placed in each Petri dish. The roots are incubated at 20–25° C., and are kept moist, but not covered with the medium, as required during growth. Two days following root excision they are transferred to fresh medium in fresh dishes, the medium now lacking gibberellic acid. The latter is done since gibberellic acid tends to slow down growth following the initial elongation of the roots. The roots are kept moist as described, and transferred every 4–5 days to fresh medium. The standard Feulgen method is used for preparation of root tip smears.

This work was supported in part by the American Cancer Society, the National Science Foundation, and the U.S. Atomic Energy Commission.

Response of Rice to Small Differences in Length of Day

THE natural annual variation in length of day in Malaya is from 41 min. in the north (lat. 6° N.) to 8 min. in the south (Singapore; lat. 1° 20′ N.). The monthly differences in length of day in the principal rice-growing areas lie between 1 and 3 min. It has been recognized in reports of rice sowing date experiments in Ceylon[1,2] in Indonesia[3] and in Japan[4], that observed differences in time of emergence and maturation of the ear are possibly due to these small monthly differences in length of day. It has also been suggested that a decreasing length of day will advance flowering while an increasing length of day will delay flowering of rice[3,5].

Monthly sowings of a Malayan rice, Siam 29—an *indica* variety of rice (*Oryza sativa*, L.), were carried out at Malacca (lat. 2° 12′ N.) and Kota Bahru (lat. 6° 09′ N.) and the results (Table 1) show considerable variation in the times to emergence of the ear for each sowing date.

These results, which are typical of a number of experiments carried out in Malaya[5,6] show that plants sown in north Malaya flower earlier than those sown in the south for any given sowing date. The differ-

* Maximum and minimum lengths of day occur during the summer and winter solstice respectively.

ences are almost certainly not due to responses to temperature for there is very little change in temperature with latitude or season in Malaya[5]. Since the rice variety used in these experiments does not become sensitive to length of day until it is 4 weeks old, the lengths of day effective for inducing flowering must occur some 4 weeks after planting. The number of inductive short days which can be utilized by the plant in the north are more than in the south. They are also shorter. As short-day plants react to the dark period rather than to the light period, dark induction of flowering takes place in a shorter time in north than in south Malaya. Such sowing date experiments therefore indicate the photo-inductive effect of length of day to be cumulative, and suggest that the daily changes which occur with increasing length of day do not delay flowering and that the daily changes with decreasing length of day do not advance flowering.

To test this hypothesis, duplicate plants of Siam 29 were sown in pots in Kuala Lumpur (lat. 3° 08′ N.) and given continuous treatment with lengths of day differing by 5 or 10 min. The required lengths of day of 11 hr. 40 min.; 11 hr. 50 min.; 11 hr. 55 min.; 12 hr.; 12 hr. 5 min.; 12 hr. 10 min.; and 12 hr. 20 min. were obtained by covering each individual plant with an opaque cylindrical cover. All covers were removed manually as rapidly as possible each morning, and were replaced at the required intervals each evening. All covers could be removed within 4 min. Thus the day-length error in any one treatment was in the region of 15–20 sec.

The results, which record the mean time to 50 per cent ear emergence and to harvest for the duplicates, are shown in Fig. 1. In spite of the technical difficulties involved, the curves obtained are reasonably smooth. The results for 11 hr. 30 min. length of day has been taken from another experiment[6] carried out on the same variety. These results show that the response of Siam 29 is directly related to the length of day. The longer the total amount of darkness (that is, the shorter the day) received during the period of sensitivity the more rapidly does the ear emerge.

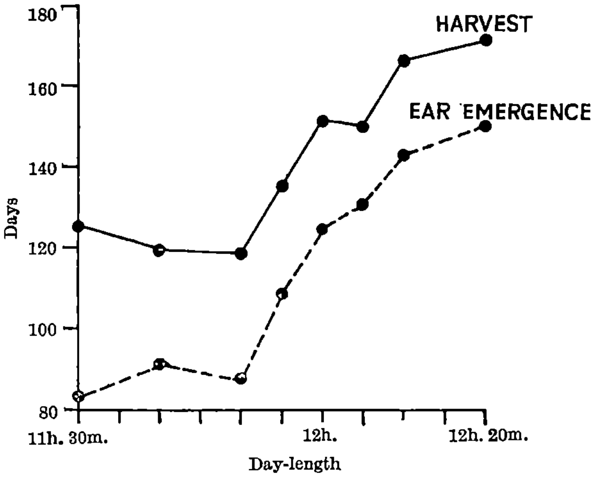

Fig. 1. Time to flowering and harvest in Siam 29

Chandraratna has produced curves of photosensitivity of a number of *indica* rice varieties, and these show that there are a minimum and a maximum length of day for effective flower stimulation. Rice is thus shown to be a short-day plant with a qualitative day-length response, which possesses no strongly defined critical day-length. Lang[8] has noted that plants with this type of behaviour cannot be fitted into the normal definitions of long- and short-day plants. Neither can their photosensitive behaviour be fully explained on the basis of the phasic and hormone theories of Gregory[9]; Hamner[10] and Lang[8]. The presence in such varieties of two limiting dark periods suggests that an internal mechanism of the diurnal type described by Bunning[11] provides a more satisfactory explanation for the behaviour of the plant to photoperiods of the order of 12 hr. If it is assumed that Siam 29 behaves in the same way as the varieties studied by Chandraratna[7] its response to very small differences is explainable, since the natural lengths of day found in Malaya and the lengths of day used in the experiment described here will fall in the steepest part of the photosensitivity curve characteristic of *indica* varieties of rice. Such lengths of day will also be of the same length as one of Bunning's[11] diurnal periods and will thus show the maximum inhibition of flowering, whereas plants receiving day-lengths less than 12 hr. will flower earlier because of the greater effectiveness of the light received during the middle of one of these periods.

It is hoped that further investigations of this phenomena will be made using a specially designed time-switch which can accurately control lengths of day to 1-min. intervals, and which is now available in this department.

I thank Mr. P. V. Thevan for technical assistance. This communication is published with the permission of the Director of Agriculture, Federation of Malaya.

A Method of growing Grass Plants with Separation of Seminal and Adventitious Roots

In the course of physiological investigations on grass roots it was necessary to grow plants of timothy (*Phleum pratense* L.) with their seminal and adventitious root systems separate from each other, so that different nutrients could be fed to each.

Although 'split root' techniques have been used in the past[1], no satisfactory method has been described. Timothy seedlings have a single, very thin seminal root easily killed by desiccation. Solutions can be supplied separately to seminal and adventitious roots, but tend to intermix as a result of capillarity or surface-tension effects. The following simple method of preventing this intermixture has been found to work well: plants have been grown to the flowering stage by this means.

Seeds are germinated on gauze ('Terylene' net, supported by a ring floating on dilute culture solution, has been found to be satisfactory). When the seminal root is 10–15 mm. long, but before adventitious roots appear, seedlings are transferred to containers constructed as shown, in vertical section, in Fig. 1. The pots are polystyrene containers now widely used for packing jam and other foods, and are obtainable in several colours or transparent and colourless. A glass tube is sealed by heat into a hole in the base of the inner pot, and passes through a larger hole in the base of the outer pot. Both pots contain dry 'Vermiculite', retained at the holes by glass wool. The polythene top of the inner pot has a short (3–4 cm.), fairly wide (4–5 mm.) glass tube sealed through it, and a small hole in the centre through which the seminal root of the seedling is threaded and afterwards sealed in, from the inside, with wax of low melting point (39° C.). This top, complete with seedling, is then fitted on the pot, and more 'Vermiculite' is added to the outer pot, covering the top of the inner one as deeply as possible without burying the seedling. The 'Vermiculite' is then soaked with water or culture solution, the glass tube in the lid of the inner pot being used for watering this pot. The lower tube prevents mixing of the drainage from the two pots: its end should be treated with wax or a silicone preparation to prevent liquid from creeping up it, or, alternatively, a length of flexible tubing may be attached to lead away the drainage.

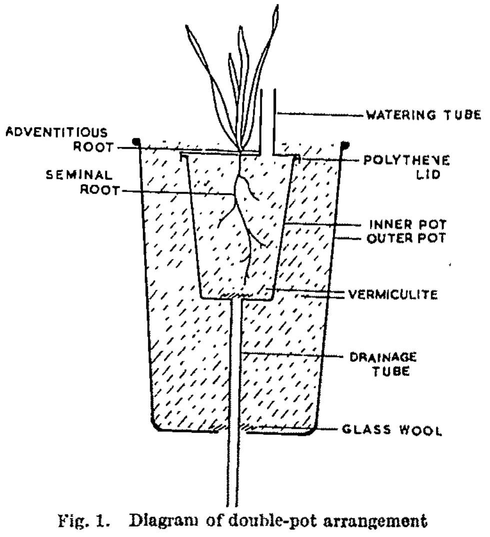

Fig. 1. Diagram of double-pot arrangement

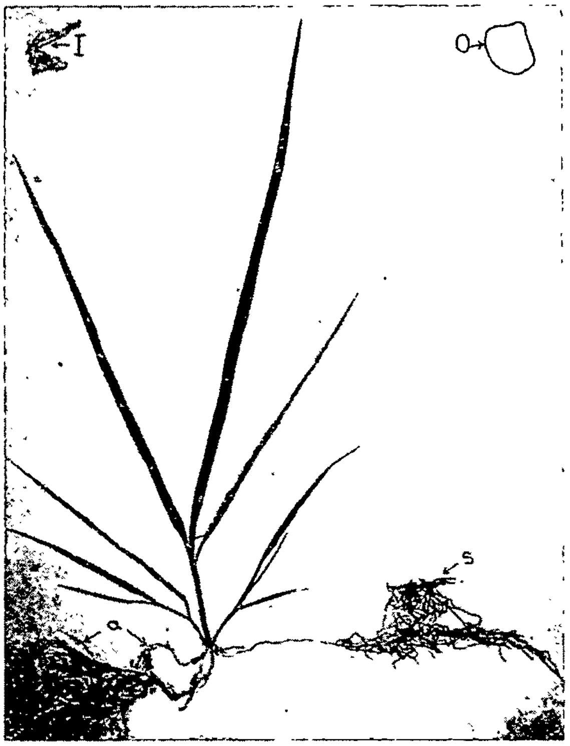

Fig. 2. Autoradiograph of a 5-week-old timothy plant. 5 μc. of sulphur-35 was given to the inner pot, and the plant was killed and exposed to X-ray film four days later. Film exposed for eight days. *s*, Seminal roots; *a*, adventitious roots; *I*, image given by 'Vermiculite' from the inner pot; *O*, position of 'Vermiculite' from outer pot

The pots used have capacities of 40–335 ml. However, a 335-ml. pot could conveniently be used as the inner one, with an ordinary plant pot as the outer; this would enable plants to be grown to a larger size before becoming 'pot-bound'.

A test was made to ensure that no transfer of solution took place between the two pots. 2 or 5 ml. of solution containing cæsium-137 were added to the inner or outer pots, respectively, of six containers in which there were growing seedlings. After a week, during which only enough culture solution was added each day to keep the 'Vermiculite' saturated, counts were made, with a scintillation counter and a ratemeter, of 'Vermiculite' from the untreated section of each container. The counts ranged from 2·9 to 3·3 per sec. (background count, 2·9) while a similar sample from a treated section gave a count of 60 per sec.

Experiments have since been carried out using sulphur-35 as a tracer. Autoradiographs were prepared of the 'Vermiculite' as well as of the plants. While in most cases the tracer has been found in both root systems, no matter to which it was directly supplied, 'Vermiculite' from the untreated pots has never given a positive autoradiograph, while that from treated pots has given a very clear image (Fig. 2). From this it is concluded that the sulphur-35 was translocated to the untreated root system through aerial parts of the plant, in which it was invariably found.

A. or mμ in Electron Microscopy?

It has become customary to express measurements made by the electron microscope in A. units. I have analysed this custom by examination of Vol. 12 of *Experimental Cell Research* (1957). Nine of the papers are concerned with electron microscopy. A. units are mentioned twice in theoretical considerations concerned with the minimum determinable thickness of a layer of osmium, and they are also used as ordinates in graphs. These uses of the units are here disregarded, because they are not actual measurements. (The use of A. units in reports of X-ray analysis is also disregarded.) With these exceptions, I find 129 measurements recorded in A. units in reports of work in electron microscopy. The last digit of 117 of these is 0; of ten, 5; of two (both in the same paper), 7.

It is clear that the last digit is not significant, and indeed this follows from theoretical considerations. It would be unreasonable to express all measurements made with the light microscope in 'decimicrons', but a better case could be made for this than for the use of the angstrom as the standard unit in electron microscopy. Actually, we have just the right denomination for electron microscopy in the millimicron (mμ). If we used this unit (as a few authors do), the last digit would be significant (though the tissues of organisms would necessarily have changed in dimensions before being measured).

It is a remarkable fact, not recognized by the inventors of the metric system, that the human mind jumps naturally in thousands. Thus we write 2,654,396, not 2,65,43,96 or 265,4396. Similarly, no denominations between millimetre and micron have been found necessary. The decimetre is seldom used, and the centimetre only gained popularity because it was arbitrarily chosen as the unit of length in the C.G.S. system. The really useful measurements of length are the kilometre, metre, millimetre, and micron; and the millimicron is the logical continuation of the series.

Reorganization of Microbiological Research in Britain

I write to report the views of the Council of the Institute of Biology on the leading article in *Nature* of January 3 which dealt with the reorganization of industrial microbiological research in Britain. The article was informative but did not, it is felt, bring out the fundamental points at issue.

The proposals to strengthen microbiology in the stations of the Department of Scientific and Industrial Research concerned with particular technologies and to support fundamental microbiological research within university departments are in themselves admirable. But the most urgent need in industrial microbiological research is for work that bridges the gap between fundamental university research and its applications in diverse technologies. Such work, basic research undertaken with the needs of technology in mind, is carried out in other fields by the National Physical and National Chemical Laboratories within the Department of Scientific and Industrial Research and elsewhere by the stations and university research units controlled by the Medical and Agricultural Research Councils. The Microbiology Group at Teddington was the only group in Britain doing work of this character in industrial microbiology.

The Research Council of the Department of Scientific and Industrial Research has now abandoned responsibility for microbiological research of this character, despite the acknowledged success of the Teddington unit. Its decisions make no provision for a research unit on general industrial microbiology within the Department of Scientific and Industrial Research. It should be clearly understood that university units similar to the Medical or Agricultural Research Council's research units at universities are *not* contemplated and that the research grants to be made available to university departments will be of the same character as existed before these decisions were made.

All parties that have made representations against these decisions, including the late Advisory Committee on Microbiology, the Institution of Professional Civil Servants and ourselves, have emphasized that the research needed in this field is of a long-term character; sometimes, as with the methane-producing bacteria, very long term. It requires a research centre—a government laboratory or university unit of some size—which will provide a career for mature scientists experienced in the needs of technology as well as pure microbiology. Short-term grants to support postgraduate students on isolated projects in university departments will be totally inadequate, though they would be a valuable supplement to work of such a research centre.

What, in fact, will happen if the decisions of the Research Council of the Department of Scientific and Industrial Research are carried out? The present research group at Teddington—small but important because of its collective strength—will disappear, and in our view little if any of its work will be continued elsewhere in Great Britain. The real value of its work has been appreciated by British industry and by microbiologists all over the world. The National Collection of Industrial Bacteria, a world-famous collection of high repute, will be removed to the Torry Research Station in Aberdeen, which houses a collection of marine bacteria excellent in itself but comparable neither in scope, reputation nor size. The Research Council will have antagonized the whole world of microbiology, both by its decisions and by its cavalier treatment of the late Advisory Committee on Microbiology; one may well ask how the Department of Scientific and Industrial Research can expect in the foreseeable future to recruit any reputable microbiologists. The Corrosion Group at Teddington will be strengthened; a few university departments will receive grants for isolated items of research, but these could be made available in any event.

It is hoped that something can be done to establish a small national laboratory for industrial microbiology to continue the work which has been carried out by the Microbiology Group and to initiate new investigations likely to have significance for industrial processes. Is there not a case for an expert committee, nominated perhaps by the Royal Society, to advise the Research Council on this matter?

D. J. B. COPP
(General Secretary)

Institute of Biology,

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, February 9

University College, Department of Biochemistry (in the Physiology Theatre, Gower Street, London, W.C.1), at 5 p.m.—Prof. A. Haddow, F.R.S.: "The Chemistry and Biology of Cancer".* (Further lectures on February 16 and 23.)

British Society for the Philosophy of Science (previously Philosophy of Science Group) (in the Joint Staff Common Room, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. P. G. 'Espinasse: "The Concept of the Gene".

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "Dissemination and Assimilation of Technical Literature" opened by Mr. J. K. Webb.

University of London (at King's College, Strand, London, W.C.2), at 5.30 p.m.—Dr. P. Ledoux (Université de Liège): "The Present State of the Stellar Stability Problem".*

Royal Aeronautical Society (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 6 p.m.—Mr. E. G. C. Burt: "Theoretical Studies of Guided Missile Control Systems".

Tuesday, February 10

University College (in the Anatomy Theatre, Gower Street, London, W.C.1), at 1.15 p.m.—Mr. F. Parkinson: "Social Problems of Underdeveloped Countries".

Royal Society of Arts, Commonwealth Section (at John Adam Street, Adelphi, London, W.C.2), at 5.15 p.m.—Dr. T. F. West: "The History of the African Pyrethrum Industry".

University of London (at King's College, Strand, London, W.C.2), at 5.30 p.m.—Dr. P. Ledoux (Université de Liège): "The Secular Stability of Stars and Stellar Evolution".*

Society of Chemical Industry, Chemical Engineering Group (at 14 Belgrave Square, London, S.W.1), at 6 p.m.—Mr. W. D. Jamrack, Mr. R. A. Wells and Dr. J. H. Buddery: "The Extraction of Thorium".

Royal Institute of Chemistry, London Section (joint meeting with the Sir John Cass College Chemical Society, at the Sir John Cass College, Jewry Street, London, E.C.3), at 6.30 p.m.—Dr. E. Lester Smith, F.R.S.: "Vitamin B_{12}—Recent Advances".

Wednesday, February 11

Physical Society, Low Temperature Group (at the Royal School of Mines, London, S.W.7), at 4 p.m.—Dr. T. J. Webber: "Some Problems in the Handling and Distribution of Liquefied Gases".

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. J. E. Prentice: "The Lower Culm Measures of the District South-West of Barnstaple, North Devon".

University College (in the Anatomy Theatre, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. H. Behnke (University of Münster): "Modern Theory of Complex Functions of Several Variables. 1: The Notion of Complex Space".* (First of three Special University Lectures in Mathematics. Further lectures on February 12 and 13.)

College of Preceptors (in association with the School Nature Study Union, at 2 and 3 Bloomsbury Square, London, W.C.1), at 6 p.m.—Miss M. Hollings: "Should a Teacher of Natural History be Bound by a Syllabus ?"

Society of Instrument Technology, Data Processing Section (at Manson House, Portland Place, London, W.1) at 6 p.m.—Mr. L. Airey: "A Digital Instrumentation System for Use in the Testing of Jet Engines".

Society of Chemical Industry, Corrosion Group (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Mr. S. C. Britton and Mr. K. Bright: "Recent Research on the Corrosion of Tinplate".

Thursday, February 12

Institution of Chemical Engineers (at Church House, Westminster, London, S.W.1), at 9.30 a.m.—Symposium on "Mass Transfer".

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Prof. A. Haddow, F.R.S.: "The Chester Beatty Research Institute".

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. J. L. Monteith: "Micro-meteorology in Relation to Plant and Animal Life".

Royal Institution, Library Circle (at 21 Albemarle Street, London, W.1), at 5.30 p.m.—Mr. James Lawrie: "Reading about Science".

Royal Aeronautical Society (at the Institution of Mechanical Engineers, Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Mr. W. H. Stephens: "Earth Satellites".

Chemical Society (in the Large Chemistry Lecture Theatre, Imperial College of Science and Technology, South Kensington, London, S.W.7), at 7.30 p.m.—Prof. E. R. H. Jones, F.R.S.: "Polyacetylenes" (Pedler Lecture).

Friday, February 13

British Psychological Society, Occupational Psychology Section (in the Department of Psychology, Birkbeck College, Malet Street, London, W.C.1), at 1 p.m.—Dr. J. B. Parry: "The Place of Personality Appraisal in Occupational Selection" (Chairman's Address).

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Anniversary Meeting (followed by Annual General Meeting).—Dr. W. H. Steavenson: "The Instruments of Sir William Herschel" (Presidential Address).

Institution of Mechanical Engineers (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Prof. F. K. Bannister: "Induction Ramming of Small High Speed Air Compressor".

British Institution of Radio Engineers, Medical Electronics Group (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6.30 p.m.—Mr. Peter Styles: "Some Instrumentation Problems in Medical Electronics with particular reference to Electromyography".

Antiquarian Horological Society (at the Science Museum, South Kensington, London, S.W.7), at 7 p.m.—Mr. F. H. Knowles Brown: Illustrated lecture on "The A. H. S. Tour in Switzerland, June 1957".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. Harry Godwin, F.R.S.: "The History of the British Flora".

Saturday, February 14

Biochemical Society (in the Beveridge Hall of the Senate House, University of London, W.C.1), at 10.30 a.m.—Symposium on "The Biosynthesis and Secretion of Adrenocortical Steroids".

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Mr. Norman Cook: "Unearthing London".*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Inspectors of Fisheries (5) (with a degree or equivalent in zoology, plus an adequate knowledge of botany) in the Department of Lands, Dublin—The Secretary, Civil Service Commission, 45 Upper O'Connell Street, Dublin, Ireland (February 13).

Technician (with workshop and preferably previous hospital experience) in the Physics Department—The Administrative Officer, Marie Curie Hospital, 66 Fitzjohn's Avenue, London, N.W.3 (February 13).

Biometrician in the Department of Research and Specialist Services—Ministry of Agriculture, Federation of Rhodesia and Nyasaland, for duties which will include the design of experiments in all phases of agriculture and animal husbandry research, together with the analysis of data and related statistical practice—The Secretary (R), Rhodesia House, 429 Strand, London, W.C.2 (February 14).

Lecturer or Assistant Lecturer in Mechanical Engineering—The Registrar, Manchester College of Science and Technology, Manchester 1 (February 14).

Assistant Lecturer (qualified in either pure or applied mathematics) in Mathematics—The Registrar, University College of North Staffordshire, Keele, Staffs (February 16).

Senior Lecturer (suitably qualified man or woman) in Radiochemistry at the College of Technology, Liverpool—The Director of Education, 14 Sir Thomas Street, Liverpool 1 (February 20).

Leverhulme Research Fellows (2) in Radioastronomy—The Registrar, The University, Manchester 13 (February 21).

Assistant Lecturer (veterinary surgeon or with a degree in physiology) in the Department of Physiology—The Secretary, Royal Veterinary College (University of London), Royal College Street, London, N.W.1 (February 28).

Assistant (science graduate, preferably with qualifications in physiology) in Clinical Chemistry—The Secretary, The University, Aberdeen (February 28).

Fellow (preferably with a Ph.D. degree in physics or metallurgy or equivalent research experience in these fields) in Metal Physics, Division of Tribophysics, C.S.I.R.O., Melbourne, Australia, to study crystal defects and the mechanism of plastic deformation—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Appointment No. 370/123 (February 28).

Lecturer in the Department of Astronomy—The Secretary, The University, Edinburgh (February 28).

Imperial Chemical Industries Research Fellows in Chemistry, Biochemistry, Physics, Engineering, Chemotherapy and related subjects—The Secretary, Academic Council, The Queen's University, Belfast (March 1).

Principal—The Secretary, The Royal College of Science and Technology, George Street, Glasgow, C.1 (March 1).

Botanical Artist (Research Assistant II) (with a knowledge of plant form equivalent to that required at G.C.E. (Advanced Level) and preferably art training to the level of National Diploma in Design), to make plant models and illustrations—The Secretary, National Museum of Wales, Cardiff (March 6).

Research Fellow or Fellow in the Department of Statistics, Research School of Social Sciences, Australian National University, Canberra, for work in the field of mathematical statistics and its applications to other sciences—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, March 16).

Principal (with high academic qualifications and appropriate educational and administrative experience)—Clerk to the Governing Body, Northern Polytechnic, London, N.7 (March 31).

Assistant or Associate Professor (with an honours degree in mathematics and preferably some postgraduate experience in research or teaching) in the Department of Mathematics—Head of the Department of Mathematics, University of New Brunswick, Fredericton, N.B., Canada.

Assistant Statistician (with an honours degree in statistics, or in mathematics with a diploma in statistics, and desirous of working in the fields of biology or medicine) in the Medical Research Council's Pneumoconiosis Research Unit, Cardiff—The Director, Pneumoconiosis Research Unit, Llandough Hospital, near Penarth, Glamorgan.

Assistant Professor of Chemistry, to teach physical chemistry up to honours degree standard—The President, Memorial University of Newfoundland, St. John's, Newfoundland, Canada.

Freeland Chair of Chemistry—The Secretary, The Royal College of Science and Technology, Glasgow.

Geologist (with an honours degree in geology or equivalent qualification, special qualifications in ore mineralogy, and postgraduate experience in handling problems of ore genesis and ore microscopy), for duties chiefly concerned with laboratory work in Copenhagen, and also a certain amount of field work in Greenland—The Director of Survey, Grønlands Geologiske Undersøgelse, Østervoldgade 7, Copenhagen K., Denmark.

Head of the Department of Physics—Chairman of the Staff Committee, Essex College, Assumption University of Windsor, Windsor, Ontario, Canada.

Junior Scientific Officer (male or female, with an honours degree in science, pharmacy or biology), for duties consisting of technical work in the Blood Transfusion Service Laboratories—The Director, Blood Transfusion Service, Roby Street, Manchester 1.

Laboratory Technologist (male or female, A.I M.L.T., and preferably experience in serological techniques and tissue culture connected with virology) with the West African Council for Medical Research (Virus Research Unit, Yaba, Nigeria)—The Crown Agents, 4 Millbank, London, S.W.1, quoting Ref. M.3C/52407/NF.

Plant Physiologists (2) (with a good honours degree in botany or natural science with two years suitable postgraduate training or experience) at the West African Institute for Oil Palm Research, Nigeria; one to review present methods of production and initiate ways of increasing the supply of palm oil, and the other to carry out leaf analysis and other investigations into the nutrition of the oil palm—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.197/199/013.

Senior Lecturer (preferably with a higher degree in chemical engineering and several years teaching experience at university or technical college level) in Chemical Engineering at the University of Mandalay, Burma—The Ministry of Labour and National Service (E.9), 26–28 King Street, London, S.W.1, quoting A.12/BUR/TCS/217.

E·I·L

The VIBRON

is a new electronic component, which replaces the electrometer valve in the measurement of very small currents.

The VIBRON is a vibrating condenser unit which, in a suitable circuit, can measure currents as small as 10^{-15} ampere, or resistances as high as 10^{15} ohms, to an accuracy of ±2% and with a zero stability of ±100 microvolts in twenty-four hours. It can be supplied as a unit for building into instruments of your own design, or, alternatively, VIBRON instruments of several types are available from E.I.L.: the Model 33B Electrometer shown here is an example.

Manufactured under British Patent Nos. 550610 and 774116.

ART AND SCIENCE OF MANAGEMENT

At a conference recently organized by the National Institute of Psychology, some ex-Service officers described their attempts to obtain posts in industry and commerce and their subsequent experiences. What surprised them most was the oft-repeated statement that, to be successful in industry, they would first have to unlearn all that they had ever been taught in the Services. Yet, by common consent, the qualities which would enable them to make headway were those that had become part and parcel of their behaviour because of the training they had received in the Forces. The systematic approach to a job, the discarding of the irrelevant and concentration upon the essentials became second nature to men who were steeped in the Service way of life. It is not surprising that these qualities are proving successful in civilian life and that, in the main, officers declared redundant by the Government's changed defence policy are not finding it particularly difficult to obtain suitable openings. These openings, however, are mainly in those companies which already have a proved record of success and are outstanding in their particular fields of activity. They are companies which have systematically developed the right kind of administration pattern to suit their organizations and have selected and developed their executive staff along equally systematic lines. These companies, unfortunately, are but a small proportion of those in British industry as a whole, and, by contrast, give prominence to many present defects and deficiencies.

Since the War the defects and deficiencies have been largely hidden by the boom period which has been called the seller's market. Now that products have to be sold as well as made, industry is becoming more and more aware that its greatest lack is of executive staff with qualities fitted to meet a challenge with which it has not hitherto been confronted. Despite the attention paid to executive development since the War, the large majority of managers in British industry are still men who have succeeded to their posts by their ability to stay in one position longer than other candidates; they have outlived their competitors. Despite the mildness of the present recession, many of them are bewildered by the too rapidly changing conditions, and lack the flexibility to overcome them.

By and large, these managers entered industry in days when the more intelligent and better-educated members of the community chose their careers among the professions. Many of the older managers were recruited from 'black-coated' workers and, as David Lockwood has pointed out*, obtained managerial positions by dint of their proximity to the employer, their superior literacy compared with manual workers, their knowledge of the firm's secrets and its financial affairs, and the tradition which decreed that office workers were more capable of running the business than men drawn from the shop floor. With the relative decline in status and prestige of the clerk, due to the spread of literacy among all sections of the community, as well as the long-overdue recognition of the place of the technologist and technician in industry, it is unlikely that the managers of the future will be drawn from the same sources as hitherto or trained in the same way. They will, in the main, come from the universities and the senior technical colleges, and their training will be consciously organized and much more concentrated.

How they are to be trained is a matter of considerable conjecture, and no fixed rules are likely to be prescribed. The traditional British dislike of 'theory' and strong preference for practical problems, the prejudices of many responsible business leaders who reached their positions 'the hard way' and believe that there can be no other, the fear that young men who study the art and science of management may become over-impressed with their own theoretical knowledge and ignore the wide variations in human behaviour, all [tend to preserve the *status quo*.

Of those who believe that management has developed a body of knowledge which can be taught and at a comparatively early age, probably the most able British advocate is Lyndall F. Urwick, chairman of Urwick, Orr and Partners, Ltd. In a privately published pamphlet*, Urwick argues that, in sharp contrast to its regard for the 'practical', the main opposition to the more formal teaching of management in Britain springs from our regard for the amateur. "Being a Director—and 'Director' is as yet the only title carrying social prestige which business and the outside world has recognized—is still, in part, a stronghold of the amateur. Many men are made directors of companies who have neither worked their way up through the ranks of management nor have qualified themselves professionally in other ways, . . . that they have any knowledge of the art and science of management or of the technique of the particular industry or trade with which the Company is concerned, they would be the last people to pretend." Having achieved control of a business through family or social connexions, they look askance at those who suggest that future directors and managers shall have professional qualifications and some knowledge of the art and science of management.

---

* "The Black-coated Worker" (Allen and Unwin, 1958).

* "Is Management a Profession?" (Urwick, Orr and Partners, Ltd., 29 Hertford Street, London, W.1, 1958).

Despite all the opposition engendered by custom, fear and prejudice, however, Urwick's views are increasingly finding support in British industry and commerce. Instead of learning the skills of management pragmatically over a long period of years, it is becoming clear that the Americans are not wholly wrong, and that there is a body of knowledge which can be taught, as is being done so successfully throughout the United States to-day. It is also becoming recognized that merely to provide short courses for older men is unsatisfactory and inadequate; many of the men who have attended such courses have been unable to profit by them and, as subsequent experience has shown, have returned to their companies with a surface accretion of knowledge which their set ways have made them unable to assimilate. There is a body of knowledge which must be taught when a potential manager is in his formative years. Some can be taught as part of his initial degree courses; much would better wait until he has had a few years doing a management job.

This does not mean that senior managers of the future will be selected for their 'knowledge about' management. In Urwick's own words, "Management is primarily a question of leadership. And leadership, while it can be refined and improved by experience under wise guidance, depends ultimately on the possession of certain qualities of character . . . all responsible people who advocate that management should become a profession are clear that practical experience is the most important element in the development of professional competence. Practical arts cannot be learned from books or lectures. They can only be learned by practice, by knowledge of and acquaintance with the occupation".

What systematic study can do is to make the process of 'learning by experience' more fruitful and more effective. Through books a young student of management can be made more reflective about his experience, can grasp more quickly and clearly what is happening around about him in factory and office. Books and study also help to systematize his experience, to make him more aware of what is lacking and enable him to fill the gaps. By referring the petty details of his early work as a junior to general principles, learning by routine becomes less uninteresting. In this way the well-founded training by apprenticeship will be strengthened when it is made more systematic and supported by theoretical requirements.

Unless the existing methods of training managers by learning on the job is supplemented by a considerable extension of theoretical studies provided by universities and senior technical colleges, British industry is unlikely to meet successfully the challenge before it. The greatest obstacle to progress in British industry is still a body of management which bases its thoughts and actions on traditional practices inherited from its predecessors. Rule-of-thumb must give way to an approach based upon scientific method and, in the present state of British industry, since this is unlikely to be caught, it must be taught.

MARINE ECOLOGY

Marine Ecology

By Prof. Hilary B. Moore. Pp. xi+493. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1958.) 76*s*. net.

THERE has long been need for just such a book as this and which Prof. Hilary Moore is admirably fitted to write. His experience ranges in latitude from Millport by way of Port Erin, Plymouth and Bermuda to Miami and so also covers both shores of the North Atlantic. His research has been equally wide, from his illuminating early studies on intertidal barnacles, dog-whelks and sea urchins, to examination of bottom deposits and of the deep scattering layer. Further, he writes with commendable clarity.

His book is well arranged, leading from description of environmental factors, physical, chemical and biological, to a consideration of habitats, from the abyss to the surface, while the second half of the book is devoted to the organisms which inhabit these environments and are controlled in distribution by these factors. The reader cannot but be impressed, and if he is himself a worker in this general field perhaps a little depressed, by the wealth of information now flooding in from autecologists and synecologists, from physical and chemical oceanographers, from fisheries biologists and statisticians, all of which must in some manner be synthesized. Indeed this is the concluding note of the book, the need for more reviewing and co-ordination of existing information.

Inevitably such a book, even running as this one does to 420 pages of text apart from appendix, references and index, represents the result of selection, and many may feel that more attention should have been paid to matters of particular interest to themselves. Certainly the list of references, though running to twenty-seven pages, is very far from complete. But Prof. Moore would not claim that it was or could be. I feel that more might reasonably have been made of estuarine conditions, including regions of low salinity like the Baltic and Caspian Seas, and especially regret there is no mention of the unique environment and population of mangrove swamps. But it is gratifying that adequate attention is paid to the biological, as distinct from the geographical, aspect of coral reefs.

Among the major impressions which emerge is the realization of how often, in the plankton, on the bottom, on the shore and in the mixed salinities of estuarine waters, it is the organisms themselves which represent the best criteria of environmental conditions. As Prof. Moore points out, the precise nature of the significant environmental factor or complex of such factors often either eludes the observer or else defies adequate measurement.

The wealth of information to be digested in preparing this book doubtless explains why it is a little out of date; there are few references much after 1950. Certainly an author must know when to stop, but it is a pity that more of the recent work on barnacles, where Prof. Moore was so notable a pioneer, has not been included, and there is no mention in the sections dealing with vertical migration of plankton of the highly significant work of Prof. J. E. Harris. But careful reading reveals few errors, although the influence of copper on settlement of oyster larvæ mentioned on p. 95 is surely no longer accepted and there appears to be a misreference to the subject-matter of Table 9–2 on p. 311. Misprints are commendably few in an extremely well-produced and fully illustrated book which does credit to both author and publisher. The sole drawback is the price, which it is hoped will prevent no institution from adding this book to its library. Marine biologists in general should buy it if they can, but in any event should most certainly read it. C. M. YONGE

GEOGRAPHICAL CLIMATOLOGY

The Climate of New Zealand

A Geographic Survey. By B. J. Garnier. Pp. 191+12 plates. (London: Edward Arnold (Publishers), Ltd., 1958.) 70*s*. net.

THIS superbly produced and distinctly expensive account of the principal features of the climate of New Zealand is derived in the main from numerous papers in scientific journals. Prof. B. J. Garnier, formerly of Otago and now at Ibadan, asks his readers to regard the volume primarily as an exposition of an important aspect of the country's geography and secondarily as an attempt to show how studies in systematic geography may make their particular contribution to the field of learning.

Like many geographers, he is evidently rather conscious of his subject and the occasional lapses into the jargon of geography are tiresome. "The overall climatic picture of eastern North Island is one in which some diversity is held together in a framework of common distinguishing elements . . . a remarkable quality of the area as a geographic entity is the way this pattern is repeated by other features" (p. 107) will be well understood by students who have been subjected to this sort of thing, but if they want to know about the climate they may still refer with profit to Kidson's ten beautifully concise pages in *The Quarterly Journal of The Royal Meteorological Society* for 1937. Phrases such as "As its name implies, northern New Zealand is the most northerly of the climatic regions" (p. 71); an "influx of influences" (p. 142) are infelicitous. Fortunately, like the southerly rainstorms, these affectations do not last long. There are many agreeable descriptive passages, and in a work on climate the many references to the physical background and the regional characteristics of the vegetation and soil are most welcome; for example, the admirable paragraphs of plant geography on p. 130. The illustration of a summer cold wave is excellent (pp. 118–9).

Beginning with a broad survey of New Zealand's climatic qualities and a discussion of how these have been produced by the combined effect of its position and physiography, the author then defines his climatic regions and in nine chapters discusses their characteristics. The splendidly chosen landscape photographs are a most attractive feature; maps and diagrams abound; synoptic situations and monthly sequences of daily maxima and minima are well displayed; there are useful tables, an extensive bibliography and an index. With its fine assemblage of references, this work is perhaps to be regarded as a regional geography rather than a text on climate; for the present reviewer could find no information about the absolute extremes of temperature, no clear definition of the snow-line, no comment about the marginal qualities of Mt. Egmont, nothing on the climate of Stewart Island; no comment on the astonishing freedom from screen frost at Wellington (p. 170) which, incidentally, makes the averages on p. 169 look a little odd. For the British reader there is no clear indication of how often snow either falls or lies; no map locating the stations; no detail about the frequency of thunderstorms. To say that conditions of permanent frost prevail on the high summits in North Island (p. 126) begs the question. Estimated lapse-rates of temperature in Appendix *A* are not related to upper-air data; and we hear nothing about the extent, if any, of climatic fluctuation in recent times. Rainfall reliability and also evapo-transpiration, a concern of many geographers, receive useful notice. To the regional geographer studying New Zealand as a whole this book, with its abundance of references, extracts, tables and maps, will have many virtues. It is costly, but can be a useful and indeed desirable acquisition to a library.

GORDON MANLEY

TROUBLED WATERS

An Introduction to Fluid Dynamics

By Dr. F. J. Bayley. Pp. viii+215. (London: George Allen and Unwin, Ltd., 1958.) 28*s*. net.

An Introduction to Fluid Dynamics

By Prof. G. Temple. Pp. xi+195. (Oxford: Clarendon Press; London: Oxford University Press, 1958.) 25*s*. net.

Proceedings of the Fifth Midwestern Conference on Fluid Mechanics

Held at the University of Michigan, April 1 and 2, 1957. Edited by Prof. A. M. Kuethe. Pp. viii+388. (Ann Arbor, Michigan: University of Michigan Press, 1957. Published for The Engineering Research Institute, Ann Arbor.) 8 dollars.

THE three volumes under review cater for different sections of the scientific community. Dr. Bayley aims at helping undergraduates in the engineering faculties while Prof. Temple's work is intended primarily for students reading honours mathematics or physics. The proceedings of the Fifth Midwestern Conference on Fluid Mechanics will appeal mainly to the research worker.

The introduction to fluid mechanics provided by Dr. Bayley is unsatisfactory. He has tried to write a simple book covering a wide field. This is extremely difficult to do, especially in two hundred pages, for it demands terse, lucid instruction. Unfortunately in this book the insistence on brevity has led to many vague statements and errors of omission. For example, the paragraph on units will do more to confuse than illuminate the situation. Such a text should surely start with a clear explanation of the three systems of engineering units in current usage and the relations between them. The chapter on fluids at rest contains no mention of floating bodies, and the presentation of the immensely powerful momentum equation is quite inadequate. Moreover, the compressible form of Bernoulli's equation is derived using $p = k\rho^{\gamma}$. This can easily lead students to believe that the equation holds only for this type of flow. Later in the book Dr. Bayley does present the general energy equation both simply and accurately.

Dimensional analysis receives the prominence it deserves and the principle is demonstrated in a number of well-chosen examples. The most successful chapters deal with pipe flow, channel flow and fluid machinery, but the discussion of flow over immersed bodies is poor. The role of viscosity in the production of lift and drag and the concepts of circulation and an ideal fluid are not clearly explained. It would have been better to have left these tasks to a more specialized text.

The book is attractively presented but some diagrams need alteration; for example, Fig. 9.5 purports to show the pressure distribution around an aerofoil section. There is no scale and in fact the body is an airship hull. There are a few references but no bibliography.

In contrast, the book with the identical title by Prof. Temple is rigorous in treatment and narrow in scope. He says in the preface that "the emphasis in fluid dynamics is no longer on analytical solutions of ingenious problems but on the development of the physical significance of the fundamental principles". Yet his book is not only limited to the theoretical aspect of fluid dynamics but also to the treatment of a perfect fluid deprived of viscosity and compressibility. As an introduction to fluid flow for mathematicians and physicists this is too severe a restriction. Viscosity and compressibility are the two most important properties that a fluid possesses. Unless their importance is realized and used as a guide to useful mathematical solutions, wholly misleading flow patterns based on the ideal fluid concept can result. Prof. Temple could avoid much criticism by re-naming the book "a monograph on the ideal fluid".

After deriving the momentum and energy equations a chapter is devoted to applications of Bernoulli's theorem. The compressible form of this theorem is again derived using "the adiabatic law $p \propto \rho^{\gamma}$", a doubly misleading treatment and the sole mention of compressibility. The existence of a velocity potential is rigorously established, then the method of building potential flows is explained and demonstrated by numerous examples. Among these is the circular cylinder with Thwaites flap. Here the connexion between theory and the behaviour of a real viscous fluid is clearly stated; moreover, the reference to the original work is given. Conformal mapping is used to find the continuous flow around the flat plate, circular arc and usual Joukowski profiles. This is followed by a section on discontinuous flow where the Helmholtz patterns are contrasted with the continuous flow results and the lifts and drags compared. One looks in vain, however, for the vital experimental evidence. The short last chapter is on incompressible slender body theory, the accuracy of which is well illustrated by comparison with the exact potential flow solution for the flow around an ellipsoid.

The whole book is well provided with references and there is a valuable bibliography to which the reader must refer for a more complete and clear picture of fluid dynamics.

Nowadays nearly every conference eventually publishes the papers presented in book form. The Fifth Midwestern Conference on Fluid Mechanics held at the University of Michigan on April 1 and 2, 1957, is no exception. This volume contains twenty-six of the original thirty-two papers.

Since they are nearly all of a specialized nature but on widely different aspects of fluid mechanics this method of presentation seems unwise. Few individuals will relish paying eight dollars for a collection of short reports, only a few of which are of immediate interest to them. Perhaps the book is aimed just at the libraries.

There are, of course, many interesting papers in the eleven sub-sections: stability of flows (3 papers), laminar flow (2), turbulent flow (6), supersonics (2), hypersonics (3), magneto-gasdynamics (1), gas jets in liquids (1), slider bearings (1), free surface (3), marine applications (2) and general (2). Among the authors are Henry Görtler, Lester Lees, Max Munk and S. I. Pai. All the papers are necessarily brief but include an abstract, introduction, brief description and conclusions. All are well provided with references and clearly set out. The figures are first-rate and the whole book beautifully photolithoprinted. The greatest criticism is that no discussion is included. Often at a conference the papers presented provoke important comment and bring to light additional information. All this is lacking, and one is left with the feeling that there must be a better way of distributing conference data to a wider public. J. L. STOLLERY

MORE PROGRESS IN NUCLEAR ENERGY

Progress in Nuclear Energy

Series 1: Physics and Mathematics, Vol. 2. Edited by D. J. Hughes, J. E. Sanders and J. Horowitz. Pp. vii+375. (London and New York: Pergamon Press, 1958.) 90*s.* net.

FAIRLY soon after the first Geneva Conference on the Peaceful Uses of Atomic Energy there was a spate of books and journals containing, so the publishers said, carefully written reviews of the vast amount of information released at that momentous meeting. In some cases the claim was justified; in others the publications were merely collections of the actual Geneva Papers with precious little editorial comment, and it is to be hoped that this sort of thing will not happen after the recent second Conference.

The first volume in Series 1 (Physics and Mathematics) of "Progress in Nuclear Energy" was, by and large, to be included in the first group and fully justified the publisher's claims. It had some very useful survey articles, particularly, one remembers, on the properties of fissile material.

The second volume in the series has now appeared and is well up to the standard of the first. The articles are again detailed and quite hard going even for the specialist reader. Allen and Henkel open this new collection with an article on the interaction of fast neutrons with thorium, uranium and plutonium. The behaviour of low-energy neutrons with various heavy nuclei is covered by Harvey and Schwartz, and these first two articles continue the useful collection, started in Vol. 1, of the data on cross-sections which are relevant to reactor design.

In reactor physics there is little point in having extensive data on neutron cross-sections unless information is available also on the energy spectra of neutrons in reactors. Precise measurement and calculation of these are difficult, but are being tackled in several laboratories, and the article by Poole, Nelkin and Stone on the "Measurement and Theory of Reactor Spectra" is very opportune.

Until quite recently there have been large discrepancies between the nominal values of the standard neutron sources used in different countries. However, a little international co-operation seems to have improved the position and there is now agreement in most cases to about 1 per cent. The present situation is reviewed by Richmond in an article which gives information also on the procedures used for calibration. Sources used as standards are usually based on alpha or gamma emitters, although spontaneous fission sources are now being tried.

For studies in neutron physics, sources using particle accelerators are very valuable, particularly as they can be pulsed. The use of pulsed sources in measurements on neutron diffusion is discussed by von Dardel and Sjöstrand in the fifth chapter of this new volume.

The last three chapters are concerned almost exclusively with theoretical aspects. The penultimate chapter, by Hassitt, is on the methods of calculation for heterogeneous reactors, and preceding it is a long discussion of the special problem of resonance escape probability. As the editors state in their preface, the methods of calculation take advantage of developments in computers and this is very evident in the final chapter on "Monte Carlo Methods in Transport Problems".

Altogether this is a nicely balanced collection of valuable articles. J. Walker

THE GREEN FLASH

The Green Flash and Other Low Sun Phenomena

By D. J. K. O'Connell, *S.J.* Photographs by C. Treusch, *S.J.* Pp. 192 (24 plates). (Castel Gandolfo: Specola Vaticana, 1958. Distributed by North Holland Publishing Company, Amsterdam; and Interscience Publishers, Inc., New York.) 45*s.*

The Sun, when close to the horizon before setting, may appear oddly distorted in shape, its upper rim showing traces of green colour while its lower portion is red. As the last segment of the upper rim approaches the horizon, pronounced green coloration may spread from its edges to fill the segment for the few seconds before it vanishes below the horizon. Much more rarely, at the instant when the last segment disappears below the horizon, a green flash may be observed to dart upwards at the point of disappearance. This is not an after-image, the green complementary colour subjectively following the sudden removal of the normal red at sunset, for it may be observed also at sunrise. It occurs when refraction in the atmosphere close to the Earth's surface is abnormally great, that is, when the density decreases rapidly with height. If Rayleigh scattering removes light of shorter wavelength than the green and absorption by water vapour and oxygen is effective in the orange and yellow, then the remaining colours red and green will be so separated by the abnormal refraction that the green will persist for a short period after the red has gone and the transition will be abrupt.

The Vatican Observatory, situated in the Alban Hills at a height of 450 m. with a western horizon at a distance of 80 km. over the Mediterranean, is well situated for a study of these phenomena. The many fine plates in colour and in black-and-white that appear in this volume show how successfully the very difficult tasks of photographing these evanescent effects and of reproducing them here in colour have been achieved. The techniques that were developed in using the Observatory telescopes are fully described, and detailed notes of description and analysis accompany each photograph along with meteorological and other relevant data. There are also some photographs of the green flash at sunrise over land, of the green rim of the setting Moon and of Venus and of experiments with artificial sunsets and layers of discontinuity.

While the author states that the main purpose of the book is "to provide observational material rather than to discuss the various phenomena exhaustively", he provides an interesting account of the history of this subject—it is surprising to learn that the earliest recorded observation of the flash that he deems authentic was made in 1865—a lucid, though brief, account of the theory with an examination of the factors that influence the characteristics of the phenomenon, and a comprehensive bibliography.

James Paton

ECOLOGY AND ECONOMICS OF AGRICULTURAL GEOGRAPHY

American Agriculture

Geography, Resources, Conservation. By Prof. Edward Higbee. Pp. x+399. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1958.) 64*s.* net.

This work is essentially a panoramic description of farming in the United States. The author's obvious interest in soil and water conservation has led him to adopt an ecological, or at least a biogeographical, approach. This gives a refreshing unity to what might otherwise have been a discursive and disjointed book.

Part 1 is a short and elementary but useful introduction to the relations between climate, soils, natural vegetation and 'land capability'. Part 2 is about the dry western half of the United States, where water is the primary limiting factor to agricultural production. The author shows very clearly how the vast irrigation schemes of the Central Valley of California and other western 'valley oases' depend on the control of both soil erosion and floods in the western mountain States. This, in turn, depends on good forest and grazing management in the non-irrigated areas. It affords an excellent example of the value of large-scale ecological integration in agriculture and forestry. Such integration calls for the planning of land and water use on a semi-continental scale. This, in its turn, raises political and social difficulties, which the author mentions; wisely, however, he refrains from offering solutions. Then, after a glimpse at the Pacific North-West, Prof. Higbee crosses the dry Great Plains, where the statistical expectation of drought dominates year-to-year changes in wheat yields and hence the structure of the local agricultural economy.

Part 3 deals with the humid and more complex eastern half of the United States. Here topography, local types of soil, and drainage problems are more important limiting factors than shortage of water, even though sprinkler irrigation is obviously rapidly increasing, particularly in market-gardens and on pastures. The corn (maize), dairy, cotton, and other types-of-farming 'belts' are successively outlined. The emphasis is perhaps more economic and less ecological than it was in Part 2, but these chapters are enhanced by some useful case studies of well-conserved farms.

The book is well illustrated, even though some of the many maps are too small to be readable. There are perhaps more tables of economic statistics than are really necessary. Further, the book ends somewhat abruptly and unexpectedly in a cranberry bog in Martha's Vineyard, Massachusetts. It lacks a concluding statement.

This is unfortunate. For it is clear to one who has visited nearly all the areas described by the author that his descriptions and bio-geographical analyses are accurate and perceptive. It would have been helpful to know what ecological and economic principles suggested themselves to his mind as a result of this most interesting and informative survey of American agriculture.

A. N. DUCKHAM

SCIENTIFIC APPLICATIONS OF SCIENCE

Operational Research in Practice

Report of a NATO Conference. Edited by Max Davies and Michel Verhulst. Pp. ix+201. (London and New York: Pergamon Press, 1958. Published for and on behalf of Advisory Group of Aeronautical Research and Development, North Atlantic Treaty Organization.) 84s. net.

IN setting up what was to become the first so-designated Operational Research Section in Fighter Command, Watson-Watt was the first to achieve the most thorough application of science itself. Radar was entirely new, and the momentum of its application carried the scientist into the heart of tactics and strategy. So it was that his formulation of the duties of operational research sections remains valid even until to-day, as Sir Solly Zuckerman emphasizes in his introduction to the report of this North Atlantic Treaty Organization conference.

But how has operational research fared since then ? It is still firmly embedded in military practice, despite the shift of emphasis from current operations to future ones, the evaluation of exercises and the development of war games. Here, due to the speed of innovation, there is little scope for hardening into conventional wisdom (to borrow from Prof. Galbraith) in regard to the conduct of military operations, the conventional wisdom of war itself being the accepted framework. But some important applications of operational research were in fields where past procedures, at one time relevant, provided the precedent. Within the Armed Services the civilian scientists were able to make a break-through, perhaps because they were unaffected by conventional wisdom.

Immediately after the Second World War the scope for scientists seemed as wide as human activity itself. The prevailing mood is now more sober, as shown by thoughtful contributions on decision-making and war games, both in civil and military situations, with the need for a theoretical rationale. Logistic and transport problems are shown to have the same basic structure, but let the user beware of an uncritical borrowing of technique, for seemingly slight differences might turn out to be important.

There is, however, one extremely important difference. In civil applications (as quoted) a 1 per cent increase in efficiency (as measured by gross profits) leading to an increase of 5 per cent in distributed profit is an achievement that firms are willing to pay for—whether or not it represents a good national use of scarce man-power. The reaction of a professional soldier is that "in a military context such improvements were seldom ever meaningful or worthwhile". He continues: "The application of operational research principles to operational research was highly desirable, but all too rare". I know of no university where an expert in "tensions in industry" from the sociology department has been invited to report on the tensions within the university.

CECIL GORDON

BACTERIAL POPULATION STUDIES IN THE CHEMOSTAT

The Dynamics of Bacterial Populations maintained in the Chemostat.

By Hermann Moser. Pp. iv+136. (Publication No. 614.) (Washington, D.C.: Carnegie Institution of Washington, 1958.) Paper, 1.15 dollars; Cloth, 1.40 dollars.

THE study of the mechanisms by which bacterial populations become better fitted to a given environment is of considerable fundamental importance. Of the various methods available for the study of such problems those using a continuous culture apparatus are especially valuable since the cells can be maintained in a state of active growth under defined conditions. In the simplest kind of continuous-culture apparatus the nutrient medium in the culture tube is automatically renewed and immediately a portion of the bacterial suspension is removed, thus maintaining (after a certain time of operation) a steady state. The chemostat superimposes another form of control on the growth, by keeping the concentration of one of the constituents of the growth medium at a sufficiently low level so that the bacterial population grows at a reduced rate which is a direct function of this concentration and is independent of all other nutrient factors.

Although the fundamental theory of growth in the chemostat has been presented by other workers, whose contribution the author generously acknowledges, the genetic theory of populations, it is claimed, has not been presented in a satisfactory way. This task the author has set himself and he proceeds to predict and discuss "the various patterns in which mutants of different kinds may accumulate in a continuously growing population and the ways in which genetic equilibria are attained in such populations". He maintains that "since we are dealing with non-sexual bacteria, the sole factors influencing the frequency of mutants in the population to be considered are the capacity to mutate, and selection". He considers both specific and periodic selection.

On the basis of these assumptions the author proceeds to set up a population model and to examine in considerable mathematical detail the numerous aspects of the problem. The mathematical treatment is the most comprehensive the reviewer has seen and it is recommended to anyone interested in this subject. However, the reviewer feels that it is a pity that the fundamental assumptions of mutation followed by selection were not more rigorously confirmed. It would have provided a better balance if the complementary mechanism of adaptation by non-genetic means had been considered (if only to be rejected), especially since the theory of periodic selection has been challenged for at least one example.

The book is well written and is produced to the usual high standard of the publications of the Carnegie Institution of Washington.

A. C. R. DEAN

SCIENTIFIC CO-OPERATION WITHIN THE BRITISH COMMONWEALTH*

By H.R.H. THE DUKE OF EDINBURGH, K.G., K.T., F.R.S.

WE often hear about the invisible ties of friendship and trust which bind together the members of the Commonwealth. We do not hear quite so much about the practical advantages of membership or the amount of quiet unspectacular work which is going on to the mutual benefit of the Commonwealth as a whole. I must admit that it came as quite a surprise to me to discover the amount of useful co-operation in science which is going on within the Commonwealth to-day. I was also delighted to find that this co-operation has been active for quite a long time. It is always the same, and I am sure many have also noticed that there is no better way of finding out about a subject than having to speak about it.

Conferences

One of the first things I discovered was that this address, the subject of which you chose for me, has come at a most appropriate moment because the very first formal step in scientific co-operation was taken exactly fifty years ago. In the year 1909 the Entomological Research Committee for Tropical Africa was formed with headquarters at the British Museum (Natural History), London. The funds came from the African Colonies and the United Kingdom, and it made the first systematic collection and study of insects injurious to men, animals and crops in East and West Africa.

Although this was a very modest venture—the annual budget only amounted to £2,000—yet it was the start of great things.

The venture was discussed at the Imperial Conference of 1911, and in 1913 it became the Imperial Bureau of Entomology, with two main functions: (1) "the identification of all injurious insects sent in by officers attached to departments of Public Health in countries in the Empire"; (2) "to issue a monthly periodical giving summaries of all current literature both British and foreign, dealing with noxious insects, whether agricultural pests or disease carriers". In the same year it published its first journal of abstracts.

Next, the Imperial War Conference of 1918 established the Imperial Bureaux (now the Commonwealth Institute) of Mycology at Kew, and it was the Imperial Agricultural Research Conference of 1927 that set up the first Commonwealth Agricultural Bureaux.

In 1933 the Imperial Committee on Economic Consultation and Co-operation met, and one of its decisions was that there should be a scientific conference every five years which, among other things, was to review the working of the Commonwealth Agricultural Bureaux.

It is therefore plain that this subject of Commonwealth co-operation in science has been given serious consideration for a good many years by many hard-headed and practical people. I also want to make it clear that throughout the story the endeavour has been to benefit the Commonwealth as a whole and not the particular interests of any one country.

Therefore, to resume the story. The first Commonwealth Scientific Conference and First Review Conference of the Commonwealth Agricultural Bureaux was held in London in 1936, and, as a result, two further Bureaux were added. Since then, there have been review conferences in 1946, 1950 and 1955. These concerned themselves mostly with finance and administration, but the last one recommended that the National Institute of Agricultural Engineering should compile and issue abstracts for Commonwealth use.

At the present moment there are three Commonwealth Institutes: the Commonwealth Institute of Entomology at the British Museum (Natural History); the Commonwealth Mycological Institute at Kew (where I opened a new building in 1955); the Commonwealth Institute of Biological Control at the Science Building in Ottawa. There are ten Commonwealth Agricultural Bureaux dealing with the following subjects: animal breeding and genetics at Edinburgh; animal health at Weybridge; animal nutrition at Aberdeen; dairy science and technology at Reading (which I visited in 1954); forestry at Oxford; helminthology at St. Albans; horticulture and plantation crops at East Malling (which I visited in 1957); pastures and field crops at Hurley (which I visited in 1958); plant breeding and genetics at Cambridge; soils at Rothamsted (which I visited in 1954).

Each Institute or Bureau is attached to an institute or laboratory or university department doing active work in that particular science.

A similar but separate undertaking is the Commonwealth Geological Liaison Office, which has been conducting a survey of the mineral resources of the Commonwealth for the past six years. Sixty-five reports have been issued, and the Office has now started to review the position of each of the minerals for the second time.

These organizations are probably the most practical and scientifically useful co-operative undertakings in the Commonwealth to-day. However, that is not the end of the story. At the 1930 Imperial Conference two committees were formed to go into the subject of industrial and fundamental standards. This resulted in the Standards bodies of the Commonwealth countries maintaining regular and systematic consultations, and in 1946 they met in conference in London and again in 1957 in Delhi. There is every reason to believe that they will go on meeting in future because their work has been most rewarding and is proving very valuable to science and industry as well as to Commonwealth trade.

The Second World War inspired the formation of the British Commonwealth Scientific Offices in London and Washington. In them work the Scientific Liaison Officers attached to the High Commissioners' or Ambassadors' staffs. They run themselves and a great many other things besides, and they are without any doubt the most lively force in Commonwealth scientific co-operation at this moment.

I must refer to five more conferences which between them have stimulated a new wave of thought and activity on this subject of scientific co-operation. In 1946 the Royal Society in London invited Commonwealth scientists to a conference in which they could speak as individual scientists. Immediately following this conference the Commonwealth Governments organized an official science conference where matters arising out of the Royal Society meetings could be discussed and official action taken. The reports of these two conferences make fascinating reading. First, because of the very obvious harmony and friendly spirit which existed throughout the discussions and, secondly, because of the immense scope of the discussions, which touched every possible aspect of Commonwealth scientific co-operation.

---

* Substance of an Address delivered at the Annual Meeting of the Pakistan Association for the Advancement of Science in Karachi on February 7.

The main topics of the discussions were: agricultural science; medical science; nutrition and special problems of the Commonwealth; mapping and exploration by air; scientific information services in the Commonwealth; interchange of scientists; co-operation with international scientific organizations; standards measurement; interchange of scientific material; land utilization and conservation; mineral resources of the Commonwealth; natural products and chemical industries which might use them; need for fundamental research; co-ordination of scientific work in Africa.

This last problem was considered at a special conference in London in 1949 and in Paris in 1950, and, as a result, the Commission for Technical Co-operation in Africa South of the Sahara, known as C.C.T.A., was formed. The members are: Belgium, the Federation of Rhodesia and Nyasaland, France, Portugal, the Union of South Africa and the United Kingdom. The Commission, among other things, convenes technical conferences, administers the Inter-African bureaux on various subjects, administers the Inter-African Research Fund and has established a number of advisory committees in various fields.

The third important conference was the Royal Society Scientific Information Conference of 1948 which, as its name implies, dealt with the problems of the collection, reproduction, abstraction and distribution of scientific information, particularly within the Commonwealth. This was, in fact, one of the first specialist conferences which had been recommended by the Royal Society meeting of 1946. The Conference suggested the formation of a Standing Committee on Information Services in order to "provide machinery for the interchange and coordination of ideas and information" which are emerging from the British Commonwealth as a result of the Conference.

The fourth Conference which is of particular interest was the British Commonwealth Scientific Conference held in Australia in 1952. I say particular interest because it was the first of this series of conferences attended by representatives from Pakistan and Ceylon. As to the business of the Conference I would like to quote a few sentences from the report: "The Conference felt that . . . the day to day contact of the liaison officers provided an effective system of collaboration which necessitated only occasional meetings of the heads of the official scientific organizations" and, later, "In addition to discussing how best to maintain collaboration the Conference dealt with a wide range of questions, including the application of the results of scientific research, the development of information services, the movement of scientists within the Commonwealth, the relations of the constituent organizations with international bodies concerned with science or its application and the provision of technical man-power to assist underdeveloped countries". Again, "It was agreed as particularly important that developments should be watched in the following subjects: industrial microbiology, research in . . . the utilization of low-grade ores, research on the utilization of solar energy by both physical and biological means, infertility of ruminant animals, agricultural engineering". In addition, it discussed the organization of national research bodies.

The Conference was opened by Mr. Menzies, the Prime Minister of Australia, with a most eloquent appeal that the results of scientific research should find their way as quickly as possible into the hands of those who need to have the results.

The fifth Conference was the outcome of the Commonwealth Prime Ministers' meeting in 1957. They recommended an informal meeting of Commonwealth scientists to discuss the use of nuclear energy for civil purposes. The meeting was held during September 15–20, 1958, and every Commonwealth country except Malaya was represented. Not all the delegates were nuclear scientists because the main intention of the Conference was to develop a sense of Commonwealth partnership and inter-reliance in the development and application of nuclear energy. For example, although radioisotopes are produced by nuclear science, they can be used by many other interests—medical, biological, agricultural and industrial.

In the course of their five-day meeting the Commonwealth scientists did a bit of travelling and visited Harwell, the nuclear power station building at Bradwell, Calder Hall and Dounreay. They had one non-scientific interlude when the whole party, numbering about thirty-five delegates, came to lunch with The Queen and myself at Balmoral, and I was delighted to find Dr. Nazir Ahmad and Dr. Ghani among the party.

The latest of this series of conferences was held when the British Commonwealth Scientific Committee met in Canada in August 1958. At this meeting Ghana and Malaya took their places for the first time. The meeting decided to abolish the full-scale scientific conferences and substitute regular meetings of the British Commonwealth Scientific Committee consisting of the heads of the national research organizations of the Commonwealth countries. The Committee has decided to meet again in London in 1960.

The Colombo Plan

All these conferences have given point and direction to scientific co-operation, but no discussion on this subject would be complete without a reference to the Colombo Plan, particularly the technical co-operation scheme. The Plan was the outcome of a meeting of the Commonwealth Foreign Ministers at Colombo in 1950. The main part of the Plan deals, of course, with economic matters; but under the technical co-operation scheme there is a very considerable movement of students and experts in scientific and technological subjects between Commonwealth countries as well as between other south-east Asia countries and the United States. In the past eight years nearly 7,000 trainees and students have received instruction and just over 1,000 experts have been exchanged between the nineteen countries taking part—eleven of them Commonwealth. Of these, only three have not yet received any help and only five have so far been unable to offer any help.

That, I think, is ample proof that this is a real co-operative effort.

Just as an illustration, it may interest you to know that, for example, Pakistan has received help from Australia, New Zealand, Canada and the United Kingdom, and has, in her turn, helped Burma, Japan, Malaya, the Philippines and Ceylon.

There are, of course, many schemes being developed under the Colombo Plan in Pakistan; but I am particularly interested in the Warsak hydro-electric and irrigation scheme because I hope to see how it is getting on in a few days time. It seems to be an excellent example of Commonwealth co-operation, as Canada is providing considerable technical assistance and is footing more than half the bill of 60 million dollars.

The British Association

Although, strictly speaking, the British Association is not primarily concerned with scientific co-operation within the Commonwealth, it has played quite an interesting part in the development of science and scientific institutions in Commonwealth countries. As the representative of the British Association at this meeting, I hope you will forgive me if I say a few words about its contribution. The fact is that as early as 1884 the British Association held its annual meeting for the first time out of the United Kingdom, in Montreal; in 1897 it went to Toronto, in 1905 it went to South Africa, in 1909 it was back in Canada at Winnipeg, and in 1914 it went to Australia. Since then it has been to Toronto again in 1924 and South Africa in 1929. In each case the report makes it quite clear that the personal contacts which were made at those meetings were considered highly valuable, while the suggestions made by the different sections about research projects were almost invariably put into effect. It was not a one-way business either. Visitors to the 1897 Toronto meeting were greatly impressed by the agricultural experimental stations established in Canada and it was recommended that the Council should approach the Home Government with a view to their imitation in Britain.

Modesty forbids me to suggest that any other Association for the Advancement of Science owes anything to the British Association, but they all have one pleasant feature in common. Members of any Association within the Commonwealth are welcome at any Association's meeting and every Association makes a point of inviting a delegation from other Associations to its meetings, and that is why I am here to-day.

Movement of Scientists within the Commonwealth

That, then, is a very general summary of the history and machinery of scientific co-operation within the Commonwealth; but there are, in fact, many other, perhaps more isolated, instances where the fact of the existence of the Commonwealth has affected the course of science.

Perhaps the most convincing example I can choose is the case of Lord Rutherford. Born in New Zealand in 1871, he went to Cambridge as an 1851 Exhibitioner, and from there he went to McGill University in Canada as professor of physics, where he became famous for his brilliant work on radioactivity. In 1907 he moved to Manchester, where he developed his nuclear theory of the atom and accomplished the first artificial transmutation of matter by bombardment with particles. Returning to Cambridge in 1919 as Cavendish professor, he saw his prediction of the existence of the neutron realized by Chadwick.

Two others are of particular interest. Sir Ronald Ross was born in India in 1857 and later trained as a doctor in England. Fired by the vision of Patrick Manson, he returned to India determined to find out the cause of malaria. Within three years he pinned it down to the *Anopheles* mosquito and thus paved the way for the control of one of the worst scourges of mankind.

In a different field Sir Claude Inglis is another example. Trained at Dublin, he went to Sind Irrigation in 1906, and thirteen years later he established the first large-scale hydraulic model station in the world at Poona. In 1945 he returned to England to design and direct the Hydraulics Research Station at Wallingford, and he is now engaged on the Karnafuli scheme for Pakistan.

There is, of course, an excellent example much nearer home, as the University of Lahore recently discovered when they lost Prof. A. Salam to the Imperial College of Science and Technology, London. However, the main thing is that his work on elementary particles will continue to be available to Commonwealth and world science wherever he works in the free world.

This freedom of movement, and the fact that most scientists within the Commonwealth use the same language, are conditions which we should exploit to the greatest extent for the benefit of scientists and through them of science and, ultimately, the people of the whole world.

It has long been recognized that this ability to move about freely within the Commonwealth is a unique advantage, and all the conferences of scientific co-operation have stressed the need for a greater movement of scientists between one country and another.

I was particularly interested to discover that this problem was first tackled as long ago as 1890 by the Commissioners of the Great Exhibition of 1851. In the regulations for their Science Research Scholarships it says: "The Scholarships are 'post-graduate', and are intended to enable selected students of overseas Universities who have already completed a full University course and given evidence of capacity for scientific investigation to devote themselves for two years to research work under conditions most likely to equip them for practical service in the scientific life of the Commonwealth". The Scholarships are tenable anywhere except in the country in which the student has received his scientific education. This scheme was the first of its kind and set the pattern for subsequent awards from other organizations. In 1958 the Commissioners made twenty-five awards.

I am afraid it is not a simple matter to find out exactly how many Commonwealth scientists are in fact studying or working in other Commonwealth countries under some kind of assisted exchange or scholarship scheme. The difficulty arises because the schemes are many and various and are operated by every kind of trust and benefaction.

So far as the United Kingdom is concerned, there are more than 500 schemes in operation designed to help people to study and work in that country, and some 124 to send people out of the United Kingdom. Apart from the 1851 Exhibition Scholarships, the Royal Society and the Nuffield Foundation run a bursaries scheme, and the British Council runs a universities exchange scheme.

The same sort of thing is happening outside the United Kingdom. For example, the National Research Council of Canada offers post-doctorate Fellowships, and, since 1948, some 574 research workers from other Commonwealth countries have worked in Canada, and, at the same time, about 40 Canadians each year are enabled to work in other countries. Under the Colombo Plan, Australia has taken 2,286 students from South-east Asia between 1951 and 1958 at a cost of £3 million.

Up to thirty years ago the Commonwealth and Colonial Empire looked to the United Kingdom as the scientific centre and no one spent much money on scientific research. However, in the past twenty years alone Government expenditure on research throughout the Commonwealth has risen by an estimated factor of fifteen.

Original Scientific Work in Commonwealth Countries

Statistics are well known to be misleading when handled by amateurs ; even experts can make them do strange things, and in any event numbers in science give no clue to quality. Let me just remind you of some of the original scientific work carried out in Commonwealth countries other than the United Kingdom. It is an interesting fact that no less than forty-two Nobel Awards have been won by Commonwealth scientists. But, to be more specific, in 1921 Sir Frederick Banting, working with McLeod and Best in Canada, isolated insulin. Sir Macfarlane Burnet in Australia has immensely advanced our knowledge of viruses and their diseases. South African workers have recently developed the tellurometer, which measures base lines for surveying by radar in a fraction of the time needed by conventional methods. Also in South Africa, Sir Arnold Theiler and P. J. du Toit discovered that lack of phosphorus in the soil was the cause of widespread botulism in cattle. Workers in Australia and New Zealand followed this with their discovery of the importance of trace elements in plant and animal health. Edwards in India developed a vaccine against rinderpest. Scientists in Canada have been fighting a long and unremitting battle against black rust in wheat and here in Pakistan research is active in this field as well as in mechanical rice cultivation and in cotton breeding, all of which has an international reputation. The names of Venkata Raman in physics and Ramanujan in mathematics are respected and admired throughout the world.

All this convinces me that the whole Commonwealth would benefit greatly from a larger movement of scientists either as students, research workers, scientific expedition members or as teachers. The important thing, therefore, is to devise practical and simple machinery to encourage this movement to take place.

The present pattern of scientific co-operation within the Commonwealth can be divided into five parts : (1) the regular discussion of general scientific problems and of problems particular to the Commonwealth ; (2) the discussion of the problems of the administration of science and research ; (3) the regular exchange of scientific information ; (4) the movement of scientists ; (5) technical help and advice.

(1) and (2) are achieved by regular conferences and contacts between the official research organizations. (3) is achieved by the British Commonwealth Scientific Offices and the Commonwealth Agricultural Bureaux. (4) is achieved by bursaries, scholarships, lectureships and various other schemes of assisted exchange, while the Colombo Plan has encouraged tremendous progress in (4) and (5).

I ought to add at this point that nothing I have said refers to the personal and informal contacts which exist between individual scientists within the Commonwealth. The total of this informal co-operation is probably greater than anything organized through more or less official channels, but of course there are no statistics.

Suggestions to improve Scientific Co-operation

So far I have only dealt with facts. Now I am going to be rather more rash and put forward some suggestions to increase the amount of co-operation between Commonwealth countries. I will not go so far as to say that these suggestions are possible in practice. I would merely say that they are desirable.

I would like to see the system of the Commonwealth Agricultural Bureaux extended to other sciences and set up in whichever country has the greatest interest in the particular subject. Secondly, I would like to see the system of the British Commonwealth Scientific Offices extended to other Commonwealth countries ; this may be a bit premature but, as it is, many Commonwealth countries are doing original research in subjects which are of great interest to others. Thirdly, it would make a wonderful story if countries could pool their resources and plan together the attack on common problems. I say deliberately that it would make a nice story because I do not think scientists or anyone else work that way. It always seems to me that individual laboratories like to attack problems in their own way even though they are quite willing, indeed eager, to discuss the results with anyone who is interested. Therefore, I believe the most we can hope for is a broad agreement about which problems appear to be most important for the time being, followed by a frank exchange of the results of research.

Next I would like to see joint action on scientific problems which affect Commonwealth industry, commerce and trade. Although more than half the research associations in the United Kingdom have Commonwealth members and the flow of technical information is not impeded in any way, except if the industries are in direct competition, I am convinced that wider membership of research associations and more co-operation between research associations in all the Commonwealth countries is both possible and desirable.

However, I am not blind to the complications. Scientists very naturally imagine that anything new which they discover and which seems to them important must be obviously immediately useful to industry. In fact, the most shattering scientific advances may not be of any practical use for many years while some trifling nonsense produced almost by mistake in a laboratory working on, for example, hydraulics may turn out to be vitally valuable to the boot and shoe industry. Furthermore, even if it can be proved quite easily that a particular discovery will revolutionize cotton farming, it does not necessarily follow that cotton farmers will accept and apply the discovery just like that.

For example, I understand that the Laboratories of the Pakistan Council for Industrial Research have, in fact, completed sixteen processes making use of indigenous materials which are ready for exploitation by industrialists. Some have already been taken up, but I would not be surprised to hear the chairman of that Council say that "you can lead an industrialist to the waters of science but you can't make him drink".

There is only one way to ensure the early application of scientific research. It is essential that industry and all other potential users of scientific production should be as closely associated with the research organization as possible at all times. Industries and farmers must be encouraged to make direct use of research facilities by asking questions, and they must also be made to feel a personal interest in the research activities by being asked to take part in experiments and developments.

The rules of human nature are not really very complex. If somebody offers you advice, the chances are you will tell him to mind his own business; if, on the other hand, he asks you for your advice and help, you are probably rather flattered.

The key to the problem of the application of scientific discovery is the closest collaboration between the research establishments and industry.

Benefits of Commonwealth Scientific Co-operation

So far I have assumed that there is some advantage to be gained from Commonwealth co-operation in science. I have assumed that in the long run the ordinary people of the countries of the Commonwealth will be better off if we make the fullest use of the freedom of movement of scientists and scientific ideas and a common scientific language. However, if this is true, if this business of co-operation is really and practically worth while, there must be some concrete examples which provide conclusive proof. Naturally, I would not have raised this point unless I had that proof.

I think we all agree that where it is possible scientific co-operation should be truly international, and enterprises like the International Geophysical Year, the Organization for European Economic Co-operation, and, on a smaller scale, the Commission for Technical Co-operation in Africa South of the Sahara, and the Colombo Plan show that this can happen. Nevertheless, in spite of the wide differences between the circumstances of the Commonwealth countries, the fact that they have similar institutions often makes it possible to organize co-operation on a Commonwealth scale when it is not possible internationally. For example, international efforts were made for years, without success, to organize the preparation of comprehensive catalogues of cultures of micro-organisms. Preparation of such catalogues within the Commonwealth was organized at a meeting lasting three days.

The Commonwealth operates an "Index of Translations", so that a scientific paper translated anywhere in the Commonwealth is available to any research worker. The Organization for European Economic Co-operation has so far failed in its efforts to organize a similar index.

To add weight to the argument I have chosen two examples which particularly concern Pakistan. Agriculture is, and must remain, the most important industry of Pakistan. For many years the soil will remain its main source of wealth. Anything therefore which advances the art and science of agriculture is vital.

After the First World War investigations were started by meteorologists in England to investigate the behaviour of the layer of air within 100 ft. of the ground about which practically nothing was known. The immediate purpose of this work was military—to study the rate of evaporation from the ground of poisonous gases and the travel of gas and smoke clouds. This work has been continued at Cambridge, and from measurements of the humidity and wind velocity at different heights an electronic computer can calculate the mean water-loss of crops hour by hour. It is then possible to estimate the water consumption of farm crops by physical measurements of the micro-climate. It is a bit early to say what the practical application is going to be; but it shows how scientific research planned for one object in one part of the Commonwealth can produce unexpected techniques and results for other purposes in other places. I hope this matter will be of particular interest to the president of the Pakistan Association for the Advancement of Science, whose work on soil science is well known and who now controls agricultural development in East Pakistan.

The second example concerns a specific investigation. A model investigation is now in progress at the Wallingford Hydraulics Research Station in England to determine the causes of the changes in the bed of the mouth of the Karnafuli River in East Pakistan so that the conditions at the port of Chittagong can be improved and stabilized. This particular piece of work is being done under the Colombo Plan.

In neither case has there been any question of attempting to gain either economic or political advantage. There has been no question of prestige or personal glory. These two cases are typical of hundreds which are in the pipe-lines of Commonwealth co-operation in science, pipe-lines which should be made to carry information and ideas in both directions between all members of the Commonwealth of Nations.

I do not really believe that anyone can seriously doubt that science devoted to fundamental research and the application of natural knowledge to civil and peaceful ends is capable of bestowing the most wonderful benefits upon mankind. In our own time it has brought about a period of almost headlong industrial and therefore economic expansion. I need scarcely emphasize the profound effect which science has had upon medicine and agriculture. (Although the cynic might say that science has simply made it possible for agriculture just to keep pace with the growing demand for food which is a direct result of the effects of improved medical practice.) All the same, there is no use denying that the developments brought about by scientific research have produced a whole host of new problems; problems which can only be alleviated by humane and thoughtful administration; problems which scientists, in company with all other professional groups, must face and overcome as ordinary thinking human beings.

By far the most harrowing problem is the use of science for destructive and warlike purposes. Everyone deplores it; but there is obviously no immediate solution. However, I firmly believe that if we can go on building on this foundation of peaceful co-operation between Commonwealth countries in all spheres of activity, we shall be doing much more than simply helping ourselves; we shall eventually have a structure which will give hope and confidence to all the men and nations of the world and then science at last will be freed for ever from the grim necessity to invent weapons of destruction.

RADIATION AROUND THE EARTH TO A RADIAL DISTANCE OF 107,400 KM.

By PROF. JAMES A. VAN ALLEN and LOUIS A. FRANK

State University of Iowa, Iowa City

Introduction

FOLLOWING the discovery[1-4] of the existence, in a region around the Earth, of a high intensity of corpuscular radiation temporarily trapped in the Earth's magnetic field, it became evident that observations to very great radial distances from the Earth would be desirable in determining the structure and extent of the radiation belt. A proposal[5] for such an undertaking was favourably received by the U.S. National Committee for the International Geophysical Year. Discussions soon thereafter with Drs. William H. Pickering and Eberhardt Rechtin of the Jet Propulsion Laboratory of the California Institute of Technology led to the formulation of a plan for including radiation detectors in one of the payloads of the planned deep-space probes of the U.S. Army Ballistic Missile Agency.

It was agreed that the State University of Iowa group would select, calibrate, and provide detectors and would recommend suitable dynamic ranges for the measurements as indicated by previous satellite observations; that the Jet Propulsion Laboratory would develop and build the necessary circuitry and telemetry and would do the payload engineering; and that the two groups would co-operatively test and calibrate the completed payload and reduce the flight observations. This plan was carried out.

The vehicular part of the programme was already well advanced by the U.S. Army Ballistic Missile Agency and the Jet Propulsion Laboratory (later under the general supervision of the National Aeronautics and Space Administration), and special telemetry receiving stations were being established at Mayaguez in Puerto Rico and at Goldstone Lake, California, by the Jet Propulsion Laboratory.

Radiation Detectors

Of a total payload weight of 13 lb., about 3 lb. was available for the radiation apparatus.

It was decided to use two Geiger–Müller tubes as basic detectors.

(*a*) The first was a standard, halogen-quenched Anton type 302. The regulated high-voltage supply and the scalers were similar to those previously developed at the State University of Iowa for satellite use[6]. Ingenious modifications of the circuits were made by Messrs. W. H. Victor, D. Slaughter and C. Josias of the Jet Propulsion Laboratory to provide for higher counting rates and to permit the mixed transmission on a single, continuous telemetry channel of the counting rate scaled by three different factors: 2^9 (= 512), 2^{13} (= 8,192), and 2^{17} (= 131,072). The experimental value of the dead-time τ of the system was 31·9 μsec. and the apparent counting rate r was well represented by:

$$r = R \exp(-R\tau) \qquad (1)$$

where R is the true counting rate. The apparent counting rate r was an increasing function of R up to a value of R of about 33,000 per sec., then a decreasing function of R up to a usable value of R of about 250,000 per sec., with:

$$r_{\text{max.}} = (e\tau)^{-1} = 11{,}550 \text{ per sec.} \qquad (2)$$

The absolute omnidirectional geometrical factor G_0 of the 302 Geiger–Müller tube was:

$$G_0 = 0{\cdot}75 \text{ cm.}^2 \qquad (3)$$

with an uncertainty of ± 20 per cent, at the present date of writing. The uncertainty in the final value of G_0 will be about ± 10 per cent upon completion of a variety of tests on a 'standard' comparison tube. The absolute efficiency of the tube for fast, singly charged, ionizing particles was 0·83 ± 0·05 (also being refined). Hence, if the counter is actuated only by direct penetrations of charged particles, the absolute omnidirectional intensity J_0 (flux through a sphere of 1 cm.^{2} cross-section) is given by:

$$J_0 = 1{\cdot}6\, R, \qquad (4)$$

with an absolute uncertainty of ± 20 per cent.

An extensive series of X-ray and γ-ray calibrations of the tube was also made using an integrating Victoreen r.-meter as the standard of exposure-level. Discussion of these calibrations is omitted in this preliminary report. The shielding of this counter had its minimum value of 0·67 gm./cm.^{2} (60 per cent stainless steel and 40 per cent fibre glass and 'Micarta') over a solid angle of about $4\pi/3$ steradians, an 'average' value of 1·0 gm./cm.^{2} over about 80 per cent of 4π steradians and several gm./cm.^{2} over the remaining 20 per cent. It may be noted that the 1·0 gm./cm.^{2} shielding corresponds to the range of 30 MeV. protons or to the extrapolated range of 2·2-MeV. electrons or to the absorption mean free path of 50-keV. X-rays.

(*b*) The second Geiger–Müller tube was one of a batch of tubes specially built for this experiment by the Anton Electronic Laboratories and designated Anton type 213. Its effective omnidirectional geometric factor was about 0·12 of the 302 and it was operated as a counting rate meter with the time-average anode current applied to a d.c. amplifier designed at the Jet Propulsion Laboratory. No in-flight calibration was provided, but special care was

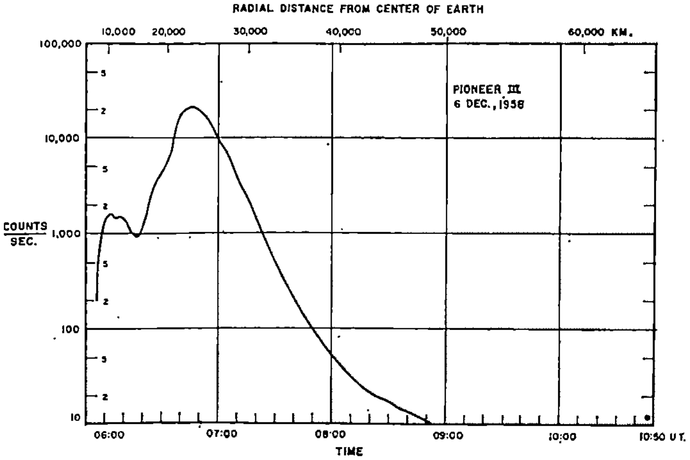

Fig. 1. Semi-log plot of true counting rate R of the 302 Geiger–Müller tube versus time of observation on the out-bound leg of the flight of *Pioneer III*. Radial distance from the centre of the Earth is shown at the top of the figure. The geographical longitude during the period shown was 30° W. at 0600; 0° at 0630; 5° E. at 0700; 4·6° E. at 0730; 2° E. at 0800; 2° W. at 0830. The curve is based on 93 plotted points. Absolute accuracy of individual points is ± 3 per cent from 0556 to 0630; ± 10 per cent from 0630 to 0720; ± 3 per cent from 0720 to 0800 and ± 2 per cent from 0800 to 0850. The lesser absolute accuracy at the higher counting rates is due to inaccuracy of equation (1) of the text

taken in reducing the dependence of the telemetered output upon supply voltages and environmental conditions. The output was a monotonically increasing function of the radiation-level to which the counter was exposed, being linear for low levels and approaching an asymptotic, saturated value for very high levels. Thus, this detector served as a crude radiation-survey device in its own right. More important, its operating characteristics were adjusted so that it served as an 'ambiguity resolver' for the 302, that is, its output was used to decide on which branch of the characteristic curve (cf. equations 1 and 2) of the 302 the latter tube was operating at any instant. This property of the 213 system was an essential one in interpreting the flight observations (see below). The shielding of the 213 tube was nearly identical to that of the 302.

Transmission of Data

All aspects of the radio-telemetry system were handled by the Jet Propulsion Laboratory. A new transmitter, radiating about 150 mW. at 960·05 Mc./sec., was developed and used for the first time. The transmitter was phase modulated by the summed output of three audio-frequency subcarrier oscillators. Channel 1 (centre frequency 400 cycles/sec.) transmitted payload temperature and several other functions. Channel 2 (centre frequency 560 cycles/sec.) transmitted the quasi-d.c. output of the 213 Geiger–Müller tube. Channel 3 (centre frequency 730 cycles/sec.) changed frequency discontinuously (with an effective time constant of 10 sec.) among eight different states corresponding to the output of the composite scaling circuit connected to the 302 Geiger–Müller tube.

The two primary receiving stations were established by the Jet Propulsion Laboratory for the Army probe firings: one near Mayaguez, Puerto Rico, with a 10-ft. dish and one at Goldstone Lake, California, with an 86-ft. dish. Auxiliary receiving stations were located near the launching site at Cape Canaveral, Florida.

Vehicle and Trajectory

The overall vehicular engineering of *Pioneer III* was done jointly by the U.S. Army Ballistic Missile Agency, under the technical direction of Dr. Wernher von Braun and by the Jet Propulsion Laboratory. The first stage was a modified *Jupiter*. The second, third and fourth ('high speed') stages were solid-fuelled Jet Propulsion Laboratory rockets.

The actual flight trajectory was determined by the Jet Propulsion Laboratory by a complex 'best fitting' technique to directional and Doppler-frequency observations from the several receiving stations. The trajectory which has been used in preparing the present article is a preliminary one, the accuracy of which during the re-entry phase is estimated to be of the order of 1,000 km. The outgoing portion of the trajectory is known to an accuracy of ± 100 km. to radial distances of the order of several thousand kilometres. A cumulative deterioration of accuracy occurs thereafter. Recalculation of the 'final' trajectory is still in process. The spatial plots of radiation intensity will be appropriately adjusted in a later article.

In addition, the preliminary trajectory has been converted to eccentric geomagnetic co-ordinates through the courtesy of Dr. Charles Lundquist of the U.S. Army Ballistic Missile Agency.

Log of Flight and Telemetry (*Pioneer III*)

(*a*) *Log of flight.* Launch from Cape Canaveral, Florida, at 0545 U.T., December 6, 1958. (28·5° N., 80·8° W.) Burn-out velocity (space fixed): 10·68 km./sec. Apogee: 108,700 km. radial distance from centre of Earth, geographic latitude 23·74° S., geographic longitude 145·5° E. at 0049 U.T., December 7.

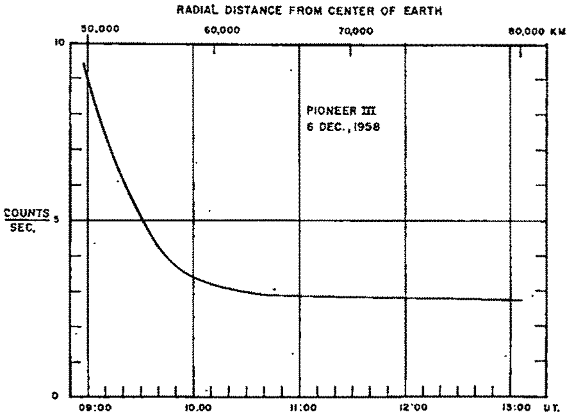

Fig. 2. Linear plot of true counting rate R of the 302 Geiger–Müller tube versus time of observation on the out-bound leg of the flight of *Pioneer III*. The geographical longitude during the period shown was 7° W. at 0900; 17° W. at 1000; 29° W. at 1100; 42° W. at 1200; and 54° W. at 1300. The plot is based on 38 plotted points of ± 4 per cent accuracy each

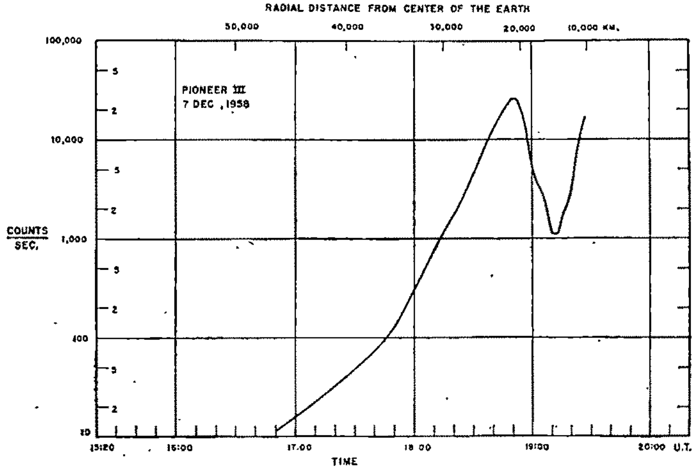

Fig. 3. Semi-log plot of true counting rate *R* of the 302 Geiger–Müller tube versus time of observation on the in-bound leg of the flight of *Pioneer III*. The geographical longitude during the period shown was 61° W. at 1700; 65° W. at 1800; 64° W. at 1830; 56° W. at 1900; 25° W. at 1930; and 0° at 1936. The curve is based on 48 plotted points with accuracy of each point ± 2 per cent from 1650 to 1820 and no greater than ± 10 per cent thereafter

Extrapolated impact with the Earth: geographic latitude 16·18° N., geographic longitude 20·30° E. at 1943 U.T., December 7.

(*b*) *Log of telemetry.* December 6: 0549–1410 U.T. Puerto Rico—solid telemetry; 1330–2213 U.T. Goldstone Lake—solid telemetry. December 7: 1154–1425 U.T. Puerto Rico—radio-frequency received but signal too weak for readable telemetry; 1425–1520 U.T. Puerto Rico—telemetry intermittently readable; 1520–1930 U.T. Puerto Rico—solid telemetry.

Radiation Observations

Due to excellent telemetry (see previous section), continuous radiation observations were obtained on the out-bound leg of the trajectory to a radial distance from the centre of the Earth of 107,400 km. (nearly to apogee) and from 60,000 km. to 9,400 km. on the in-bound leg.

The true counting rate of the 302 tube is plotted and presented in Figs. 1, 2 and 3. The output of the 213 tube, not shown in detail in the present article, was consistent with that of the 302 tube throughout and in addition served the important function of ambiguity-resolver, mentioned above, in assuring that there are indeed two distinct peaks of intensity separated by relative minima as shown in Figs. 1 and 3.

Fig. 4 gives a schematic view of the observations with selected values of the true counting rate of the 302 Geiger–Müller tube marked on a meridian plane-polar co-ordinate plot of the trajectory.

Intensity-Structure of the Region of Trapped Radiation

There are two distinct, widely separated zones of high intensity. In our previous work[7,8] with satellite 1958ε it was found that contours of constant counting rate of a Geiger–Müller tube very similar to the 302 tube of *Pioneer III*, though somewhat more heavily shielded, suggested a dough-nut-shaped region centred on the geomagnetic equator as being the region of maximum intensity. In addition, the contours showed tongue-like regions of radiation extending downward toward the Earth at high geomagnetic latitude, both north and south. The high-latitude edges of these tongues were near the low-latitude edges of the usual auroral zones, a suggestive fact which has been discussed[7,8]. In Fig. 8 of ref. 7 a speculative extension of the contours observed with satellite 1958ε was presented. The diagram given therein was one of two types which we had sketched as plausible extensions of the observed contours. The other one of the two, particularly advocated by C. E. McIlwain of this laboratory, regarded the high-latitude, tongue-like contours as the tips of an outer, banana-shaped region (in meridian cross-section). This view implied a second maximum in intensity as one passes outwards from the Earth in the plane of the geomagnetic equator. The new *Pioneer III* observations show that this second diagram was indeed more nearly true than the one previously published. Our revised and present best picture of the situation is given in Fig. 5. This diagram harmonizes in a single representation our very extensive observations with satellite 1958ε (up to altitudes of 2,200 km.) and the new observations with *Pioneer III*. The latter were the 'one-dimensional' observations along the curved trajectory lines shown in Fig. 5.

The heavy black dots on these lines show specific points through which the contours were

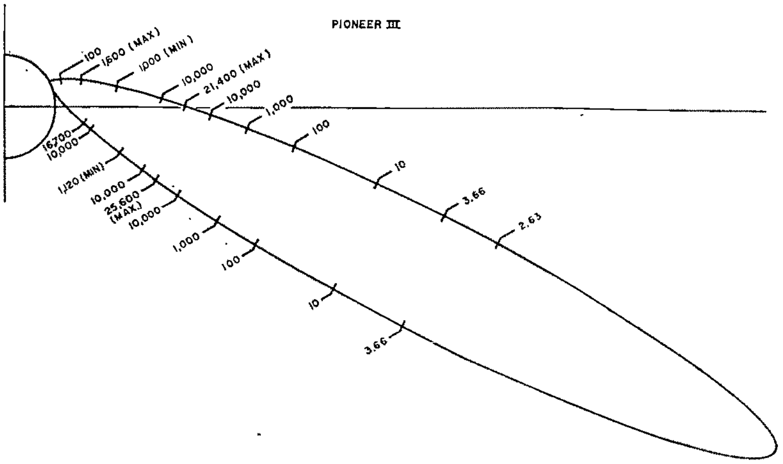

Fig. 4. A geographical plot, to scale, of the projection on a (rotating) meridian plane of the trajectory of *Pioneer III*. The semicircle at the left represents the cross-section of the solid Earth. Polar co-ordinates are radial distance from the centre of the Earth and the geographical latitude. The vertical axis is the geographical axis of the Earth with the north end up. The numbers are true counting rates *R* at selected positions along the trajectory. The out-bound leg of the trajectory is the upper portion of the curved line

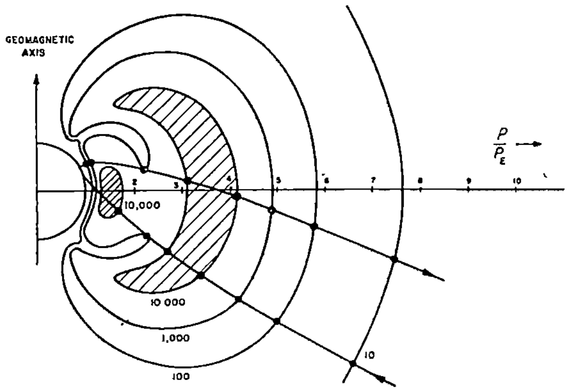

Fig. 5. A plot in a geomagnetic meridian plane of the intensity-structure of the radiation region around the Earth. The numbers associated with the several contours of constant intensity are the true counting rates R of the Geiger–Müller tube in *Pioneer III* or in satellite 1958ε. Within the two cross-hatched areas R exceeds 10,000/sec. See text for further discussion

drawn. Much of the diagram remains conjectural, of course.

The complete intensity-structure of the trapped radiation regions may be more complex than that shown in Fig. 5; but we believe that it cannot be essentially simpler. Inasmuch as the features of the diagram due to 1958ε observations persisted through a two-month period during July–August–September 1958, we regard the outer zone as well as the inner one as a quasi-permanent feature, although the *Pioneer III* observations would not in themselves permit such a conclusion, since they were made within a single two-day period. With detectors of lesser or greater stopping power, the structure of the radiation zones may be found to be different; but results with the diversity of detectors in satellite 1958ε suggest that it will be similar for a wide range of stopping powers.

It now appears that the outer zone is the one more intimately related to usual, high-latitude auroræ.

It will not, of course, be surprising if the level of intensity of trapped radiation and indeed the structure of the entire radiation region are found to be strongly dependent on solar activity, averaged over an appropriate mean trapping time (for example, several weeks or months). In our present view, gross fluctuations on an eleven-year cycle would be expected. Details of the intensity-structure may fluctuate, of course, on a much shorter time scale.

The *Pioneer III* observations give no information on the range spectrum of the trapped radiation. But as previously reported[7,8], the 1958ε observations show that the radiation at high altitudes near the geomagnetic equator is more penetrating than that in high latitudes. This fact together with Fig. 5 encourages one to conjecture that the inner and outer zones may have different physical origins; for example, the outer one due to solar plasma and the inner one due to cosmic ray albedo decay products. Another possibility may be selective radial diffusion of particles in the inhomogeneous geomagnetic field according to their respective magnetic rigidities[9] or according to a combination of the sign of their electrical charge and their magnetic rigidity.

It is obviously of great importance to learn the respective energy spectra of protons and of electrons throughout the trapping region. In the light of the above conjectures, special interest is attached to learning the spectral differences, if any, between the radiation in the inner zone and that in the outer zone.

A satellite in a pole-to-pole orbit of high eccentricity is desirable in order to plot the structure of the radiation region to a good level of satisfaction and to follow its temporal changes. Another attack on the matter can be visualized by using a 'vertical' probe (ideally in the plane of the geomagnetic equator) equipped to measure at each point along its trajectory the angular distribution and energy spectra of electrons and protons separately. Such information is adequate in principle to plot the entire region if one makes full use of the theory of the motion of charged particles in the (approximately known) geomagnetic field.

Effective Radial Extent of the Geomagnetic Field

In the range $27{,}000 \lesssim \rho \lesssim 37{,}000$ km., where ρ denotes the radial distance from the centre of the Earth, the counting rate R is accurately represented by an equation of the form:

$$R \sim \exp(-\rho/2300) \qquad (5)$$

Beyond 37,000 km. the counting rate continues to decline smoothly though progressively less rapidly with increasing ρ. Beyond some 64,000 km. ($\rho = 10$ times the radius of the Earth, ρ_E) the rate of decline becomes very much less (Fig. 2).

Although there is nowhere an abrupt cut-off, it appears reasonable, from Fig. 2, to consider the outer limit of the region of trapped radiation to be at $\rho/\rho_E = 10$. At this radial distance the intensity of the trapped radiation, at least as measured with the present equipment, becomes less than the interplanetary cosmic-ray intensity (see the following section). The following quantities are pertinent to a discussion of the significance of this result:

At $\rho/\rho_E = 10$, (*a*) the strength of the idealized dipole field of the Earth is $B = 3{\cdot}1 \times 10^{-4}$ gauss; (*b*) the corresponding magnetic energy density is $B^2/8\pi = 3{\cdot}8 \times 10^{-9}$ ergs/cm.^{3}; (*c*) the maximum magnetic rigidity which a charged particle can have and still be trapped in an idealized dipole field if it is moving in the least favourable trajectory is $pc/ze = 1 \times 10^8$ V. (Störmer cut-off). This magnetic rigidity characterizes a proton of 5×10^6 eV. kinetic energy or an electron of 100×10^6 eV.

It may also be noted that: (*a*) the shielding of our Geiger–Müller tube is such as to stop 30×10^6 eV. protons or $2{\cdot}2 \times 10^6$ eV. electrons; (*b*) the Störmer cut-off at $\rho/\rho_E = 6$ corresponds to the proton energy just sufficient to penetrate the shielding of the Geiger–Müller tube.

Consideration of the observed results in conjunction with these facts leads us to conclude that probably neither of the two straightforward criteria for loss of trapping effectiveness, that is, the Störmer criterion, or the volume density of particle kinetic energy being comparable to the magnetic energy density, is the dominant one.

Disturbance of the idealized dipole field of the Earth is progressively easier at greater radial distance. It is commonly supposed that the effective radial extent of the geomagnetic field is determined by the prevailing interplanetary field. In the circumstances of the flight of *Pioneer III* it appears that the interplanetary field may have been as great as 3×10^{-4} gauss, though perhaps a field weaker by an order of magnitude would suffice.

A more quantitative view of the steady decline of the trapped intensity beyond $\rho/\rho_E \sim 3\cdot5$ may indicate that the loss of trapped particles is progressively more probable with greater distance due to intermittent perturbations (from solar gas) the effect of which is, on the average, greater at greater radial distances.

It is of interest and perhaps of significance to note that a dipole line of force through $\rho/\rho_E = 4\cdot8$ on the geomagnetic equator reaches the Earth's surface at a geomagnetic latitude of 63°, the approximate lower latitude boundary of the usual zone of maximum auroral activity; and one through $\rho/\rho_E = 10$, at 71·5°, the approximate higher latitude boundary.

Interplanetary Value of Cosmic Ray Intensity

Beyond 10 Earth radii, the counting rate of the 302 declines very gradually and appears to have reached an asymptotic value of 2·25 counts/sec. at the outermost point of the observations, namely, 17 Earth radii. It is not known whether or not there remains a significant contribution from a residuum of geomagnetically trapped radiation or from soft, interplanetary radiations. On the basis of the observed radial dependence of counting rate it is quite likely that the residuum of trapped radiation contributes negligibly at $\rho/\rho_E = 17$.

The Earth's dense atmospheric shell subtends a solid angle of 10^{-3} of a sphere at the position of the apparatus at $\rho/\rho_E = 17$. Hence the Earth is a negligible source of high-energy escaping albedo and is also a negligible scattering and absorbing body for high-energy primary cosmic rays.

The idealized Störmer cut-off at this radius is $0\cdot03 \times 10^9$ V. magnetic rigidity, corresponding to kinetic energies of 5×10^5 eV. for protons or 3×10^7 eV. for electrons.

Thus, subject to the above discussion, we find:

$$J_0(\text{interplanetary}) = 3\cdot6 \pm 0\cdot8 \ (\text{cm.}^2/\text{sec.})^{-1} \qquad (6)$$

Almost the entire uncertainty in this preliminary result is due to the uncertainty in the absolute geometrical factor (see section on transmission of data). No previous measurement of J_0 at a point remote from the Earth has been made. The significance of this result will be discussed in a later article.

Fluctuations in Counting Rate Beyond 10 Earth Radii

The counting rate of the 302 tube did not fluctuate beyond statistical expectations during the some 12 hr. of observations at radial distances greater than 10 Earth radii: and in fact, its rate at lesser distances was a remarkably smooth function of time (or of spatial position). This appears to mean either that no 'blobs' of interplanetary plasma were encountered during this observing period or that any such blobs did not contain sufficiently energetic radiation to produce a significant contribution to the counting rate. No critical assessment of the prevailing solar-terrestrial situation has been made as yet. The preliminary Climax report indicates mild to moderate solar activity.

Biological Exposure-Levels

If there is an omnidirectional intensity J_0 of charged particles at a point, then the rate of ionization produced in a test quantity of air there may be measured in roentgens per hour. The equivalence is:

$$(\text{roentgens/hr.}) = 1\cdot25 \times 10^{-4}\,\overline{(S/S_m)}J_0 \qquad (7)$$

where J_0 is in particles/cm.² sec. and $\overline{(S/S_m)}$ is the mean ratio of specific ionization of the particles to the minimum value for a fast, singly charged particle (1·8 MeV./(gm./cm.²)). The omnidirectional intensity measured by *Pioneer III*, if attributed to charged particles only, is given by:

$$J_0 = \frac{R}{(0\cdot75)(0\cdot83)} = 1\cdot6\,R \qquad (8)$$

where R in sec.$^{-1}$ is the true counting rate as plotted in Figs. 1, 2, 3, 4 and 5.

For practical use of Figs. 1, 2, 3, 4 and 5, one may combine equations (7) and (8) to give:

$$(\text{roentgens/hr.}) = 2\cdot0 \times 10^{-4}\,\overline{(S/S_m)}R \qquad (9)$$

For example, the maximum observed exposure-levels in the hearts of the two radiation zones are in the range 5–10 roentgens/hr. if the response of the detector is due only to direct penetrations by electrons. If its response is due only to protons having a rapidly falling spectrum in the tens of MeV. range, as another example, $\overline{(S/S_m)}$ is of the order of 10–20 and the exposure would be in the range of 50–100 roentgens/hr.

It is, of course, understood that these estimates are valid only for the shielding actually used in this experiment (see section on radiation detectors). It is still not known how absorbable the radiation is at various points in space.

Discussion of exposure-levels if the response of the detector is due only to bremsstrahlung from electrons (of energy less than 2·2 MeV.) stopped in the apparatus will be given in a later report.

In addition to the acknowledgments in the body of this article, we should like to mention the many fruitful conversations with Dr. Ernest C. Ray and with Messrs. Carl E. McIlwain and George H. Ludwig of this laboratory.

The engineering of the payload of *Pioneer III* was supervised by Mr. Dan Schneiderman of the Jet Propulsion Laboratory. Support for the State University of Iowa portion of the experimental work and the analysis of observations was provided in part by a sub-contract with the Jet Propulsion Laboratory.

NEWS and VIEWS

Prof. C. T. R. Wilson, C.H., F.R.S.

C. T. R. Wilson celebrates his ninetieth birthday on February 14 at his home in Carlops, close to his place of birth, the farmhouse of Crosshouse in the Pentland Hills near Edinburgh. It is now almost half a century since he exposed the air in his cloud chamber to X-rays "with little expectation of success, and in making an expansion of the proper magnitude for condensation on the ions while the air was exposed to the rays, I was delighted to see the cloud chamber filled with little wisps and threads of clouds—the tracks of electrons, ejected by the action of the rays". Here was the instrument which, suitably developed and adapted, was to provide photographs giving an almost complete record of the development of nuclear physics during the succeeding thirty years. The disintegration of nitrogen by alpha-particles was first photographed by Blackett in 1925, and the first example of disintegration produced by neutrons was similarly obtained by Feather in 1932. The power of the Wilson method was greatly extended and its application to cosmic-ray studies facilitated when Blackett devised the automatic control of the chamber by the rays. First evidence for the positron had been discovered by Anderson in 1932, using the method of random expansions; Blackett and Occhialini, using the counter-controlled chamber in the following year, were quickly able to obtain massive support for Anderson's discovery. In 1937 Anderson and Neddermeyer obtained evidence for mesons in cosmic rays from cloud-chamber photographs. While the simpler technique of using fine-grain photographic emulsions for recording nuclear reactions has superseded the cloud chamber, especially in the investigation of the tracks of heavy particles, there are many reactions requiring controlled observation which can be studied only by the Wilson method.

The world-wide recognition that the association of his name with the cloud chamber has brought to 'C. T. R.' has tended to obscure the fact that his investigations of atmospheric electricity and of the electric fields of thunderstorms have provided the basis of our knowledge in this field. Only a year or two ago, he published a paper on the mechanism of the generation of electric charge in thunderclouds in the *Proceedings of the Royal Society*, of which he is senior Fellow. It is perhaps not generally known that the whole of Wilson's scientific work developed out of certain experiences on Ben Nevis—the cloud chamber from his observations in 1894 of glories seen from the edge of the summit precipice overlooking the great corrie, and the thunderstorm work from feeling the effects of sudden changes in the electric field of a thundercloud while standing on the summit of Carn Mor Dearg in 1895. 'C. T. R.' still retains his interest in clouds, and takes every opportunity of flying into them by joining members of the class of meteorology at the University of Edinburgh in flights arranged for them by the Royal Air Force. Some of his colleagues from Sidney Sussex College and former students at Cambridge are to lunch with the Wilson family in the Allan Ramsay Inn at Carlops on Tuesday, February 17.

Rumford Premium of the American Academy of Arts and Sciences: Prof. G. Wald

The Rumford Premium for 1959 of the American Academy of Arts and Sciences has been awarded to Prof. George Wald, of Harvard University, for his work on the biochemical basis of vision. In addition to the traditional gold and silver medals, this award, established by the Academy 163 years ago, carries a premium of 5,000 dollars to the recipient. The formal presentation will be made at a meeting of the Academy on March 11, 1959. Prof, Wald was born in New York City in 1906. He graduated in New York University in 1927 and was awarded his doctorate by Columbia University in 1932. As a graduate student, he came under the influence of Prof. Selig Hecht, who played an important part in Dr. Wald's subsequent career. During 1932–34 he was a National Research Council Fellow in Berlin, Heidelberg, Zurich and Chicago. He went to Harvard as a tutor in biochemical sciences in 1934 and became professor of biology in 1948. His research has centred on the chemistry of the visual process, with particular reference to the chemical changes which occur in the rods and cones of the eye following excitation by light quanta. Recent work from his laboratory in this field is described in this issue of *Nature*, p. 442.

Royal Society Committee on Scientific Research in Schools

In order to assist schoolteachers who wish to pursue scientific research the Royal Society established a Committtee on Scientific Research in Schools in March 1957. The following were appointed members: for the Royal Society, Sir Lindor Brown (chairman), Dr. F. P. Bowden, Sir Edward Salisbury; for the Science Masters' Association: Mr. W. Ashhurst, Mr. R. H. Dyball, Mr. M. C. Nokes. Later Dr. C. G. Williams was appointed as an additional member. Dr. Williams is director and general manager of Shell Research, Ltd.; the Committee has been greatly encouraged and assisted by this company, which in 1956 took up this question and is at present supporting research work in nine schools. A statement about the Committee and its aims was circulated to the headmasters and headmistresses of 1,383 schools in the British Isles at the end of 1957. Requests for advice have been received from fifty-seven schoolmasters and mistresses, and twelve research projects are at present being undertaken with the assistance of the Committee, in addition to those previously initiated by Shell Research, Ltd. Twenty-one additional research projects are at present under consideration. The Science Museum Library has agreed to lend periodicals to those carrying out work under the advice of the Committee. Considerable assistance in making literature available has also been given by various university departments and a scheme is being operated by the Royal Institution whereby its library may be used by schoolmasters and mistresses for a small subscription. All research projects with which the Committee is dealing have been scrutinized by Fellows of the Royal Society or by others who have agreed to act as advisers. In a number of cases, Fellows have lent apparatus from their own departments for particular projects. The response to this scheme has been very encouraging and consideration is now being given to placing under the ægis of the Committee the research projects at present assisted by Shell Research, Ltd. The Committee looks forward both to receiving further requests from schools and to the continued valuable support of Fellows of the Royal Society and others in acting as advisers and assisting in the extension of its activities.

Nuclear Reactors on a Commercial Basis

IN reply to a question in the House of Commons on February 5, the Prime Minister stated that the United Kingdom Euratom Agreement was signed on February 4 and the text was published as a White Paper. The prospects for sales of British reactors in the Euratom market, he said, will depend on commercial considerations; but the established achievements of the Calder Hall prototypes and the developments incorporated in the later commercial designs now available for export should give British manufacturers a good prospect of success in Euratom countries. Mr. Macmillan agreed that the ability of the United States to supply fuel for the first year free of charge made it difficult to compete in contracts for power stations, although he believes that Britain is further advanced in this field than the United States are. It is, however, an expanding field and besides the Euratom Agreement Britain has already made separate agreements with individual countries, and this has resulted in an arrangement for a British plant to be erected in Italy.

Fog Dispersal

THE Parliamentary Secretary to the Ministry of Transport and Civil Aviation stated in reply to a question in the House of Commons on February 4 that research carried out by the Ministry of Supply indicates that the most promising method of fog dispersal is the thermal one known as F.I.D.O. His Ministry is collaborating with the Ministry of Supply in tests with a new type of F.I.D.O. installed at an R.A.F. aerodrome. This is a high-pressure system with a new type of burner which, it is hoped, will be more economical in operation. The old system was very expensive both to install and to operate. Although F.I.D.O. could provide a clear area, there would still remain the problem of the wall of fog which the aircraft would have to penetrate first. It is considered unlikely that automatic landing equipment would provide a complete solution to the problem.

Electrical Instrument Test Service

THE British Scientific Instrument Research Association has established an electrical instrument test service at its laboratories in Chislehurst, Kent. Although originally set up at the request of members of the Association, the service is now available to other firms and organizations. It is operated under the supervision of the National Physical Laboratory and will test and issue certificates for instruments up to 'Precision Grade' accuracy. Calibration of d.c. meters between 1 mV. and 500 V. and between 2 μamp. and 2 amp. can be undertaken immediately. In the near future the latter range is to be extended to 25 amp., and the calibration of a.c. instruments over the ranges 1–500 V. and 10 m.amp.–25 amp. will be undertaken. Charges for the service will be appreciably less than the cost of National Physical Laboratory certification. Further information can be obtained from the Director of Research, British Scientific Instrument Research Association, South Hill, Chislehurst, Kent.

Bird Migration

IN addition to its established quarterly journal, *Bird Study*, the British Trust for Ornithology has launched a half-yearly publication entitled *Bird Migration* (1, No. 1; December 1958. iv+40 pp. 2*s*. 6*d*.). This is related to the Trust's recently adopted scheme for co-ordinating the activities of the score of bird observatories which now form a remarkable network around the British coasts, and for ensuring the complete availability and summary publication of the data collected. A grant made for five years by the Nuffield Foundation has enabled the Trust to appoint a whole-time migration research officer, Mr. Kenneth Williamson, who edits the new journal. This first issue includes a series of summary reports from the individual observatories on the autumn migration of 1958, followed by an editorial review of the more notable aspects of the movements as a whole. The season is shown to have been an interesting one in several respects, and this convenient account of it—accompanied by weather maps where necessary—is welcome. The value over a sequence of years should be cumulative.

Plastics Abstracts

PLASTICS INVESTIGATIONS is publishing a new weekly journal, *Plastics Abstracts*, which aims to give a comprehensive abstracting service covering British patent specifications and periodical articles dealing with the science, technology and applications of plastics. A valuable feature of these abstracts is the promptness with which they are published—normally one week after publication of the original patent specifications, and within two weeks of publication of the periodical articles. The preparation of this journal is based on a complete weekly scrutiny of British patent specifications and the regular examination of about 250 periodicals. Detailed author, patent and subject indexes will be published annually, and subscribers' requests for specific information contained in the current year's abstracts will be answered free of charge. *Plastics Abstracts* is obtainable from the publishers, Plastics Investigations, 23 Canonsfield Road, Welwyn, Hertfordshire. The subscription rates are £25 annually including postage, or £35 by air-mail; single copies can be obtained for 10*s*., or 14*s*. by air-mail.

Drilling a Borehole to the Earth's Mantle

PROF. HANS PETTERSSON has recently written an article in the *Stockholms-Tidningen* about drilling a deep hole to the Mohorovičić discontinuity between the Earth's mantle and the surface rocks, in which he refers to the article by Dr. T. F. Gaskell in *Nature* of September 13, p. 692, which discussed this project. Prof. Pettersson reminds his readers that the only knowledge of the depth of the base of the Earth's crustal rocks is that obtained from the study of earthquakes. These observations, however, do not allow one to say with certainty what is the rock material which constitutes the Earth's mantle. It is possible that some of the research concerned with the planets and the Moon may give useful clues to what material exists inside the Earth, but there is a strong argument for spending part of the limited amount of money available for research on the more direct approach of drilling down into the Earth. As Dr. Gaskell pointed out, it is only the cost of drilling to the Mohorovičić discontinuity that is holding the project back: it would be possible from a technical point of view to start to-day. This is especially true of the proposal to drill through the sediments that cover the floor of the deep oceans.

Prof. Pettersson is, of course, one of the world's experts in the deep-sea sediments, but even with his best corers he has managed to penetrate only the top 20 m. of the sea-bed. He points out how important the complete column of deep-ocean sediments will be, because they must surely contain the history of the past geological behaviour of the Earth. Prof. Pettersson does not mention the United States Navy research project which has been set up to look into the economics and desirability of the Mohorovičić and deep-ocean sediments projects which were suggested at the Toronto International Geophysical Meeting in 1957, nor does he say anything about the rumoured Russian attempts to be first in this field.

Regional Museum Council

For many years the Museums Association has endeavoured to obtain some form of assistance from the Government for the smaller museums in Britain. It is well known that in several instances the position is desperate, and valuable material is being lost for want of proper conservation. During the past eighteen months a committee of inquiry in the south-west of England has accumulated facts, and at a meeting at Taunton on January 8 presented a report on the present position of museums in its area together with a series of maps indicating the distribution and size of the collections in the fields of archæology, applied art, fine art, botany, folk-lore, furniture, geology, numismatics and zoology. Dr. W. E. Swinton, president of the Museums Association, was in the chair for this, what may well prove to be a historic, occasion.

After full consideration of the report, it was decided to form a Regional Museum Council. The scope of this Council will include the counties of Bristol, Cornwall, Devon, Dorset, Gloucestershire, Somerset and Wiltshire and the town of Newport in Monmouthshire, while its objects will be to promote co-operation, improve technical facilities and to grant financial assistance to museums and art galleries within the region. The Council will consist of twenty-two members, and it has power to co-opt and make provision for alternate members. Sir John Hobhouse has been appointed chairman and Mr. F. J. Stott vice-chairman of the Council. The outcome of this initial effort on the part of the museums of the south-west of England will be awaited with interest, for if successful it will probably be followed by other regional councils in various parts of the British Isles.

United States Atomic Energy Commission Training Courses

The U.S. Atomic Energy Commission has made grants totalling 2,264,965 dollars to forty-one universities and colleges in the United States for the purchase of laboratory equipment needed to expand their nuclear educational programmes. These grants include funds to seven engineering institutions, namely, Kansas State College and the Universities of Illinois, Maryland, Texas, Washington, West Virginia and Wisconsin, for the purchase of teaching reactors. The seven reactor grants bring to thirty the total number of teaching reactors in operation or to be constructed in American universities with the help of Commission grants.

The U.S. Atomic Energy Commission has also started a new programme of assistance to colleges and universities in the United States for education and training in radioisotope principles and technology. Direct financial assistance is to be given in obtaining demonstration apparatus, student laboratory equipment and training aids needed to offer adequate laboratory course-work in radioisotope technology.

Pyrite Granules and Fossil Micro-organisms

Small spheres, usually less than 50μ across, composed of tightly packed pyrite crystals, are common in sedimentary rocks. They have been noted in rocks of both marine and freshwater origin, from those of the Cambrian to present-day sediments, and have previously usually been considered to be of inorganic origin or to have been associated with the activities of sulphur bacteria. L. G. Lowe has recently shown that spheres of this kind from certain beds of the Scottish Lower Carboniferous oil shale group enclose microfossils of a hitherto unknown group (*Quart. J. Geol. Soc.*, 113, 429; 1958). The two new monotypic genera, *Pyritosphaera* and *Pyritella*, are both rounded in form and apparently multicellular, the surface of the former being covered with radial spines. The affinities of these genera cannot at present be defined, but they are evidently not bacteria. It is suggested that during their life-time the organisms generated hydrogen sulphide as a by-product of the anaerobic decomposition of sulphur compounds (probably sulphates) and that the gas reacted with iron ions to precipitate iron sulphide on their surfaces. It remains to be seen whether future studies will reveal a range of genera and species capable of being used as stratigraphic or environmental indices, as has been the case with so many other types of microfossils in recent years, but it seems clear that where found *Pyritosphaera* and *Pyritella* demonstrate stagnant conditions at the time the containing sediment was formed.

Morhana Parar

The issue of *Man* of last October contains an interesting article by Dr. Allchin which deals with a number of deep rock shelters in India, called Morhana Parar, which have yielded numerous pigmy tools, and the walls and ceilings of which have been painted. The sites, near the village of Bhainswar, some 42 miles south of Mirzapur on the Great Deccan Road, had been investigated as long ago as 1880 by A. C. Carlleyle, who died before he had been able to deal with his discoveries, and the caves had been forgotten. Some of the 'loot', however, seems to have found its way into several European museums and collections. Now the sites have been rediscovered and studied by Dr. Allchin. The paintings consist of hunting and dancing scenes, chariots and animals. It is to be presumed that the makers of the pigmy tools were the painters.

Disposal of Radioactive Waste

A detailed study of the microbiology and water circulation in the Black Sea by A. E. Kriss (*Priroda*, 6, 43; 1958) and the water circulation in oceans by V. G. Bogorov and E. M. Kreps (*Priroda*, 9, 45; 1958) show that the vertical circulation of sea and ocean waters would not allow the disposal of radioactive waste in their deeper zones (see *Nature*, 182, 563 ; 1958).

D.S.I.R. : Longer-term Grants for Special Researches

LONGER-TERM grants for special researches will be awarded by the Department of Scientific and Industrial Research in future. These grants—which have normally been limited to a maximum of five years—may now be awarded for an initial period of up to seven years with the possibility of continuing support for a further ten years. When fully established, the support for these researches will be transferred from the Department to a university. The Department is therefore willing to support for longer periods outstanding university investigators embarking on promising researches for which their universities are unable to make adequate provision. The first closing-date for applications is March 1. Further information can be obtained from the Department of Scientific and Industrial Research, 5–11 Regent Street, London, S.W.1.

University News : Birmingham

THE following appointments have been announced in the University of Birmingham: G. S. Pittaway to be lecturer in chemical engineering ; Dr. W. T. Roberts to be lecturer in industrial metallurgy ; Dr. A. L. Haigh to be lecturer in physiology.

Durham

PROF. E. LEDERER of the Institut de Biologie Physico-Chimique, 13 Rue Pierre Curie, Paris, will visit King's College in the University of Durham, Newcastle upon Tyne, during March 3–21 and for a further period after Easter.

University College of Rhodesia and Nyasaland

MR. D. J. EVE has been appointed lecturer in inorganic and physical chemistry.

Announcements

PROF. N. F. MOTT, Cavendish professor of experimental physics in the University of Cambridge, has been elected Master of Gonville and Caius College, Cambridge, in succession to Sir James Chadwick, who is retiring.

MR. W. S. ELLIOTT has been appointed managing director of IBM World Trade Laboratories (Great Britain), Ltd., a new subsidiary of IBM World Trade Laboratories Corporation of New York. At present the Laboratories are at Hursley House, near Winchester in Hampshire, but it is planned to erect a new laboratory in the Southampton area. Research and development are being undertaken in the field of electronic data processing and computing.

A RESIDENTIAL working conference on Automatic Programming of Digital Computers will be held in the Department of Mathematics, Brighton Technical College, during April 1–3, under the direction of Dr. A. D. Booth. Further particulars and forms of application can be obtained from the Registrar, Brighton Technical College, Richmond Terrace, Brighton.

THE Stress Analysis Group of the Institute of Physics, in collaboration with the Instituut T.N.O., is organizing a conference to be held at the Technische Hogeschool, Delft, during March 31–April 4, at which 55 papers to be distributed beforehand will be discussed. The conference is open to all who are interested : details of the programme and registration forms can be obtained from the Assistant Secretary, Institute of Physics, 47 Belgrave Square, London, S.W.1.

THE Parasitology Group of the Institute of Biology is holding its spring meeting at the University of Edinburgh during March 19–22. Twenty-five communications and several laboratory exhibitions have been selected ; the proceedings of the meeting will not be published. Those wishing to attend the meeting should register before February 28. Further information on the programme can be obtained from Miss June Mahon, Bedford College, Regent's Park, London, N.W.1.

Two symposia, on "Water and Woodlands" and on "Lysimeters", respectively, organized by the International Association of Scientific Hydrology will be held at Hannoversch–Münden, near Kassel, in Germany, during September 8–13. Intending contributors should submit summaries to the Assistant Secretary, The Royal Society, Burlington House, Piccadilly, London, W.1, from whom further information can be obtained. Completed papers must be submitted by the middle of April.

THE eleventh Technical Exhibition of the Oil and Colour Chemists' Association will be held in the New Hall of the Royal Horticultural Society at Greycoat and Elverton Streets, London, S.W.1, during March 17–19. The theme of the Exhibition will be the presentation of technical advances in those industries supplying the paint, varnish, printing ink, linoleum and other allied industries. The technical advances may relate to new products, new knowledge relating to existing products and their uses or, in suitable cases, existing knowledge which is not generally available in the consuming industries. Admission is free for both members and visitors. Further information can be obtained from the general secretary, Mr. R. H. Hamblin, Memorial Hall, Farringdon Street, London, E.C.4.

THE Acoustics Group of the Physical Society is sponsoring two symposia dealing with the problem of noise and vibration. The first, at 2.15 p.m. on March 24 in the Physics Department, Imperial College of Science and Technology, London, on "Recent Studies of Noise Problems", will survey recent work on the measurement and effects of noise. It is open to all without formality. The second is a one-day meeting on April 7 in the University of Southampton. Entitled "New Techniques in the Analysis of Noise and Vibration", it will include contributions on aspects of the use of correlation techniques, of digital computers for data processing and analysis, and on general applications of statistical communication theory. It is a joint meeting with the Institute of Physics. Further information can be obtained from D. M. A. Mercer, Physics Department, University of Southampton.

ERRATUM. In the communication by M. V. Carter entitled "Chemical Destruction of Mature Perithecia of *Mycosphaerella pinodes*", in *Nature* of January 17, p. 162, a line of description was omitted from the headings of columns 3–7 in Table 2. These headings, which refer to concentrations of pentachlorophenol, should read 0·1, 0·2, 0·5, 1·0 and 2·0 per cent, respectively.

LEGUMES IN AFRICAN AGRICULTURE

A TECHNICAL meeting on "Legumes in Agriculture and Human Nutrition" was held recently at Bukavu, Belgian Congo, under the joint auspices of the Food and Agriculture Organization of the United Nations and the Commission for Technical Co-operation in Africa South of the Sahara. Delegates attended from the Belgian Congo, French territories in Africa south of the Sahara, Nigeria, Federation of Rhodesia and Nyasaland, Northern Rhodesia, Southern Rhodesia and Portuguese territories in Africa.

The Agricultural Section at this meeting, under the chairmanship of Mr. A. Angladette, of the Office de la Recherche Scientifique et Technique Outre-Mer, had a very full agenda since attention had to be given to the cultivation of legumes for human food (grain or green vegetable), grazing and fodder production, as well as the improvement of soil fertility through the cultivation of these crops in rotations or as green manures.

Statistics with regard to acreages and production of grain legumes are entirely inadequate; but a general trend may be seen towards increased cultivation of cash crops and the progressive elimination of grain legumes, with the exception of the groundnut where it is grown commercially for export or for oil extraction. Grain legumes may be grown in the garden plot close to the house, in association with other crops and on soils rich in organic matter, or in the 'outfield' in the cropping phase of shifting cultivation.

The most widespread leguminous grain crops at the present time are groundnuts and cowpeas (*Vigna sinensis*), with the haricot bean (*Phaseolus vulgaris*) at the higher altitudes. Interest in *Voandzeia* and the acreage of this plant are decreasing. The greatest need for grain legumes is, however, in the low-lying wet tropics where there are no livestock or grain crops, and the people live on starchy foods such as cassava.

The delegates to the Nutrition and Agricultural Sections of the meeting recognized that some twenty African grain legumes could be regarded as of primary importance from both a nutritional and an agricultural point of view, and that these therefore represented a good basis for future development. The meeting, and particularly the delegates from the Belgian Congo, nevertheless stressed the need for a thorough search in local floras for new legumes for use as food, fodder, shade and cover plants and green manure crops. Any new material which might be found should be the object of study by the plant breeders, who should concern themselves with both quantity and quality (higher protein content and acceptable palatability). Attention should also be given to the production of varieties adapted to methods of cultivation and harvesting involving draught animals or powered machinery.

It would be desirable to facilitate the interchange of seeds of present or new types of plants between the different parts of the region. Seed samples should always be accompanied by adequate data regarding the ecological conditions of the station of origin or place of collection, and also, if possible, by a herbarium specimen for checking purposes. The need to establish herbaria for species and cultivars was also stressed.

The extent of cultivation of legumes for grazing or cut fodder varies considerably as between the different territories. Considerable success was reported in the sod-seeding of *Stylosanthes gracilis* in the existing pastures in the savannah zone. The pigeon pea (*Cajanus cajan*) is grown as spaced hedges in pure Rhodes grass (*Chloris gayana*) pastures in Southern Rhodesia. *Centrosema pubescens* and *Pueraria javanica* are promising for the wetter areas, with *Stizolobium deeringianum* as cut fodder. An important factor limiting the greater use of grazing and fodder legumes is the lack of adequate seed supplies. The meeting, therefore, stressed the need for promoting greater production and better distribution of seeds of legumes adapted to the various regions, supported by a service designed to control quality. Research on seed biology (hard seeds, viability, etc.) is also necessary.

It was agreed that the foremost problem is at present to grow better the legumes already available. There are wide differences between the yields obtained by the average cultivator and those which may be obtained with improved methods of cultivation. Correct and adequate mineral nutrition and an optimal legume/*Rhizobium* relationship are among the primary factors to be considered in this connexion. The policy of fitting the soil to the legume is much more difficult in African peasant agriculture than under more intensive systems of farming. It is also desirable to fit the legume to the soil by the selection, for example, of varieties adapted to either high or low levels of soil fertility. Economic considerations are important in this respect.

On these aspects the meeting recommended that more attention should be paid to fundamental research on legume nutrition and on the factors affecting the development of their associated *Rhizobia*. Workers in Africa south of the Sahara have requested the United Nations Food and Agriculture Organization to publish and keep up to date a world list of scientific institutes pursuing studies on *Rhizobia*, as well as a catalogue of the strains that these institutes have available.

Many examples were quoted of the serious economic losses caused by fungous diseases and insect pests both in the field and in the store. In the latter connexion, it is desirable to evolve cheap methods of grain storage for peasant farmers; for example, oil drums with screw tops into which beans could be placed when quite dry, and in which any beetles or other insects would be smothered. It is desirable that countries should publish a list of the pests and diseases of legumes and evaluate the economic importance of the losses they cause, carry out studies of the biology of the most important ones, develop methods for their prevention and control, and prevent the introduction of pests and diseases from other countries or territories by observing international phytosanitary regulations.

It is obvious that legumes can contribute greatly to the improvement of human and animal nutrition and to the fertility of the soil in Africa south of the Sahara, as in other parts of the world. Many questions, however, remain unanswered, and the need now is for a well co-ordinated programme of research, dealing with as many aspects as possible but avoiding duplication of effort. The delegates to this meeting repeatedly stressed the need for governments to provide more funds and facilities for this research. They also indicated to the organizations sponsoring this meeting that regional conferences or special study groups could with advantage give attention in due course to the correct utilization and development of the grazing and fodder resources of Africa south of the Sahara, and also to the specific problems of mineral nutrition in relation to legume *Rhizobia*, and the incidence, biology and control of pests and diseases of African legumes.

A report of this meeting will be available shortly in English, French and Spanish.

T. R. G. Moir

GELATINE AND GLUE RESEARCH

The sixteenth meeting of the Research Panel of the British Gelatine and Glue Research Association was held on December 12, with Mr. S. G. Hudson (Richard Hodgson and Sons, Ltd.) in the chair. Three papers were presented, each by members of the staff of the Association, and were discussed by an audience representative of both the industrial and academic aspects of the work.

The first paper, on "Solubilized Collagen", by Dr. A. Courts and Dr. G. Stainsby, was presented by Dr. Courts, who mentioned briefly the preparation of soluble collagen, especially from the skin and other collagenous tissues of young animals. He then described the modification of the corresponding tissues of adult animals, by cold alkaline pretreatment, to enable the usual solvents for soluble collagen (citric acid and citrate buffers) to extract substantial fractions of the pretreated collagen in the cold. The solutions obtained showed qualitatively similar behaviour to soluble collagen, such as high viscosity in very dilute solution, precipitation in fibrous form on dialysis against distilled water, or on the addition of salt, and conversion to gelatin on warming. Quantitatively, the intrinsic viscosity, while varying to some extent according to raw material and mode of pretreatment, was in agreement with the results of Doty and Nishihara[1] for soluble collagen from calf-skin. Ossein, the demineralized organic component of bone, gave, in a typical experiment, a 30 per cent conversion to solubilized collagen, and there was no reason to regard this as the ultimate limit possible. Sinew and skin were more difficult to convert, but the same general behaviour was observed. The pretreatment processes, if not in detail reversing the process by which collagen is laid down in insoluble form, leave fragments which may have structural significance for the original tissue. The temperature of conversion from the solubilized collagen to gelatin in citrate buffer at *p*H 3·7 was in the region of 30° C., which is lower than that reported for soluble collagen from calf-skin. There is probably only a slight difference in temperature of conversion at neutral *p*H values. The change in optical rotation was measured by Dr. A. Todd, and gave values of specific rotation $[\alpha]_D$ for the soluble collagen and derived gelatin close to those of Doty and Nishihara[1], although confirming the lower conversion temperature of 30° C. noted above.

Mr. A. A. Leach read the second paper, on "The Examination of Gelatine by Passage through Amberlite Resins of the 'I.R.C. 50' (Carboxylic) Type". The paper consisted of a critical examination of the separation of gelatin into two components, by *XE*.97 resin, reported by Mr. G. Russell (Ilford, Ltd.) at the fourteenth meeting of the Research Panel and in a short account in *Nature*[2]. In a typical experiment, a small quantity of gelatine was placed at the top of a resin column previously equilibrated to the required *p*H. Buffer solution at the same *p*H was then passed through the column, fractions collected, and the concentration of protein estimated by the Lowry method, or collected for further analysis. To obtain sufficient of any minor components, large columns of resin were used. It was shown that from *p*H 3 to 5·25 a very small proportion (about 0·3 per cent) of the gelatine used (laboratory sample 127) passed through the column with negligible adsorption, while the remainder was firmly adsorbed as long as the column was not overloaded. Amino-acid analysis of the small eluted fraction gave only a very low content of hydroxyproline, little glycine or proline, and high valine, leucine, *iso*leucine, tyrosine, threonine and aspartic acid compared with the whole gelatine. The analysis is similar to that of Maron[3] for an impurity isolated by adsorption on charcoal.

At higher *p*H, increasing amounts of gelatine 127 are separated in the first peak, while retaining a sharp separation from the remaining adsorbed gelatine. By *p*H 6, 93 per cent of the gelatine was eluted. The percentage eluted could also be increased by overloading a column. Chemical analysis showed that, as soon as several per cent of the gelatine is contained in the first peak, either by overloading or by raising the *p*H, the bulk of the eluted fraction is a substance of gelatin type containing hydroxyproline, with a composition almost identical with the parent gelatin. There was evidence that molecular weight played some part in the separation and a possibility that minor differences in amino-acid composition were also present. No evidence was found suggesting the presence of the 10–20 per cent of a non-gelatin-like component reported by Russell.

The differences between resin batches were shown to be, in the main, accountable in terms of surface area. Two further gelatines (laboratory samples No. 142, *p*I 7·8 and No. 149, *p*I 9·4) of acid-process type showed similar behaviour to gelatin 127 (*p*I 4·95) but the corresponding percentages eluted were found at higher *p*H.

The third paper, "Some Factors influencing the Melting of Gelatin Gels", read by Dr. G. Stainsby, was based on his work with Mr. J. T. Taylor. After reviewing the arbitrary character of melting-point measurement, Dr. Stainsby described the Association's method, which uses as indicator the flow of a drop of carbon tetrachloride down the thin molten layer in contact with the wall of the thin-walled test-tube in which the gel has been set and matured.

The tube is held in a water-bath, the temperature of which is raised ½ deg. C./min. The method has the advantage of simplicity, thus enabling many variables to be studied. The main contribution of the paper was to show in which conditions the period of maturing of a gel has the most marked effect on its structure as shown by the melting point. If the gelatine solution is rapidly cooled, and then matured at a temperature of 0–10° C., the maturing, after the first hour, has no effect on the melting point, except for the most dilute gels where the setting takes an appreciable time. In contrast, at the higher maturing temperatures (20–25° C.) a marked increase in melting point may be secured by prolonged maturing. These differences in behaviour are presumed to arise from greater powers of re-orientation into stable aggregates at the higher temperature.

Interesting results were obtained by successive maturing at two temperatures. Whereas the melting point characteristic of high-temperature maturing was not changed when this maturing was followed by a further maturing period at a low temperature, the same was not true when the temperatures were reversed. High-temperature maturing could cause a rise in melting point even when it succeeded low-temperature maturing.

The formation of aggregates on cooling gelatin solutions to temperatures above their setting point can be detected by viscosity measurement. In addition, aggregates formed at 25° C. can persist for appreciable times even at 40° C. This work has a bearing on many uses of gelatine and glue, as well as on gel structure.

NATIONAL RESEARCH COUNCIL OF CANADA

REPORT FOR 1957–58

THE forty-first annual report of the National Research Council of Canada, covering the year 1957–58*, includes the report of the president, Dr. E. W. R. Steacie, the financial statement, and the annual report of Canadian Patents and Development Ltd. Although the latter company shows a slight loss for the year, the prospects of increasing revenue from licences for oil additives, the crash position indicator, the multiple core yarn and the sedimentation device are stressed. During the year the Council provided 3·6 million dollars in support of pure research in the universities by way of 305 scholarships and fellowships, and its 583 scientific research staff (including 142 post-doctorate fellows), 854 technical and 888 general service and administration staff answered 9,500 technical inquiries from Canadian industries. For 1958–59 the Council has recommended that the support given to the universities should be increased to 6 million dollars, but continued growth of government research laboratories is also essential in view of certain limitations on research in industry in Canada.

In 1956, Dr. Steacie points out, Canadian secondary industries, which contribute 22 per cent of the net output and employ 20 per cent of civilian labour, spent about 80 million dollars on research, an increase of 20 per cent on 1955, but 65 per cent of this expenditure was made by a relatively few large companies. Compared with the United States or Great Britain expenditure on research by industry is relatively low.

A major effort is needed to bring about the type of expansion required, and the maintenance of a supply of competent scientists is a reason for ensuring that every encouragement is also given to research in the universities and in Government laboratories.

The Division of Applied Biology has undertaken fundamental work on the effects of irradiation on the development of rancidity in bacon and continued its investigation of railway refrigerator cars. Studies of the structure and development of plant cells and their constituents with the electron microscope were extended, and an improved assay procedure was developed for the toxin-neutralizing substance discovered in culture filtrates of *Penicillium cyanofulvum*, while conversions of up to 50 per cent of sugar to citric acid have been obtained by submerged fermentation of blackstrap molasses. The Atlantic Regional Laboratory completed a systematic survey of the composition of peat in seven large bogs in the Maritime Provinces and its further studies on laminarin sulphate as a blood-anticoagulant have shown that with large doses over a prolonged period this substance tends to be more toxic than heparin. The Prairie Regional Laboratory has developed special columns for the rapid analysis of components of vegetable oils by gas – liquid phase chromatography, and promising yields of lysine and ergot have been obtained by careful study of fermentation conditions, while a new method was developed for the direct separation of starch and gluten from wheat flour.

In the Division of Applied Chemistry, a silver catalyst was used in studying the oxidation of ethylene and propylene, and high-pressure work has included the conversion of gaseous and liquid aldehydes to solids, the measurement of rates of selected reactions as a function of pressure and the determination of changes in the physical properties of gases when highly compressed. The molecular weights of chemical compounds and polymers in the range 40,000–100,000 have been determined and the oxidation-rates of iron and its alloys measured over a range of temperatures by following the gain in weight and by cathodic reduction of the oxidation products. An extensive study was made of the kinetics of polymerization of styrene and α-methylstyrene initiated by sodium naphthalene and much work was done on the fabrication of silver alloys for oxidation catalysts.

In the Division of Pure Chemistry, work continued on the development of suitable methods for deuterating organic compounds, and a study was made of the instrumental conditions to be met to obtain infra-red spectra that are true physical constants of the absorbing compounds. Comprehensive measurements are being made of the specific heat of elements of the diamond structure (diamond, silicon and germanium) in the temperature region 2°–300° K. and a Calvet type microcalorimeter is being constructed. The study of the influence of surface forces on the rates of flow of fluids through capillary systems and of the nature of the forces responsible for the sorption of acids and dyes by textile fibres continued.

* Forty-first Annual Report of the National Research Council of Canada, 1957–58, including the Annual Report of Canadian Patents and Development Limited. Pp. 54. (N.R.C. No. 4783.) (Ottawa: Queen's Printer, 1958.)

In its work on the control of noise, the Division of Applied Physics gave some attention to communication in high ambient noise. The process of establishing Canada's standards in electricity and mechanics is approaching completion. Temperature measurements of very high precision are being made to determine some of the limits of accuracy of the International Temperature Scale and to investigate the possibility of replacing later some of its fixed points. Besides work on the redefinition of the international metre, comprehensive studies on aerial triangulation continued, and detailed studies by the photometry laboratory should lead to an improved primary standard of light.

The Division of Pure Physics reports important advances in studies of the interaction of energetic μ-mesons with carbon nuclei; an extensive experimental study of the transition metals was completed; a new theory of the processes of strain hardening has been developed and a new type of phase transition in solids discovered. The structures of propiolic aldehyde and vinyl cyanide were determined in the microwave laboratory. A new approach to the general theory of relativity has been formulated on the basis of a new principle of observation.

In the Division of Mechanical Engineering, a very thorough investigation was made into the status of production, research and development in non-metallic structural materials in Canada, and work was almost completed on several projects for the St. Lawrence Seaway. Besides problems related to the design and powering of ships, substantial work was undertaken on the examination of aircraft turbo-jet and turbo-propeller engines under simulated icing conditions. Work is in progress on the aerodynamic problems of aircraft capable of vertical take-off and short take-off, and on techniques for measuring the dynamic characteristics of aircraft at high speeds. An emergency radio beacon, simple and light in weight, was developed by the Radio and Engineering Division to survive aeroplane crashes, as well as a device using transistors to switch off electric buoy lights during daylight and a photoelectric control which puts the diesel-electric plant at Pelee Passage lighthouse into operation between dusk and dawn. Microwave equipment is being developed to provide accurate fixes of position for hydrographic vessels, and a method was devised for measuring the gradient of voltage across each unit of a high-voltage suspension insulator string. Daily observations of 10-cm. radio-emission from the Sun were continued at the Radio Astronomy Observatory, and completion of the Springhill Meteor Observatory provided a new headquarters for meteor research, while auroral radar units are being operated continuously at four stations.

ACTION OF LIGHT ON VISUAL PIGMENTS

from

THE BIOLOGICAL LABORATORIES, HARVARD UNIVERSITY

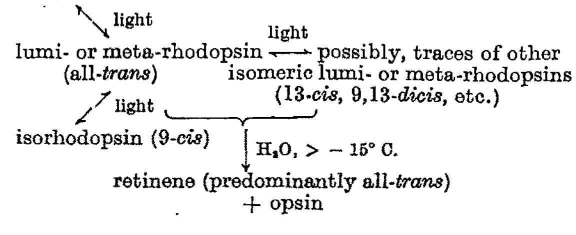
Vertebrate Lumi- and Meta-rhodopsins

By DR. RUTH HUBBARD, PAUL K. BROWN and DR. ALLEN KROPF*

RHODOPSIN, the red photosensitive pigment of rod vision, consists of the colourless protein, rod opsin or scotopsin, carrying neo-*b* (11-*cis*) retinene as chromophore. In the light, rhodopsin bleaches through orange-red intermediates (lumi- and meta-rhodopsin) to the yellow mixture of all-*trans* retinene and opsin.

The bleaching of rhodopsin proceeds in three steps, the first photochemical, followed by two thermal reactions[1]. Light initiates this reaction sequence by isomerizing the *cis* chromophore of rhodopsin to the all-*trans* configuration, so converting rhodopsin to the all-*trans* chromoprotein, lumirhodopsin[2,3]. Below about −40° C. lumirhodopsin is stable[1]; above this temperature it changes in light or darkness to a second all-*trans* chromoprotein, metarhodopsin[1-3]. Below about − 15° to − 20° C. metarhodopsin is stable[1]. At higher temperatures, all known vertebrate metarhodopsins hydrolyse spontaneously in the dark to all-*trans* retinene and opsin. Only this last reaction entails a major change in colour, that is, bleaching. Visual excitation, however, is so rapid as to leave time only for the first or second step, and must therefore precede bleaching[1,2].

Light, having isomerized the *cis* chromophore of rhodopsin to the all-*trans* configuration (lumi- or meta-rhodopsin), can go on to isomerize this to *cis* configurations, thus forming rhodopsin (11-*cis*), and isorhodopsin (9-*cis*). In conditions under which lumi- or meta-rhodopsin are stable, prolonged irradiation therefore always yields stereoisomeric mixtures of lumi- or meta-rhodopsin with photoregenerated rhodopsin and isorhodopsin. This situation can be summarized as follows[2,3]:



rhodopsin (11-*cis*)
light
lumi- or meta-rhodopsin
(all-*trans*)
light
possibly, traces of other isomeric lumi- or meta-rhodopsins (13-*cis*, 9,13-*dicis*, etc.)
light
isorhodopsin (9-*cis*)
H₂O, > − 15° C.
retinene (predominantly all-*trans*) + opsin

---

* Present address: Chemistry Department, Amherst College, Amherst, Mass.

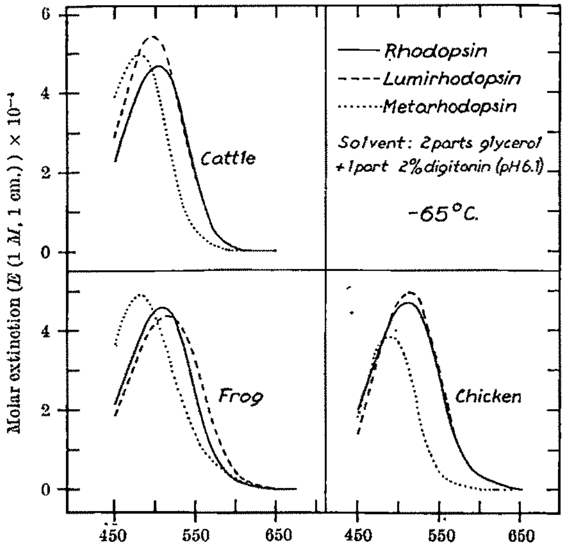


Fig. 1. Absorption spectra of rhodopsins, lumirhodopsins and metarhodopsins from cattle, bullfrog (*R. catesbiana*) and chicken. Rhodopsin spectra were measured directly; lumi- and metarhodopsin spectra obtained as described in the text. All are averages of 2–4 experiments. The extinction coefficients of the rhodopsins at – 65° C. were derived from the extinction coefficients at room temperature, by cooling solutions of known extinction to – 65° C., and correcting for volume shrinkage of the solvent (4·5 per cent). The extinction coefficients of cattle and frog rhodopsin in glycerol–digitonin at room temperature ($\epsilon_{max.}$ = 42,000) were measured by methods previously described (ref. 7), and assumed to be the same for chicken rhodopsin. The extinction coefficients of the lumi- and meta-rhodopsins were obtained by measuring the extinction of rhodopsin which disappeared when a given extinction of lumi- or meta-rhodopsin was formed (cf. Fig. 3). Cattle rhodopsin was prepared from isolated rod outer limbs (ref. 10); bullfrog rhodopsin from alum-hardened retinas (ref. 14). Chicken rhodopsin was obtained by incubating a preparation of mixed rod and cone opsins (ref. 15) with excess neo-*b* retinene. This yields a mixture of chicken rhodopsin and iodopsin. The iodopsin, which is labile in the presence of hydroxylamine (ref. 15), is then destroyed by incubating the mixture ½ hr. at room temperature with 0·3 *M* hydroxylamine

We have recently examined lumi- and metarhodopsins from five species of vertebrates, and two cephalopods. These are described in the present and following communications. However, we must first clarify our terminology.

We use the terms *lumirhodopsin* and *metarhodopsin* to designate the two all-*trans* chromoproteins resulting from the photoisomerization of rhodopsin. As will be seen, the spectroscopic properties of these compounds—wave-length of maximum absorption ($\lambda_{max.}$) and molar extinction coefficient at $\lambda_{max.}$ ($\epsilon_{max.}$)—differ somewhat from one species to another. Rhodopsins also exhibit species variations in these properties[4,5]; yet we designate as a *rhodopsin* any visual pigment composed of neo-*b* retinene and a rod opsin. The fact is that rod opsins, like most proteins, differ somewhat from one species to another, and this leads to species differences in the absorption properties of the rhodopsins, and lumi- and metarhodopsins.

Experimental results. The absorption properties at – 65° C. of the rhodopsins, lumirhodopsins, and metarhodopsins from five species of vertebrates are shown in Figs. 1 and 2, and summarized in Table 1. The information in each case is obtained from the type of experiment illustrated in Fig. 3.

Table 1. ABSORPTION PROPERTIES OF THE VISUAL CHROMOPROTEINS FROM FIVE SPECIES OF VERTEBRATES, MEASURED IN 2 : 1 GLYCEROL–DIGITONIN AT – 65° C.

Half-widths of the absorption bands are obtained, by subtraction, from the two wave-lengths or frequencies at which the extinction is half maximal

Species	$\lambda_{max.}$ (mμ)	$\epsilon_{max.}$ (litre/ mole-cm.)	Half band-width wave-length (mμ)	Half band-width frequency (10^{14}/sec.$^{-1}$)
		Rhodopsins

Rhodopsin in 2 per cent aqueous digitonin is mixed with two volumes of glycerol, and to 0·3 ml. of this solution 0·005 ml. 1 *M* hydroxylamine is added. The solution and a blank of 2 : 1 glycerol–digitonin are cooled to – 65° C. in the modified, insulated cell compartment of a Beckman *DU* spectrophotometer, by circulating through Beckman thermospacers acetone from a reservoir chilled with solid carbon dioxide. The temperature in the cell compartment is measured with an iron-constantan thermocouple attached to the Beckman cell holder (reference junction at 0° C.). The absorption spectrum of the rhodopsin preparation is measured (Fig. 3, spectrum 1), and the rhodopsin is then irradiated in place in the cell compartment until all spectroscopic changes are essentially completed (Fig. 3, spectrum 2). The irradiation is performed with light from a 100-watt

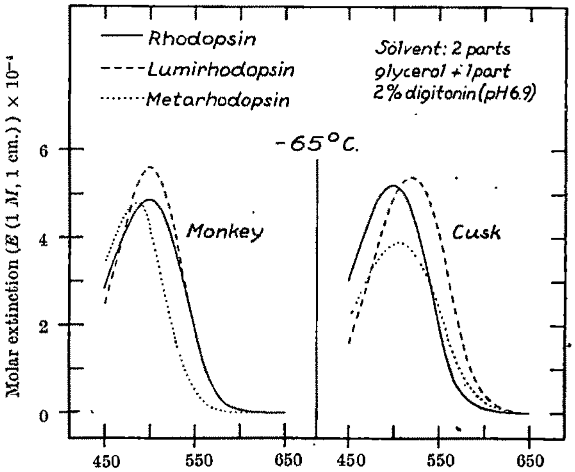

Fig. 2. Absorption spectra of rhodopsins, lumirhodopsins and metarhodopsins from monkey (*Rhesus*) and cusk (*Brosme brosme* Müller). Spectra obtained as in Fig. 1. Monkey rhodopsin was prepared by incubating rod outer limbs, isolated from light-adapted, frozen and thawed retinas, with excess neo-*b* retinene (refs. 8 and 10). The rods were then washed with buffer and water, hardened in alum, lyophilized, and extracted with petroleum ether. Rhodopsin was finally extracted with 2 per cent digitonin. Cusk rhodopsin was synthesized in solution by incubating cusk opsin, extracted from isolated rod outer limbs, with a limiting amount of neo-*b* retinene (refs. 4 and 16)

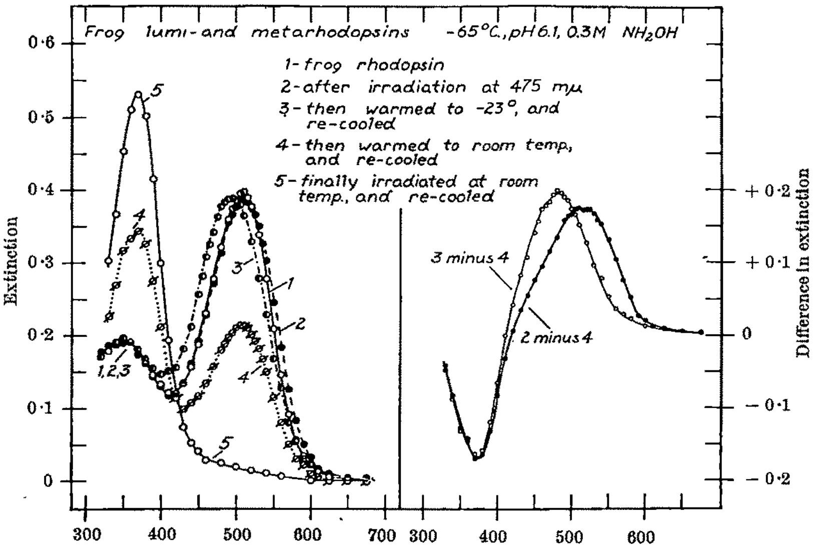

Fig. 3. Formation of bullfrog lumi- and meta-rhodopsin. Experimental details are described in the text. The sample was irradiated 1 hr. at 475 mμ (half band-width about 6 mμ)

zirconium arc, dispersed by a Bausch and Lomb grating monochromator (1,200 lines per mm., 250 mm. focal length), which enters the cell compartment through a window, on opening a photographic shutter.

Prolonged irradiation at − 65° C. produces mixtures composed of lumirhodopsin, photoregenerated rhodopsin, and isorhodopsin (Fig. 3, spectrum 2). Upon warming the mixture in the dark to between about − 30° and − 20° C., the lumirhodopsin is converted to metarhodopsin, whereas the other two components remain unchanged. This change in temperature is achieved by shutting off the flow of cold acetone until the desired temperature is reached, and maintaining it either with sporadic bursts of cold acetone, or by circulating ethylene glycol from a constant-temperature bath (American Instrument Co.) at about − 30° C.

The sample is then re-cooled to − 65° C., and the spectrum again measured (Fig. 3, spectrum 3). (The absorption spectra of these pigments are somewhat dependent on temperature[1,6]. Successive spectra must therefore be compared at the same temperature.) The sample in its absorption cell is now removed from the cold cell compartment, and kept at room temperature in the dark for about ½ hr. As mentioned above, under these conditions vertebrate metarhodopsins hydrolyse to opsin and all-*trans* retinene, which in the present experiments immediately reacts with hydroxylamine to form retinene oxime[7]. After re-cooling the solution to −65° C. (Fig. 3, spectrum 4), one observes the absorption bands of retinene oxime ($\lambda_{max.}$ 369 mμ), and rhodopsin and isorhodopsin, the latter having previously been masked by lumi- and meta-rhodopsin. Rhodopsin and isorhodopsin are finally converted to all-*trans* retinene oxime by irradiation at room temperature (Fig. 3, spectrum 5).

Fig. 3 (right) shows the difference spectra of bull-frog lumi- and meta-rhodopsin, obtained by subtracting spectrum 4 from spectra 2 and 3. Since these difference spectra are measured in the presence of hydroxylamine, they are equivalent to absorption spectra at wave-lengths longer than about 450 mμ, at which retinene oxime has negligible absorption[8]. All the results in Figs. 1 and 2 were obtained from this type of experiment.

That the product of irradiating rhodopsin in the cold is not a single substance, but such a mixture of chromoproteins as we have described, is further demonstrated in Fig. 4. Here cattle rhodopsin at −65° C. is irradiated at 450 mμ or 500 mμ. It is clear that the absorption spectra of the resultant products (spectra 2) depend upon the wave-length at which they are produced[2]. After warming the products, to convert lumirhodopsin to all-*trans* retinene oxime (spectra 3), one sees that the difference in spectrum is caused by a difference in composition: irradiation at longer wave-lengths favours the production of isorhodopsin (the component which absorbs at shortest wave-lengths ($\lambda_{max.}$ 490 mμ at − 65° C.)), whereas irradiation at shorter wave-lengths favours rhodopsin (see also Fig. 6 of ref. 2). Lumirhodopsin, in both cases, possesses a difference spectrum of the same shape and $\lambda_{max.}$ (Fig. 4, right).

Discussion. The shapes and wave-length maxima of the absorption spectra of the chromoproteins from the five vertebrates we have examined are summarized in Fig. 5. As can be seen from Fig. 5 and

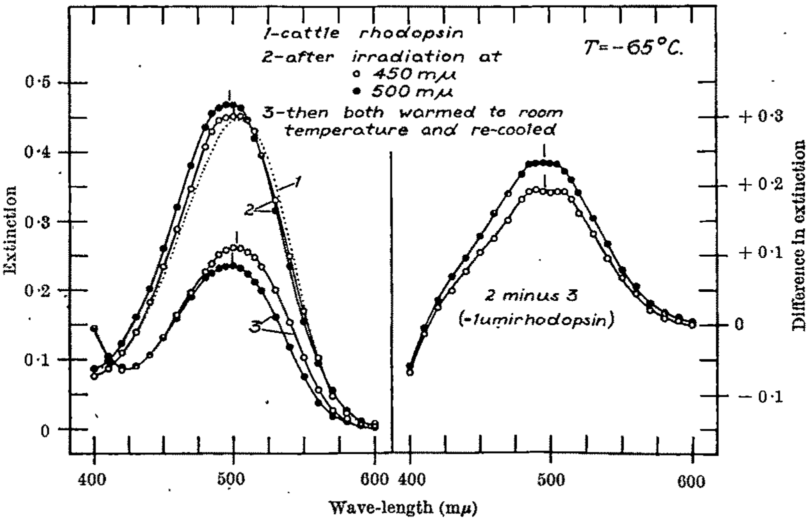

Fig. 4. Mixtures of chromoproteins obtained by irradiating cattle rhodopsin at 450 and 500 mμ. Experimental details are described in the text. Irradiation at 450 mμ was continued 1½ hr.; at 500 mμ, 1 hr.; both at half band-widths of about 6 mμ. Neither irradiation was sufficiently long to yield the steady state mixture of chromoproteins (cf. refs. 2 and 3)

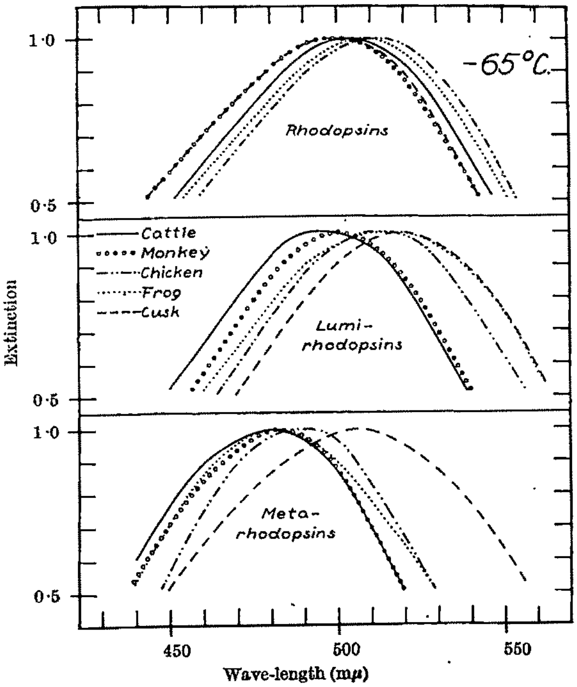

Fig. 5. Absorption spectra of the visual chromoproteins from five species of vertebrates. For comparison, all spectra are brought to an extinction of 1·0 at $\lambda_{max.}$

Table 1, the half-widths of the absorption bands (particularly on a frequency basis) exhibit little, if any, species variation, and furthermore are similar for all three classes of pigments. (The most outstanding exception is cusk metarhodopsin, and for the following reason. Metarhodopsins from different species differ somewhat in their thermostabilities. Thus, frog and especially cusk metarhodopsins hydrolyse more readily than the others. In the experiments with cusk chromoproteins, it is therefore difficult to find a temperature at which lumirhodopsin is converted completely to metarhodopsin, before some of the metarhodopsin has already hydrolysed to retinene and opsin. It is therefore likely that the spectrum of cusk 'metarhodopsin' in fact represents a mixture of lumi- *and* meta-rhodopsin. This would account for its width, and for the fact that its $\lambda_{max.}$ lies at a considerably longer wave-length than those of the other metarhodopsins.)

That $\lambda_{max.}$ varies with species is obvious for all three pigments. We have suggested elsewhere that the colour of the visual chromoproteins depends on an intimate steric fit between the chromophore and the opsin, which permits them to interact in such a way as to increase the resonance stabilization of the first excited state of the chromophore[3,9]. Species differences in the opsins modify the colours of these compounds, presumably by affecting these steric relationships with the chromophore.

The sets of chromoproteins from any one species exhibit some regularities. Thus, $\lambda_{max.}$ of lumirhodopsin in general lies at the same or longer wave-length as that of the corresponding rhodopsin; and always at a longer wave-length than that of the corresponding metarhodopsin.

We have postulated that the transformation of rhodopsin to lumirhodopsin involves, primarily, a configurational change of the chromophore; the transformation of lumirhodopsin to metarhodopsin, a change in configuration of the opsin[2]. In brief, this conclusion is based on the following arguments.

At the temperatures at which lumirhodopsin is stable (that is, below about − 45° C.), the glycerol–digitonin system forms a highly viscous liquid, or glass, which melts over the temperature-range in which lumirhodopsin changes to metarhodopsin. In the glass at low temperatures, the opsin probably has little or no freedom to change configuration, so that one can isolate the primary photochemical event—the photoisomerization of the chromophore. As the temperature is raised, however, the opsin becomes re-arranged to a new, more stable configuration.

Numerous lines of evidence indicate that the configuration of the protein is different in rhodopsin and opsin[10-12]. Furthermore, it has been shown with the squid chromoproteins that opsin reacts differently in rhodopsin and metarhodopsin[13]. This suggests that the polypeptide chain of opsin assumes one configuration in the presence of the 11-*cis* chromophore (rhodopsin), another in combination with the all-*trans* chromophore (metarhodopsin), and a third in the absence of a chromophore (opsin). When, as a result of irradiation at − 65° C., the *cis* chromophore of rhodopsin is isomerized to all-*trans* (lumirhodopsin), the configuration of the protein is unstable, but cannot become rearranged to that of metarhodopsin until the system is rendered more fluid by raising the temperature.

A further observation is in line with the above interpretation. Rhodopsin and lumirhodopsin are freely interconvertible by irradiation at − 65° C., as shown above. Likewise, rhodopsin and metarhodopsin are readily interconverted by irradiation at − 20° C.[2,3]. However, we find that *irradiation of metarhodopsin at − 65° C. does not yield rhodopsin,* just as irradiation of rhodopsin at this temperature fails to yield metarhodopsin. We conclude that the low temperature blocks re-arrangement of opsin *in both directions*. A thermal loosening of structure is required to render the two states interconvertible.

The reaction sequence involved in the bleaching of vertebrate rhodopsin can be summarized as follows:

Reaction	Product	Colour
	Rhodopsin (11-*cis*)	red
1. Photochemical stereoisomerization of the chromophore	⇅	
	Lumirhodopsin (all-*trans*)	red to purple
2. Thermal rearrangement of the opsin	↓	
	Metarhodopsin (all-*trans*)	orange to red
3. Hydrolysis of the chromophore from opsin	↓	
	Retinene (all-*trans*) + Opsin	yellow

Species differences in opsin introduce minor differences in the absorption properties and thermal stabilities of the individual chromoproteins; but the general scheme is the same for all the vertebrate rhodopsins we have examined.

As mentioned above, visual excitation almost surely precedes the release of retinene, and apparently is triggered by the transformation of rhodopsin to lumi- or meta-rhodopsin. The rearrangement of the protein in going from lumi- to meta-rhodopsin could conceivably be the triggering reaction, perhaps by unmasking new reactive groups, or changing the charge distribution of the molecule, and so producing a transient, localized pocket of positivity or negativity in the rod outer limb.

The experiments described in the present and two succeeding communications were performed with the financial support of grants to Prof. George Wald from the Rockefeller Foundation, the Office of Naval Research, and the Division of Neurological Diseases and Blindness of the U.S. Public Health Service (Grant *B*-568 *C*4); and while one of us (A. K.) was Fellow in Cancer Research of the American Cancer Society. We should like to thank Prof. George Wald for many helpful discussions and suggestions. We are grateful to Eli Lilly and Co., of Indianapolis, for supplying us with monkey eyes; and to the Phillips Poultry Supply, of East Boston, for gifts of fresh chicken heads.

Lumi- and Meta-rhodopsins of Squid and Octopus

By DR. ALLEN KROPF, PAUL K. BROWN and DR. RUTH HUBBARD

WE have extracted rhodopsins from four species of invertebrates: three cephalopods, namely, squid (*Loligo pealii*)[13,17], cuttlefish (*Sepia officinalis*)[18], and octopus (*Octopus vulgaris*)[18], and one decapod crustacean—the lobster (*Homarus americanus*)[19]. These rhodopsins, like those of vertebrates, are composed of neo-*b* (11-*cis*) retinene attached as chromophore to colourless proteins, members of the family of opsins[2,13,18]. Light isomerizes the *cis* chromophore to the all-*trans* configuration, so transforming invertebrate, like vertebrate, rhodopsins to the all-*trans* chromoproteins, lumi- and meta-rhodopsin[3,13] (see also first communication). However, whereas vertebrate metarhodopsins readily hydrolyse to all-*trans* retinene and opsin[1,2] (see also first communication) the four invertebrate metarhodopsins which have been examined are relatively stable[13,17–19].

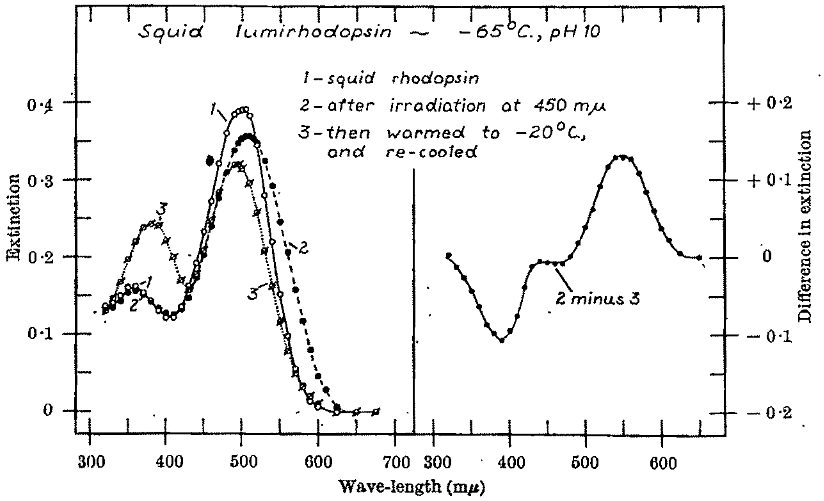

Fig. 6. Formation of squid lumirhodopsin, and its conversion to alkaline metarhodopsin. Squid rhodopsin in 2 per cent aqueous digitonin, prepared as previously described (ref. 13), was mixed with two volumes of glycerol and brought to *p*H 10 by addition of solid sodium carbonate. The solution was cooled to − 65° C. in the Beckman spectrophotometer (see first communication), and its spectrum measured against a blank of 2 : 1 glycerol–digitonin (spectrum 1). The preparation was then irradiated 2 hr. at 450 mμ (half band-width about 6 mμ), and its spectrum re-measured (spectrum 2). To convert lumirhodopsin to metarhodopsin, the solution was warmed to − 20° in the dark for about an hour, and its spectrum measured after cooling to − 65° C. (spectrum 3). Upon subtracting spectrum 3 from 2, one obtains the difference spectrum of lumirhodopsin, shown at the right

As previously shown, the further irradiation of metarhodopsin re-isomerizes its all-*trans* chromophore to the neo-*b* configuration, thus regenerating rhodopsin[3,13]. The cephalopod rhodopsin systems in their simplest form can therefore be summarized[13,18]:

$$\text{rhodopsin} \xrightleftharpoons{\text{light}} \text{metarhodopsin}$$

One other property is shared by the cephalopod metarhodopsins, though not by that of the lobster. All three are *p*H indicators, red ($\lambda_{\max.}$ about 500 mμ) in neutral or mildly acid solution, and yellow ($\lambda_{\max.}$ 380 mμ) in alkaline solution[13,18]. The interconversion of the two forms involves the reversible dissociation of a hydrogen ion, probably from the Schiff base linkage ($—CH{=}N— + H^+ \rightleftharpoons —CH{=}\overset{+}{N}H—$), which attaches the retinene chromophore to opsin[3,9,13,20]:

$$\underset{(\lambda_{\max.}\ \text{about}\ 500\ \text{m}\mu)}{\text{acid metarhodopsin}} \rightleftharpoons \underset{(\lambda_{\max.}\ 380\ \text{m}\mu)}{\text{alkaline metarhodopsin}} + H^+$$

The chromophore of rhodopsin appears to be a protonated Schiff base, like that of acid metarhodopsin[3,9]. The rhodopsin system of cephalopods therefore includes the reversible loss of a hydrogen ion[13,18]:

$$\begin{tikzcd}\text{rhodopsin} \arrow[r, shift left, "\text{light}"] & \text{acid metarhodopsin} \arrow[l, shift left, "\text{light}"] \arrow[r, shift left, "-H^+"] & \text{alkaline metarhodopsin} \arrow[l, shift left, "+H^+"] \arrow[ll, bend left, "\text{light} + H^+"]\end{tikzcd}$$

Preliminary experiments at low temperatures (− 45° C.) suggested that squid rhodopsin, like those of vertebrates, is converted by light to lumirhodopsin, and that a second, thermal reaction turns the latter into metarhodopsin[21]. We have investigated the lumi- and meta-rhodopsins from two cephalopods, squid and octopus, by the methods described in the preceding communication.

Experimental results. Squid rhodopsin in alkaline solution (2 : 1 glycerol–digitonin, *p*H 10) is chilled to −65° C. (Fig. 6, spectrum 1). Upon irradiation, the absorption spectrum changes as shown in Fig. 6: the extinction falls at wave-lengths shorter than 510 mμ, and rises at longer wave-lengths, owing to the formation of a mixture of chromoproteins, namely, lumirhodopsin, regenerated rhodopsin, and isorhodopsin (first communication). If this mixture is warmed in the dark to −20° C., rhodopsin and isorhodopsin remain unchanged, but lumirhodopsin at this *p*H is converted to alkaline metarhodopsin ($\lambda_{\max.}$ 380 mμ), as shown in spectrum 3 (Fig. 6). The difference spectrum of lumirhodopsin, obtained by subtracting spectrum 3 from 2, is shown at the right of the figure. Since alkaline metarhodopsin has essentially no absorption at wave-lengths longer than about 500 mμ (cf. Fig. 8), above that wave-length this difference spectrum is equivalent to the absorption spectrum of lumirhodopsin.

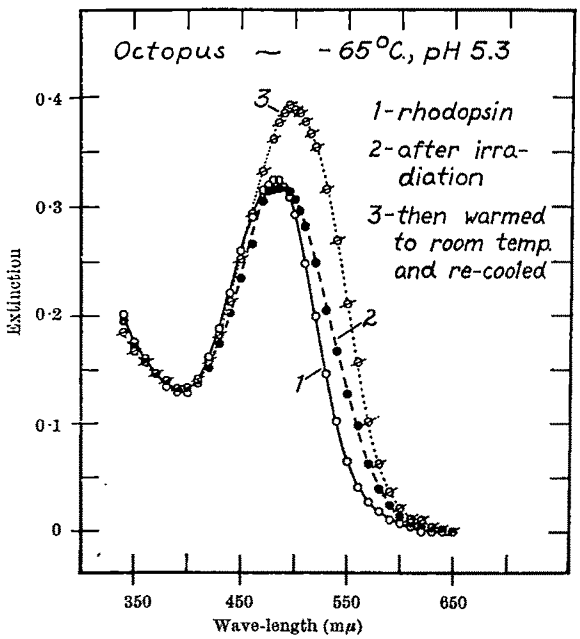

Fig. 7. Formation of octopus lumirhodopsin, and its conversion to acid metarhodopsin. Octopus rhodopsin in 2 per cent aqueous digitonin was prepared from eyes of frozen and thawed Portuguese octopus as previously described (ref. 18), and mixed with two volumes of glycerol. It was then brought to pH 5·3 by addition of 0·005 ml. 1 M acetate buffer (pH 4·7) to 0·3 ml. of solution, cooled to − 65° C., and its spectrum measured against 2 : 1 glycerol–digitonin as blank (spectrum 1). It was then irradiated 1 hr. at 470 mμ (6 mμ half band-width) and the spectrum re-measured (spectrum 2). The solution was now warmed to room temperature to convert lumirhodopsin to acid metarhodopsin, and the spectrum measured after re-cooling (spectrum 3). The increase in extinction at wave-lengths longer than about 450 mμ is due to the conversion of lumirhodopsin to acid metarhodopsin

The same experiment, performed with octopus rhodopsin, yields similar results, differing only in spectroscopic detail, since the absorption spectra of the chromoproteins from squid and octopus differ somewhat (cf. Table 2, and Figs. 8 and 9).

As with the vertebrate systems, the relative amounts of each isomeric chromoprotein in the mixture vary following irradiation at different wave-lengths. But the spectrum of each component—lumirhodopsin, rhodopsin, and isorhodopsin—is independent of the conditions under which it is produced (first communication).

Irradiation of squid or octopus rhodopsin at − 65° C. in neutral or mildly acid solution yields mixtures of chromoproteins identical with those obtained in alkaline solution. However, warming under these conditions converts lumirhodopsin to acid rather than alkaline metarhodopsin. In other words, the absorption spectra of the cephalopod lumirhodopsins are invariant with pH. Indicator properties appear only at the level of metarhodopsin. An experiment with octopus rhodopsin at pH 5·3 is shown in Fig. 7.

Table 2. ABSORPTION PROPERTIES OF RHODOPSIN, LUMIRHODOPSIN, AND THE METARHODOPSINS FROM SQUID (*Loligo pealii*) AND OCTOPUS (*Octopus vulgaris*) IN 2 : 1 GLYCEROL–DIGITONIN AT − 65° C. Half-widths of absorption bands, determined as described in the first communication, are given in terms of wave-length (mμ) and frequency (sec.$^{-1}$)

Absorption characteristics	Rhodopsin	Lumi-rhodopsin	Metarhodopsin Acid	Metarhodopsin Alkaline
		Squid		
$\lambda_{\text{max.}}$ (mμ)	500	550	500	385
$\varepsilon_{\text{max.}}$ (litre/mole-cm.)	48,000	64,000	65,500	66,500
Half band-width :				
(mμ)	102	83	102	76
(10^{14} sec.$^{-1}$)	1·28	0·84	1·29	1·61
		Octopus		
$\lambda_{\text{max.}}$ (mμ)	483	508	505	
$\varepsilon_{\text{max.}}$ (litre/mole-cm.)	43,000	38,000	63,000	
Half band-width :				
(mμ)	98	94	105	
(10^{14} sec.$^{-1}$)	1·31	1·13	1·29	

(It should be noted that pH is always measured above 0° C., leaving one to surmise from this the hydrogen ion concentrations at − 20° and − 65° C. The fact that squid and octopus metarhodopsins exhibit the usual pH indicator properties at − 20° C. serves as something of an internal check on the pH of the system at that temperature. Another indication that the difference in hydrogen ion concentration between the acid and alkaline samples is maintained at least to some extent at the low temperatures is offered by the fact that acid or alkaline metarhodopsin, prepared above 0° C., maintains its identity upon lowering the temperature to − 20°, and − 65° C. (compare Fig. 3 of ref. 2 with Fig. 8 herewith).)

The absorption properties of the chromoproteins from squid and octopus, obtained from the types of experiment shown in Figs. 6 and 7, are summarized in Figs. 8 and 9, and in Table 2. The absorption spectrum of octopus alkaline metarhodopsin has not been included because it closely resembles that of the squid pigment.

Discussion. The absorption maximum of octopus rhodopsin lies at considerably shorter wave-lengths than that of squid rhodopsin, and this is even truer of the lumirhodopsins from the two species. Their metarhodopsins, however, are almost identical. The spectroscopic picture of the conversion of lumirhodopsin to acid metarhodopsin is therefore quite different with the two animals. In the squid, lumirhodopsin

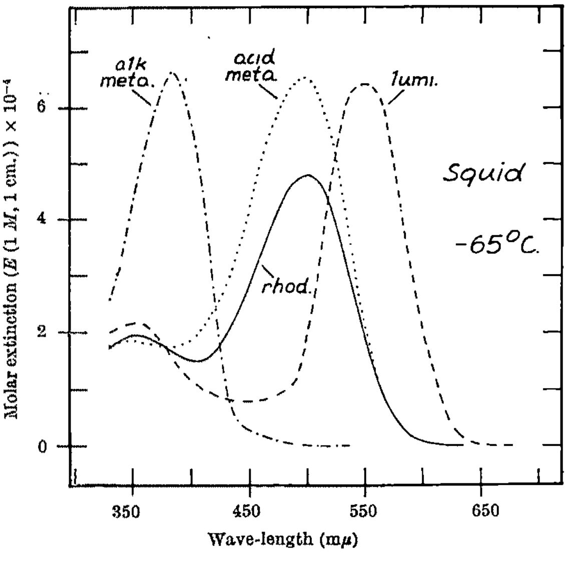

Fig. 8. Absorption spectra of squid chromoproteins in 2 : 1 glycerol–digitonin at − 65° C. The molar extinctions of rhodopsin and the two forms of metarhodopsin are derived from the extinction coefficients at + 5° C. (ref. 13), by cooling solutions of known extinction at that temperature to − 65° C., and correcting for volume shrinkage (3·7 per cent). The molar extinction of lumirhodopsin is obtained by measuring the extinction of rhodopsin which disappears when a given extinction of lumirhodopsin is formed (cf. Fig. 6). The spectrum of lumirhodopsin below 500 mμ is extrapolated by inserting the extinctions of alkaline metarhodopsin into the difference spectrum shown in Fig. 6. The results are averages from two experiments

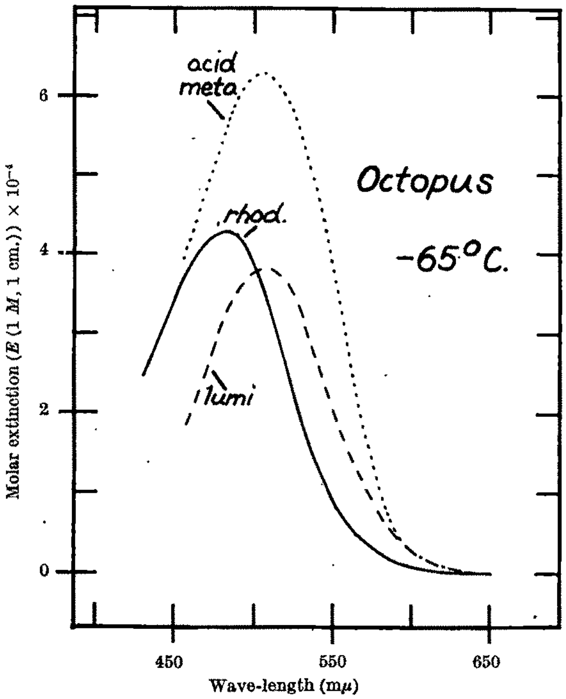

Fig. 9. Absorption spectra of octopus chromoproteins in 2 : 1 glycerol–digitonin at − 65° C. The molar extinction of rhodopsin at this temperature is obtained from that at + 2° C. (ref. 18) as described above. The absorption properties of lumirhodopsin are obtained from the type of experiment shown in Fig. 6, as described above. The absorption properties of acid metarhodopsin are derived from experiments like that shown in Fig. 7, by warming the solution containing acid metarhodopsin (Fig. 7, spectrum 3) to room temperature and raising the pH to about 9, to convert acid to alkaline metarhodopsin. The spectrum is then measured after re-cooling the solution to − 65° C., and the difference spectrum of acid metarhodopsin obtained in the same way as that of lumirhodopsin

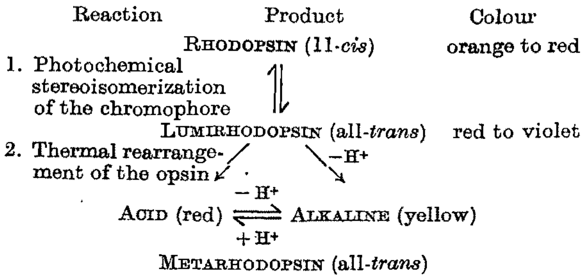
and acid metarhodopsin have almost the same extinctions, and the transformation involves primarily the relatively large shift of $\lambda_{\text{max.}}$ from 550 to 500 mμ. In the octopus, the situation is reversed: $\lambda_{\text{max.}}$ remains virtually unchanged, while $\varepsilon_{\text{max.}}$ increases from 38,000 to 63,000. A possible interpretation of such species differences is discussed in the first communication.

We have mentioned previously that irradiation converts vertebrate metarhodopsin to rhodopsin at − 20° C., but not at − 65° C. (first communication). This is true also of the cephalopod pigments, and can be seen particularly clearly in interconversions between rhodopsin and alkaline metarhodopsin, because of the wide separation of their absorption maxima. Irradiation of alkaline metarhodopsin at + 5° C. yields rhodopsin and isorhodopsin[13]. We find that the same occurs at − 20° C., and *not* at − 65° C. Just as with the vertebrate pigments, the interconversion of rhodopsin and metarhodopsin is blocked in *both* directions at − 65° C. We assume this to be due to a lack of mobility of opsin at that temperature (first communication).

The observations on cephalopod pigments are consistent with our previous view that the reaction, rhodopsin→lumirhodopsin, involves a change in configuration of the chromophore, whereas the reaction, lumirhodopsin→metarhodopsin involves a configurational rearrangement of opsin (first communication). The reactions initiated by the irradiation of cephalopod rhodopsins can therefore be summarized :



Reaction
Product
Colour
RHODOPSIN (11-*cis*)
orange to red
1. Photochemical stereoisomerization of the chromophore
LUMIRHODOPSIN (all-*trans*)
red to violet
2. Thermal rearrangement of the opsin
−H⁺
− H⁺
ACID (red)
ALKALINE (yellow)
+ H⁺
METARHODOPSIN (all-*trans*)

Since the cephalopod visual systems do not include the hydrolysis of metarhodopsin to retinene and opsin, visual excitation of these animals must be triggered by the conversion of rhodopsin to metarhodopsin, perhaps by the second phase of this process—the conversion of lumirhodopsin to metarhodopsin—which involves configurational changes in opsin (first communication). The present experiments show that in cephalopods the transformation of lumi- to meta-rhodopsin introduces pH indicator properties, owing to the possibility of dissociating a hydrogen ion from the metarhodopsin chromophore. The re-arrangement of opsin could involve further changes in charge, and it is possible that such changes are the sources of visual excitation.

Chicken Lumi- and Meta-iodopsin

By Dr. RUTH HUBBARD and Dr. ALLEN KROPF

THE first cone pigment was extracted from chicken retinas by Wald[22]. Although he was unable to purify and concentrate the visual pigment sufficiently to see its colour, he named it iodopsin on the basis of its absorption properties (*ion* = violet, Gr.). In the course of the present investigation, we have finally had a glimpse of pure iodopsin in sufficient concentration to confirm Wald's inference.

Like rhodopsin, iodopsin consists of neo-*b* (11-*cis*) retinene joined as chromophore to a colourless protein, an opsin[15]. The opsins of rhodopsin and iodopsin, however, differ substantially, and have been named rod opsin (or scotopsin) and cone opsin (or photopsin)[15]. The rhodopsin and iodopsin systems involve the same isomerization cycle of retinene: both photopigments are synthesized from neo-*b* retinene, and bleach in the light to all-*trans* retinene and the corresponding opsin[15].

As already noted[2,3] (see also first communication), the photochemical bleaching of rhodopsin involves a sequence of photochemical and thermal reactions, which yield as intermediates the two all-*trans* chromoproteins, lumi- and meta-rhodopsin. Using the same methods, we now find a similar sequence of reactions in the bleaching of iodopsin.

Light converts iodopsin to a first unstable product, which we call lumi-iodopsin. Above about − 45° C., this is converted in the dark to a second unstable product, meta-iodopsin. The latter hydrolyses in the dark above about − 30° C. to all-*trans* retinene and cone opsin. Furthermore, just as irradiation of lumi- or meta-rhodopsin converts it to rhodopsin by isomerizing its all-*trans* chromophore to the 11-*cis* configuration, irradiation of lumi- or meta-iodopsin re-isomerizes its all-*trans* chromophore to 11-*cis*, yielding iodopsin. A complete parallelism is seen therefore between the rhodopsin and iodopsin systems.

Experimental results. Before describing the interconversions of iodopsin with lumi- and meta-iodopsin

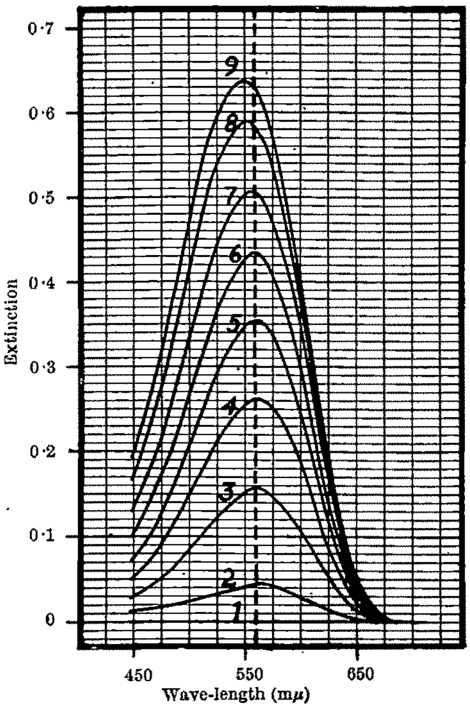


Fig. 10. Synthesis of iodopsin in aqueous 2 per cent digitonin (*p*H 6·1). The opsins (rod and cone) were extracted from light-adapted chicken retinas (ref. 15), and 0·2 ml. of the extract was balanced in the Cary recording spectrophotometer against another sample of the same solution as blank (spectrum 1). Successive portions of neo-*b* retinene (approximately 0·7 mμmol. in 0·005 ml. 1 per cent digitonin) were added, and spectra recorded 5 min. after each addition (spectra 2 to 9). Chicken cone opsin has a much greater affinity for neo-*b* retinene than rod opsin. The first five additions, therefore, resulted in the formation of iodopsin alone ($\lambda_{max.}$ 560 mμ; spectra 2–6). Further additions yielded progressively more rhodopsin ($\lambda_{max.}$ 503 mμ), as shown by the shift of $\lambda_{max.}$ toward shorter wave-lengths (spectra 7–9)

in more detail, we need to comment upon the preparation of iodopsin.

Chicken retinas contain both cones and rods, in the ratio[15] of about 8 : 1. Hence the extraction of photosensitive pigments from dark adapted retinas always yields mixtures of rhodopsin and iodopsin[15,22]. However, Wald *et al.* showed that one can obtain from light-adapted chicken retinas mixtures of the colourless rod and cone opsins, which upon incubation with neo-*b* retinene in solution yield rhodopsin and iodopsin[15]. They showed further that chicken cone opsin has a much greater affinity for neo-*b* retinene than rod opsin, so that the addition of limited amounts of neo-*b* retinene (less than needed to combine with all the available cone opsin) results in the formation of iodopsin alone, uncontaminated with rhodopsin.

We have used this method of preparation, as illustrated in Fig. 10. In the experiment shown, the first five additions of neo-*b* retinene resulted in the synthesis of iodopsin alone, with $\lambda_{max.}$ 560 mμ (curves 2–6). Further additions led to the formation of rhodopsin ($\lambda_{max.}$ 503 mμ), as shown by the shift of $\lambda_{max.}$ toward progressively shorter wave-lengths (curves 7–9).

For the experiments described below, the mixed opsins (rod and cone) from 200–250 chicken eyes were extracted by the methods of Wald *et al.*[15], and a small aliquot of each new preparation was assayed as shown in Fig. 10. The opsin stock was then mixed with less neo-*b* retinene than would saturate the cone opsin (for example, 3·5 mμ mole neo-*b* per 0·2 ml. of the opsin preparation shown in Fig. 10), and the resulting iodopsin solutions were stored frozen at − 15° C. For use, they were thawed and mixed with equal or double their volumes of glycerol, depending on the temperature at which experiments were conducted. (This way of preparing iodopsin has the manipulative advantage of letting one work in white light until the retinene is added; only then need one shift to the dim red light required to avoid bleaching iodopsin[15,22].)

Fig. 11 shows the results of irradiating such an iodopsin preparation at − 20° C. (spectrum 1) with orange light. This converts it almost completely to meta-iodopsin, with $\lambda_{max.}$ about 500 mμ (spectrum 2). Meta-iodopsin is stable below about − 35° C., but even at temperatures as low as − 20° C. it hydrolyses slowly in the dark to all-*trans* retinene and opsin. The hydrolysis is speeded at higher temperatures. The sample shown in Fig. 11 had for this reason been brought to room temperature before measuring spectrum 3.

Since the absorption spectra of iodopsin and meta-iodopsin overlap only slightly, at appropriate wave-lengths one can irradiate the one with almost no effect upon the other. As shown in Fig. 11, irradiation at 610 mμ results in a virtually quantitative conversion of iodopsin to meta-iodopsin. Conversely, by irradiation at 450 mμ, one can convert a considerable fraction of meta-iodopsin back to iodopsin, as shown in Fig. 12. Moreover, this wide separation of the absorption maxima of iodopsin and meta-iodopsin enables one to identify them, when mixed, more easily than the vertebrate rhodopsins and meta-rhodopsins produced in comparable experiments (cf. refs. 2 and 3). Otherwise, these experiments raise no new issues that have not already been discussed for rhodopsin[2,3,13] (see also first and second communications).

When iodopsin is irradiated at lower temperatures than those used in the experiments of Figs. 11 and 12, it is converted only to lumi-iodopsin. This must be warmed above about − 45° C. before it changes to meta-iodopsin. The absorption spectrum of chicken lumi-iodopsin has the same shape as those of the other chromoproteins we have described (first and second communications), and its $\lambda_{max.}$ lies at about

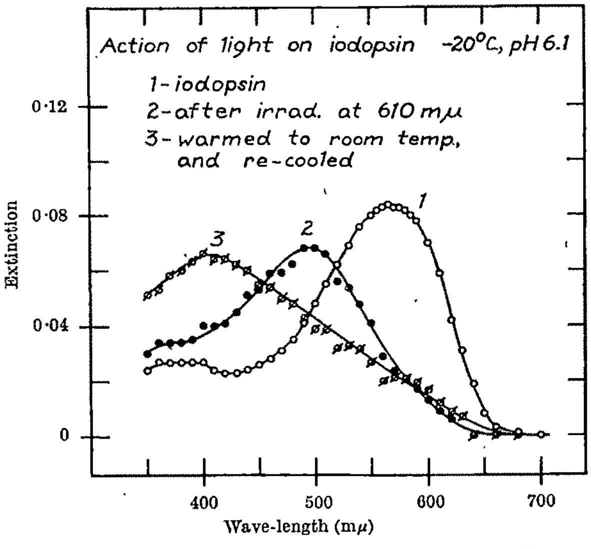

Fig. 11. Formation of meta-iodopsin, and its hydrolysis to retinene and opsin. Iodopsin in 1 : 1 glycerol–digitonin (*p*H 6·1) is cooled to − 20° C. (spectrum 1), and irradiated 20 min. at 610 mμ (half band-width 6 mμ). This converts almost all of it to meta-iodopsin, with $\lambda_{max.}$ about 500 mμ (spectrum 2). Upon warming to room temperature in the dark, the latter hydrolyses to retinene and opsin (spectrum 3)

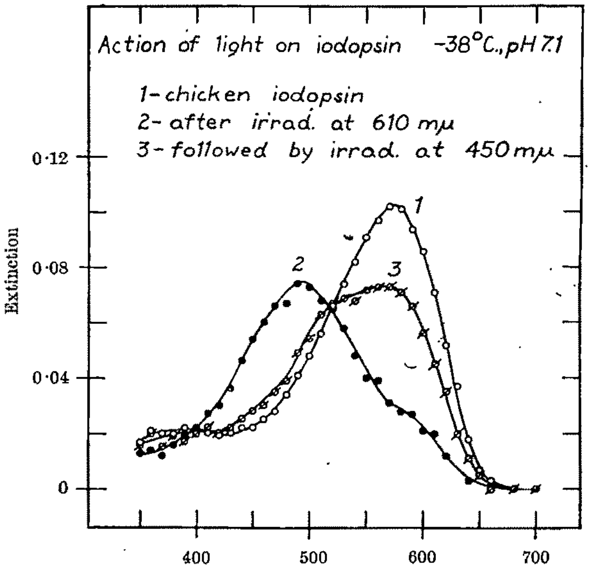

Fig. 12. Interconversions of iodopsin and meta-iodopsin. Iodopsin in 2 : 1 glycerol–digitonin (*p*H 7·1) is cooled to – 38° C. (spectrum 1) and irradiated 2 hr. at 610 mμ (16 mμ half band-width). This results in its partial conversion to meta-iodopsin (spectrum 2). The latter is now irradiated 20 min. at 450 mμ (same band-width), which converts a large fraction of it back to iodopsin (spectrum 3). Neither irradiation is sufficiently extensive to produce the steady-state mixture of chromoproteins (refs. 2 and 3). In this experiment, the temperature of the Beckman cell compartment was controlled (first communication) by circulating butyl 'Cellosolve' from a reservoir chilled with solid carbon dioxide

525 mμ. The isomeric 9-*cis* chromoprotein, isoiodopsin[15], on irradiation yields the same lumi- and meta-iodopsins as does iodopsin (cf. refs. 2 and 3).

We have made the surprising observation that the photosensitivity of iodopsin, that is, the quantum yield of photoisomerization from 11-*cis* to *trans*[2,3], decreases markedly as one lowers the temperature. (Compare, for example, the extent of conversion of iodopsin to meta-iodopsin in the experiment of Fig. 11, in which the irradiation lasted 20 min., with that shown in Fig. 12, in which the same type of irradiation was continued for 2 hr. at a higher intensity.) It is difficult to formulate this observation quantitatively, since the irradiation yields different products as one lowers the temperature. However, irradiating always at 610 mμ, and making approximate allowance for differences in the absorption spectra of the products—retinene, meta-iodopsin, and lumi-iodopsin—the effect is unmistakable. We have observed that the photosensitivity of the conversion of squid rhodopsin to alkaline metarhodopsin also decreases between + 5° and – 20° C., though the effect is considerably smaller than with iodopsin. However, we observe essentially no decrease in quantum efficiency when photoisomerizing neo-*b* retinene in the same solvent system (2 : 1 glycerol-digitonin) at + 20° and – 40° C. The decrease in photosensitivity on lowering the temperature therefore appears to be associated with the coupling of neo-*b* retinene as chromophore to opsin, particularly to cone opsin.

Discussion. The bleaching of rhodopsin and iodopsin by light proceeds over intermediates with similar chemical and spectroscopic properties (lumi- and meta-pigments) and results finally in the release of all-*trans* retinene and opsin. It is reasonable to assume that the photochemical and thermal reactions involve the same type of change in both classes of pigment—that in both the photochemical isomerization of the *cis* chromophore to the all-*trans* configuration is followed first by the thermal re-arrangement of opsin, then by the hydrolytic cleavage of the all-*trans* chromophore from opsin.

We have postulated that the configurational re-arrangement of the opsins from the lumi- to the meta-pigments is blocked at low temperatures by their structural rigidity and that of the solvent. It is tempting to speculate that this rigidity of the opsins also imposes configurational barriers which restrain the photoisomerization of the chromophore, and thus are responsible for the observed decrease in photosensitivity.

By analogy with the schemes proposed for the action of light on rhodopsins (first and second communications), we can summarize our observations with chicken iodopsin as follows :

Reaction	Product	Colour
	IODOPSIN (11-*cis*)	violet
1. Photochemical stereoisomerization of the chromophore	⇅	
	LUMI-IODOPSIN (all-*trans*)	purple
2. Thermal rearrangement of the opsin	↓	
	META-IODOPSIN (all-*trans*)	red
3. Hydrolysis of the chromophore from opsin	↓	
	RETINENE (all-*trans*) + OPSIN	yellow

The absorption maximum of chicken iodopsin lies at a considerably longer wave-length than those of the rhodopsins. We assume that this is due to stronger interactions (owing in part, perhaps, to a closer steric fit) between the neo-*b* chromophore and cone as compared with rod opsin[9]. The absorption properties of lumi- and meta-iodopsin, on the other hand, are not very different from those of the corresponding rod chromoproteins (first and second communications). This suggests that photoisomerization of the retinene chromophore to the all-*trans* configuration tends to equalize the degree of its interaction with rod and cone opsin.

GEOPHYSICS, ASTRONOMY and METEOROLOGY

Cosmic Radiation and the Weather

THE purpose of this communication is to point out the existence of a large tropospheric and stratospheric effect produced by the solar-cycle modulation of cosmic rays. Since there is some evidence for solar-cycle correlations in the weather, the phenomena described here should be considered in attempts to understand climatological effects of solar-cycle period.

The records of Forbush[1] for the ionization produced by cosmic rays at the ground show through two solar cycles in inverse correlation with solar activity; that is, if one compares sunspot numbers with cosmic-ray ionization at sea-level, it is found that high sunspot numbers are associated with low cosmic-ray ionization (see Fig. 1). Neher and Winckler[2,3] have shown that ion chambers at the top of the atmosphere show a very much larger modulation with the solar cycle than the instruments at sea-level. The change in ionization at 10 mb. is bound to be approximately a 50 per cent reduction between sunspot minimum and sunspot maximum. That this change in ionization is produced by a true cosmic-ray modulation was demonstrated by the study of primary cosmic-ray alpha-particles by Freier, Ney and Fowler[4], who found that the change in the flux of primary helium nuclei with energy greater than 200 MeV./nucleon was 50 per cent at the top of the atmosphere, in quantitative agreement with the ionization measurements of Neher and Winckler. Because the solar-cycle modulation changes the flux of low-energy particles more than the flux of high-energy particles, the change in the atmosphere due to ionization must show a latitude effect. (This effect is produced by the selective effect of the Earth's magnetic field on primary cosmic rays. For example, at the equator, in the vertical direction, only cosmic-ray protons of energy greater than 15 BeV. can reach the Earth, whereas at the magnetic poles cosmic rays of all energies can arrive.) The relation between cosmic-ray flux and atmospheric ionization is quite well understood, and it is therefore possible to construct a graph showing the percentage change in atmospheric ionization as a function of altitude and latitude. In order to do this, one combines the results of sea-level ion chambers and the balloon observations to give a profile of the ionization through the atmosphere.

Fig. 2 shows the result of using the cosmic-ray observations to determine the percentage change in world-wide ionization. The percentages plotted show the amount by which the ionization was reduced from 1954 (sunspot minimum) to 1957 (sunspot maximum). Note that the latitudes plotted are geomagnetic rather than geographic. The percentages are $\frac{I_{1954}-I_{1957}}{I_{1954}}\times$ 100, where I_{1954} represents the ionization in 1954, and I_{1957} that in 1957.

It can be seen from Fig. 2 that even in the troposphere a relatively large percentage change in the ionization occurs. If there is a connexion between atmospheric ionization and thunderstorm activity, for example, the solar-cycle modulation might be observed in the climatological data. A relation between ionization and weather

has been previously postulated by Vonnegut. The known variations of cosmic rays may allow a test of such a hypothesis. In looking for climatological variations, a further point should be made about the cosmic-ray data. The two solar cycles measured so far show that the largest changes occur during one or two years near sunspot maximum. Because solar activity rises relatively rapidly from sunspot minimum to sunspot maximum, differences produced by ionization should be great between 1954, 1955 (sunspot minimum) and 1957 (sunspot maximum). In looking for correlations over long periods of time, the most easily available index of the cosmic-ray ionization is the sea-level ion-chamber data at the equator (Huancayo), and the high-latitude ionization and neutron measurements of Fenton and Rose[5]. This should be one variable in any correlation study of this problem.

The cosmic-ray changes observed by Forbush and the calculated changes in ionization rest on firm ground. It is perhaps worth speculating on the kind of climatological effects the change in ionization might produce. It should be pointed out, however, that what follows is speculation and is included here only to suggest possible climatological variables to study.

If one assumes a connexion between ionization and storminess, for example, one might also expect a correlation of Earth temperature and the sunspot cycle. It seems reasonable to postulate that a lowered conductivity of the air (making it a better insulator) might enhance the build-up of electric fields and thereby increase storminess (at least thunderstorms). The increased cloud cover associated with the storms would produce radiation cooling of the Earth and a lower mean temperature at sunspot maximum. One might therefore account qualitatively for Humphrey's paradox of the 'hot sun and the cool Earth'. The suggested chain of events is shown diagrammatically above in Fig. 3.

The heavy connecting arrows show the established relations (1) and (2). The question mark on step (3) shows the speculative connexion between ionization and storminess. Relation (4) is also shown with a question mark, because it does not rest on firm observational grounds as do (1) and (2).

Obviously the chain of events suggested is just an example, and climatologists should be able to construct many such possible patterns which could be tested against the cosmic ray-variation of weather hypothesis.

In summary, it should be emphasized that the meteorological variable subject to the largest solar-cycle modulation in the denser layers of the atmosphere (that is, at pressures greater than 1 mb.) is the atmospheric ionization produced by cosmic rays. It seems, therefore, worth while to investigate the possible effects of the change in this variable in climatology.

Measurement of Horizontal Displacement along Faults in the Ocean Floor

IN the eastern Pacific Ocean a right lateral displacement of 84 nautical miles along the Murray Fracture Zone[1] has been suggested by a total magnetic intensity survey[2,3]. The Pioneer Ridge, a newly found east–west fault located between the Mendocino and the Murray Fractures along 38° 30′ north latitude and known to extend between 127° and 136° west longitude, was surveyed by the R.V. *Horizon* of the Scripps Institution of Oceanography of the University of California for the express purpose of measuring the direction and the amount of horizontal slip. A left lateral displacement of 138 nautical miles was found.

The method of measurement depends on the fortunate fact that the magnetic anomaly pattern of the ocean floor revealed by surveys which extend from 32° to 41½° N. lat. and from 125° to 135° W. long., is characterized by north–south trending features with a relief of several milligauss. The two lower curves in Fig. 1 are 15 miles apart and show the north–south alignment of the magnetic pattern. The east–west fractures cut across this pattern so that horizontal slip along a fracture produces a displacement. This is shown in Fig. 1 by a comparison of the uppermost profile taken north of Pioneer Ridge with the lower pair taken to the south. The uppermost profile is roughly 70 miles north and far to the west.

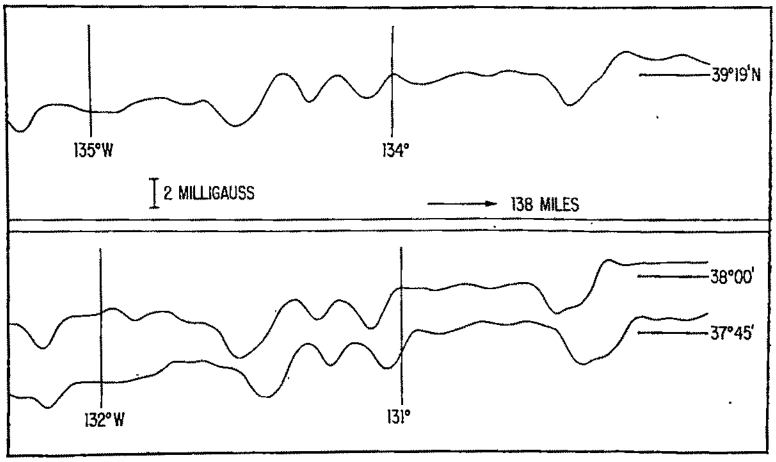

Fig. 1. Profiles of total magnetic intensity on both sides of, and parallel to, the Pioneer Ridge Fault, showing left lateral slip of 138 nautical miles

A left lateral fault with a displacement of 138 nautical miles is required to match the pattern. The goodness of fit shows that the amount of distortion accompanying this left lateral slip over a length of 90 miles was less than 10 per cent and implies a remarkable freedom of movement of one crustal block with respect to the other.

The measured displacements along the Murray Fracture Zone and the Pioneer Ridge reveal an unsuspected mobility of small blocks of oceanic crust.

Planetary Nebulæ in the Large Magellanic Cloud

PLANETARY nebulæ have been found in the Andromeda Nebula[1] and in the Small Magellanic Cloud[2]. A new catalogue of emission objects in the Small Cloud to be published shortly by me contains nearly six hundred objects; fifty-three of these are planetary nebulæ. Using the Armagh–Dunsink–Harvard telescope and prism with 103*a.E* red-sensitive plates exposed through a red filter, a planetary nebula is readily recognized by a single H_α emission line with no continuum and not associated with nebulosity.

This method has now been applied to the Large Magellanic Cloud. The observational programme is not quite completed and the plates taken have been only provisionally examined. Nearly one thousand emission objects have been found on these plates; at least 120 of these are planetary nebulæ. Where blue-sensitive prism plates are available and the objects are bright enough confirmation as planetaries is provided by the N_1 N_2 nebular lines of O III. The presence of planetary nebulæ presents additional evidence of Population II objects in the Large Cloud.

Rotational Structure of the 3914 A. N_2^+ Band in Sunlit Auroræ

ON the evenings of September 3 and 4, 1958, striking sunlit auroræ were observed from Saskatoon in the western sky. Although no photographs were taken, there can be no doubt about the nature of these displays because they showed the divided rays with greyish-coloured upper segments as described by Störmer[1], and because of the peculiarities of the spectrum. During each night of the display a plate was obtained with an *f*/0·8 Schmidt grating spectrograph having a dispersion of 40 A./mm., while a third plate was obtained from the displays of both nights with a large *f*/0·8 spectrograph having a dispersion of 20 A./mm. They were set to record the spectrum in the 3500–4500 A. region and the lines of sight of the instruments were directed towards the upper parts of the rays.

The lower dispersion spectra show unusually high relative intensities of the first negative N_2^+ bands for higher vibrational levels; this effect was first observed by Störmer and explained by Bates[2] as due to an abnormal distribution of the populations of the vibrational levels of N_2^+ resulting from the fluorescent excitation process dominant in sunlit auroræ. All three plates showed a most unusual intensity distribution in the fine structure of the 0,0 N_2^+ band at 3914 A. A microphotometer tracing of this band as photographed on the high dispersion plate is shown in Fig. 1*a*. For comparison a tracing is shown of the band from a normal aurora in Fig. 1*b*. The band from sunlit auroræ is developed to very high rotational quantum numbers, and its intensity distribution is not quite uniform from line to line. The lines of the *P* branch have crossed the zero gap and underlie the beginning of the *R* branch. The rotational temperature derived from the band by plotting log (I/K') against $K'(K' + 1)$ was 2,100° K. The perturbation at the line $R(38)$ is clearly visible.

There are two possible mechanisms which might explain the high rotational temperature. First, the N_2^+ ions might be in radiative equilibrium with the sunlight; this is an extension of Bates's explanation to cover rotational as well as vibrational degrees of freedom. Second, the N_2^+ ground-state might have a rotational distribution corresponding to thermal equilibrium at some high temperature, which might or might not be the temperature of the atmosphere at the height concerned. In either case, as was pointed out by Swings[3], the presence of Fraunhofer lines in the exciting sunlight would cause the distribution of line intensities to be non-uniform, just as in the spectra of comets[4,5]. The N_2^+ molecule, being homonuclear, has no rotation or vibration-rotation spectra, so that radiative equilibrium would be established easily if collisions were not important. If the first case is to be treated properly, absorption and emission in the *P* and *R* branches of all the bands of the system must be considered at once; for the second case only the absorption is important, but some of the higher bands may still contribute since the vibrational excitation is unusually high.

The exciting intensities were estimated from the Utrecht Atlas of the solar spectrum[6] as fractions of the continuum; the continuum was considered as having a colour temperature of 7,150° K. as recommended by Minnaert[7]. The first case was treated approximately by including the (0,0) and (0,1) bands which should be the most important; their shares of the excitation are in the ratio of about 3 : 1. For the second case only the (0,0) band was included. It would be expected that inclusion of more bands would tend to smooth out the distribution of intensities obtained. The general trend of the two sets of results was very similar, but there were considerable differences in detail and the second case gave better agreement with the observations. The temperature used was 2,100° K., as described above; the agreement of the calculated and observed spectra confirmed it.

We conclude that the N_2^+ ions observed had a rotational temperature in the ground-state of 2,100° K. There seems to be no way of deciding whether this is also the temperature of the atmosphere at the height observed, except perhaps from the fact that the ions do not seem to be in radiative equilibrium with the sunlight. It is conceivable that the high temperature

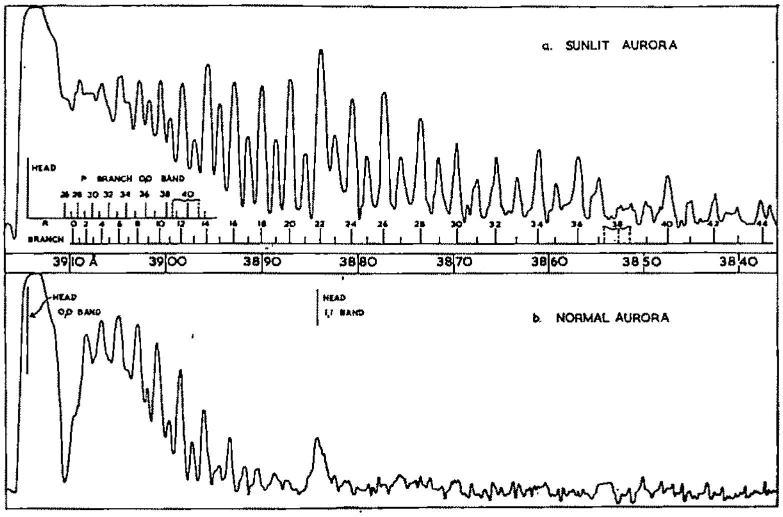

Fig. 1

could result from this mechanism, but that the distribution among the levels would be smoothed by collisions without lowering the temperature. This seems rather unlikely, especially if many of the collisions are with N_2, since charge-exchange can reduce the rotational temperature to the ambient in a single collision. It is at least possible that this observation shows a kinetic temperature of 2,100° K. at a height which is likely to be in the range 300–600 km.

The investigation reported here has been sponsored by the Geophysics Research Directorate of the U.S. Air Force, Cambridge Research Center, Air Research and Development Command, under contract 19(604)-1831.

Wear of Graphite Surface by Punching and Planing

The wearing process has been studied in detail on graphite basal plane surfaces rubbed by metallic micro-probes while being observed with a microscope having epi-illumination. When the graphite was smooth and flat, the probe under very light force could be passed repeatedly over the graphite without damage. Under increasing normal force, however, the surface showed a few sharp shadow lines extending away from the contact region, and these were interpreted as boundaries of stress or dislocation within the crystal.

Upon sustaining the contact pressure at a site showing such lines, by stopping the motion, it was found that the basal plane surface sometimes collapsed locally, in time-dependent manner. Instantaneously with the collapse the lines disappeared, and a tiny scar was found when the probe was moved away.

The scars were very shallow and in appearance resembled a hole in a skating rink with chips lying at the borders. It was evident that a graphite fragment had been punched out of a basal plane layer, and remained tilted against it if not completely pushed aside. When the probe was slid away from a scar, a wear track almost invariably began at the first pass and continued without diminishing.

These wear tracks were characteristically uniform in width and depth so that long straight lines of ruled geometry were easily drawn. The debris in the form of thin platelets was rather cleanly swept to the borders of a track and could sometimes be fitted back into it.

This type of wear was seen to occur through a planing of the basal plane surface. It appeared that the metallic probe itself could produce the wear track by penetration of the basal plane at the scar, or that the probe could trap a graphite fragment from the scar, which fragment then served as a secondary tool for the planing. It is easily imagined that the edges of such a fragment would tend to engage the opened edges of the scar so that a continuous wearing process would inevitably follow.

Wear by planing also started when the probe passed from smooth basal plane surface across a step (in the range 10^{-4}–10^{-5} cm. height), either upward or downward. In the first instance the basal plane was penetrated directly by passage of the probe against the riser of the step. In the second instance the probe usually produced a fragment by local collapse of the edge of the step under pressure at the descent. In both instances a continuous wearing process followed.

In these instances of wear by planing, the graphite surface was continuously delaminated by the tool. A characteristically different wearing process, also in the graphite basal plane, will be called 'peeling', and will be described in a later publication.

Metallic Conduction in the Crystal Compounds of Graphite

A marked increase of electrical conductance on forming crystal compounds of graphite with bromine, and even more with alkali metals such as potassium, has been previously attributed to electron transfer between the carbon hexagon networks, acting as amphoteric macro-aromatic molecules, and the intercalated atoms[1]. It was further suggested that the bonds between these macro-aromatic molecules and atoms such as potassium were metallic in character. Existing evidence indicated that electron transfer is less complete than when salts are formed with systems more strongly electro-negative than the carbon macromolecules (cf. also ref. 2). However, development of this interpretation has been hindered by the need to experiment with polycrystalline graphite, either as powder or in compacted forms[3].

Recently, we have been able to carry out experiments on pieces of graphite in which the preferred orientation of the carbon hexagon networks is so good that the results permit definite inferences about the behaviour of single crystals, and in particular about the anisotropy of the electronic properties along the *a*- and *c*-axes of graphite. By courtesy of the Morgan Crucible Co., pieces of 'columnar' graphite have been made available in which individual crystallites show excellent alignment of their *a*-axes parallel to the columnar axis, though their *c*-axes are disordered radially. By developing a method of depositing graphite by cracking methane[4], we have also had available pieces of graphite in which individual crystallites show excellent alignment of their *a*-axes parallel to a plane, and of the *c*-axes normal to it. Pieces of these materials several millimetres across in all dimensions have been mounted between 4-point platinum electrodes, so as to measure the electrical resistance parallel to the *a*-axis and parallel to the *c*-axis of the crystallites in the highly oriented material. Preliminary selection permitted the use of graphite with *a*-axis specific resistance as low as $3 \cdot 6 \times 10^{-5}$ ohm cm. (columnar natural graphite) and $4 \cdot 75 \times 10^{-5}$ ohm cm. (pyrolytic graphite). Furthermore, the specific resistivity in the *c*-axis of all samples of pyrolytic graphite was high, about 0·5 ohm cm. These values may be compared with previous direct determinations on very small single crystals[5]. A further test of the absence of serious crystal defects in the specimens now used was the measured temperature coefficient of resistance. With the best samples, this was always positive over the range 80–670° K. in the *a*-axis. In the *c*-axis direction of pyrolytic samples the temperature coefficient of resistance was negative.

It was found that because of the excellent alignment, these specimens could take up adducts such as bromine, iodine monochloride, or potassium, up to the limiting values characteristic of the most highly charged crystal compounds, without cracking due to uneven expansion of individual regions in the specimen. By suitable methods, practically all the adduct could be removed again, with recovery of the specimen. This could be treated in various cycles of crystal compound formation and decomposition while actually mounted in the jig used for resistance measurements.

Changes of conductance now found on forming crystal compounds of graphite can be referred to specific directions in the crystal. For compactness, *relative* changes *R*(crystal compound) / *R*(graphite) are recorded in Fig. 1. The values refer to room temperature but the temperature coefficients are small.

It will be seen that formation of the crystal compound leads to a marked decrease of resistance in the *a*-axis direction parallel to the planes of carbon hexagon networks. This accords with the previous interpretation that the conduction bands of the aromatic macro-molecules accept electrons from the potassium, and probably donate electrons to the bromine. However, the use of our highly oriented specimens of graphite permits the further conclusion that in this direction in the crystal the changes for the different crystal compounds are comparable in order of magnitude, with a reduction factor of about 10 in each case (Fig. 1).

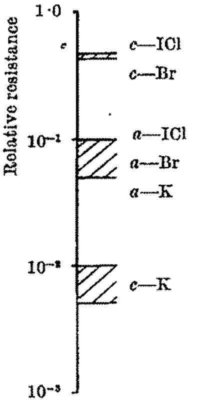

Fig. 1

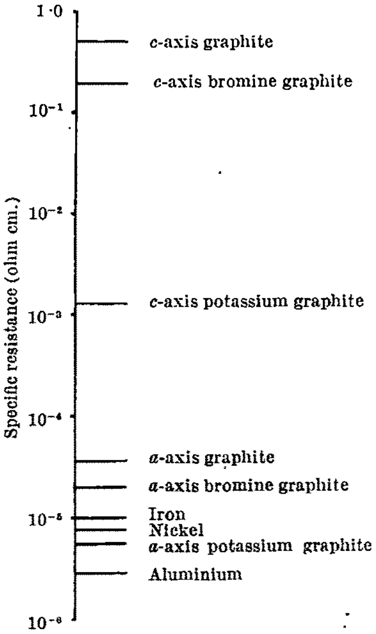

Fig. 2

Fig. 1. Relative change of resistance in *a*- and *c*-axis directions on forming crystal compounds of graphite

Fig. 2. Comparison of resistivity of well-aligned graphite and its crystal compounds with that of some metals

In the direction perpendicular to these networks, the decrease in resistance is even more striking. For the bromine and iodine monochloride adducts, only a small reduction factor (about 2) is observed. For potassium, on the other hand, the reduction factor is about 100–200. This relatively enormous increase in electrical conductance accords well with the view that the potassium atoms form 'quasi-metallic' bonds with the aromatic macromolecules in the crystals; these permit metallic conduction paths in the direction of the *c*-axis as well as those already present in the direction of the *a*-axis. The change to a more positive temperature coefficient lends further support to this view.

Tentatively, the much lower increase in *c*-axis conductance of graphite/bromine may be related with its different crystal structure. In potassium/graphite, C_8K (ref. 6), alkali metal atoms enter every layer and can thus form continuous metallic paths. In graphite/bromine, C_8Br, only alternate layers between the hexagon networks are occupied by the bromine (ref. 7). Thus, conduction paths are separated by a single Van der Waals repulsion distance from one another. This kind of solid conductor is comparatively novel electronically and may prove to exhibit other properties by means of which our tentative interpretation may be tested. For graphite/iodine monochloride it is not yet certain whether the adduct enters every layer or alternate layers[8]. The present resistivity would suggest that the structure is in fact similar to that of bromine/graphite.

It seems worth adding that the increases of conductance with the highly oriented specimens now available make potassium/graphite in the *a*-axis directions rather better than nickel as a conductor of electricity (Fig. 2). Other adduct atoms are being tested to see how far the nature of the adduct affects the increase of metallic conduction attainable; this may be expected to depend both on the adduct and the shape of the conduction bands in the parent material used.

We wish to acknowledge the support given by the Electricity Council to this research.

X-Ray Diffraction Measurement of Radiation Damage in Stretched Rubber

Bopp and Sisman[1] have mentioned that X-ray diffraction revealed a loss of crystallinity in a specimen of natural rubber irradiated to 10^7 r. in a reactor while stretched 300 per cent. During a study of radiation damage to elastomers, we have also observed the extreme sensitivity of stretched rubber to radiation.

5/32-in. sections of rubber specimens were stretched 500 per cent, exposed to a high irradiance of 1,000 kVp. X-rays until ruptured and periodically assessed for stress relaxation as manifested by diminished X-ray diffraction intensities.

An experimental mill-mixed rubber was used which was capable of sustaining a high stress without relaxation. Its composition, by weight, was as follows: deproteinized pale crepe, 100; sulphur, 2; zinc oxide, 3; zinc dibutyldithiocarbamate, 0·25; 2-mercaptobenzothiazole, 0·4. It was cured for 20 min. at 138° C. Specimens consisted of strips 10 mils thick and 1·3 in. wide, and were degassed *in vacuo*.

The stretched specimens were held by two Hoffman-type screw clamps mounted on a metal frame. They were firmly fixed by sandwiching between two aluminium plates, 1/16 in. thick, screwed to the frame. An aperture 1 cm. × 1 cm. in the plates exhibited the centres of the specimens for study.

Irradiations were carried out in an atmosphere of nitrogen with the General Electric Co. 'Resotron-1000' operated at 3 m.amp. and 1,000 kVp. Ferrous sulphate dosimetry showed an absorbed dose-rate of $2 \cdot 4 \times 10^5$ r./hr.

X-ray diffraction patterns were taken with the General Electric Co. *XRD*-3 Geiger-counter spectrometer. Instrumental conditions included a forward reflexion arrangement with the specimen aperture over the goniometer pivot, using copper $K\alpha$ radiation with a 3-deg. beam slit, Soller slit, 0·05-deg. detector slit scanning 2θ at 0·2 deg. per min., and nitrogen currents past both sides of the specimen.

When the specimens were arranged with the direction of stretch horizontal, the Geiger counter scanned the amorphous halo along the X-axis shown in the pre-irradiation pinhole diagram in Fig. 1. With the direction of stretch vertical, the counter scanned the diffraction spots and the halo between them along the Y-axis. An amorphous halo pattern was obtained by subtracting the spectrometer chart pattern for air-scatter from one for a specimen stretched in the horizontal direction. A diffraction spot pattern was obtained by subtracting a spectrometer chart pattern for a specimen stretched in the horizontal direction from the corresponding one for a vertical direction of stretch. The amorphous halo ran snugly between the diffraction spots of interest (Fig. 1) and added its outer shoulder intensities significantly to the intensities of the diffraction spots. The subtraction removed the influence of the amorphous halo and also the influence of air-scatter, since this was a constant factor. The diffraction spot pattern obtained by the subtraction represents the composite or 'average' of patterns produced by two rectangular areas of specimen, both having dimensions 5 mils × 375 mils and being centred in the sample-holder aperture with the long side vertical, since the defining aperture of the detector slit was vertical and had these dimensions. One specimen area was presented by a horizontal direction of stretch and had its long side perpendicular to the stretch, while the other area was presented by a vertical direction of stretch and had its long side

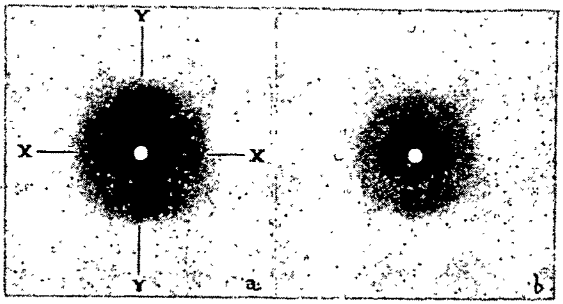

Fig. 1. X-ray diagrams of stretched rubber showing a loss of diffraction intensity upon irradiation: *a*, before irradiation; *b*, after $1 \cdot 85 \times 10^6$ r. absorbed dose

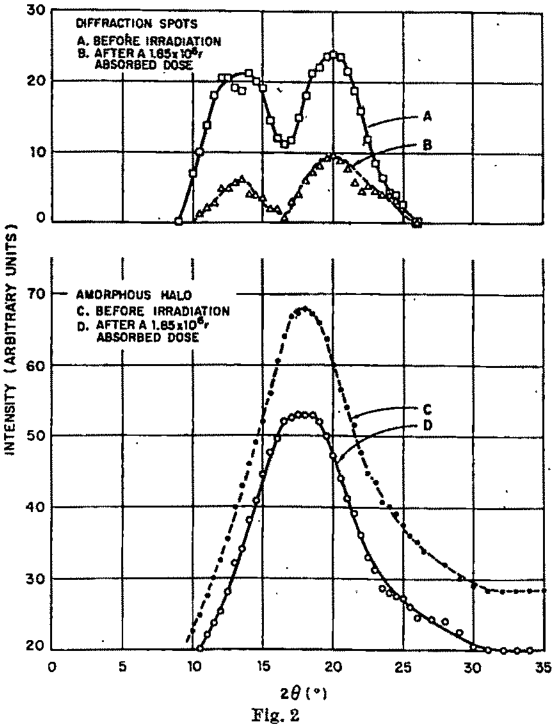

Fig. 2

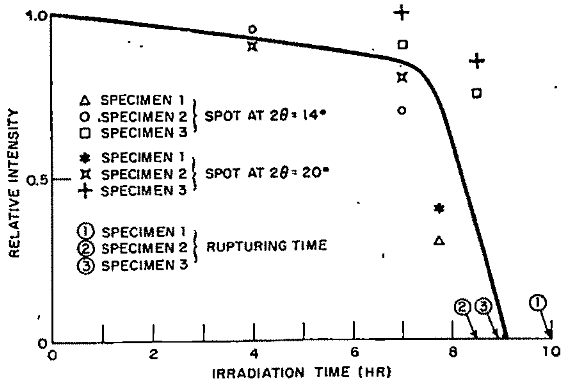

Fig. 3. Decrease in diffraction spot intensity (peak value) versus irradiation-time

parallel to the stretch. The halo intensities of these areas may have differed somewhat, and the diffraction spot pattern obtained by the subtraction is considered to be a semi-quantitative diffraction view of the specimen, useful for following and comparing radiation damage in rubber.

Stretched rubber is extremely sensitive to radiation damage, manifested by stress relaxation with attendant changes in X-ray diffraction intensity (Fig. 1) and early rupture. The average rupturing dose for three specimens was $2 \cdot 2 \times 10^6$ r.

Fig. 2 shows diffraction patterns for spots and halo for a specimen before irradiation and after a nearly rupturing dose of $1 \cdot 85 \times 10^6$ r. The changes suggest specimen thinning and conversion of some crystalline domain to amorphous. Diffraction intensity is extremely sensitive to thickness with very thin specimens of rubber. Hypothetically, if loss in spot intensity were due solely to thinning without any conversion of crystalline to amorphous domain, the spot and halo intensities would be decreased by the same percentage. If additionally an appreciable change from crystalline to amorphous domain occurred, the halo intensity would be reinforced appreciably, and the net result would be a percentage decrease in spot intensity greater than that of the halo. Fig. 2 displays this disparity.

Stress relaxation and attendant loss of diffraction spot intensity were detectable only after a significant lapse of time after initial irradiation. Fig. 3 shows the rate at which the maximum spot intensities decreased, and shows a detectable decrease after about 4 hr., which represents about 50 per cent of the rupturing dose.

It is believed that chain scission dictates the physical–mechanical radiation behaviour of stretched rubber. Stress relaxation would make scissions irreversible and their increase would soon weaken the specimen to the point when the chains slip and rupture of the specimen occurs. Cross-linking undoubtedly occurs simultaneously, but at too slow a rate to prevent destruction of the specimen. The extremely low doses which caused rupture in stretched specimens do not produce detectable physical–mechanical changes in unstretched rubber where cross-linking predominates.

CHEMISTRY

Behaviour of Dicobalt Octacarbonyl at Elevated Temperature and Carbon Monoxide Pressure

WHILE studying the dissociation of dicobalt octacarbonyl ($Co_2(CO)_8$), we found that at certain pressures and temperatures 1 mole of carbon monoxide was absorbed per mole of the compound. On increasing or lowering the temperature the absorbed carbon monoxide was given off.

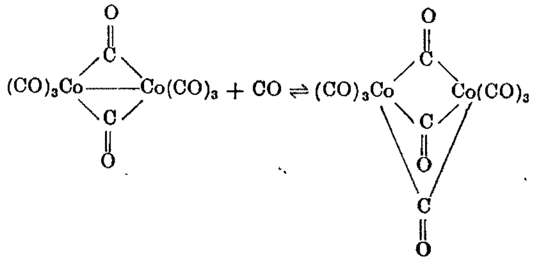
In a typical experiment, an autoclave provided with a heating mantle was charged with 77·4 gm. (226 m.mol.) of dicobalt octacarbonyl, the autoclave was pressured with carbon monoxide to 277·3 atm. at 28° C., and then was slowly heated to a certain temperature. To ensure equilibrium conditions, pressures were recorded only after temperature and pressure had remained constant for several hours. The differences between theoretical and observed pressure at various temperatures, expressed in moles of carbon monoxide absorbed per mole of dicobalt octacarbonyl, are given in Table 1.

Table 1

Moles of carbon monoxide absorbed per mole of dicobalt octacarbonyl	0·496	0·646	0·765	0·918	1·035	0·925
Temperature (° C.)	100	130	145	160	185	210
Observed pressure in atmospheres	342	362	373	378	393	425

The calculations are based on published compressibility data[1] and on the fact that the free space of the autoclave (after addition of dicobalt octacarbonyl) was 167 ml. The calibration of the pressure gauge permitted readings with an accuracy of ± 0·3 atm. After each reading the autoclave was allowed to cool to room temperature and the pressure then was recorded. The amount of carbon monoxide which remained absorbed at 28° C. and 272·2 atm. was found to be 0·095 mole of carbon monoxide per mole of dicobalt octacarbonyl.

It is unlikely, on the basis of molecular orbital considerations, that the uptake of carbon monoxide by dicobalt octacarbonyl is due to the formation of a dicobalt nonacarbonyl complex ($Co_2(CO)_9$):



Such a complex is structurally analogous to, but contains two more electrons than, iron enneacarbonyl ($Fe_2(CO)_9$). These two electrons would have to occupy the antibonding A_{1u} orbital[2] and thereby destabilize the complex.

A more plausible explanation of the uptake of carbon monoxide is to assume dissociation into a carbonyl cation and an anion:

$$CO + Co_2(CO)_8 \rightleftharpoons [Co(CO)_5]^+ + [Co(CO)_4]^-$$

In both ions cobalt has a stable rare-gas configuration. The dissociation of dicobalt octacarbonyl induced by carbon monoxide is entirely analogous to that induced by strong bases (B)[3,4]:

$$B + Co_2(CO)_8 \rightleftharpoons [BCo(CO)_4]^+ + [Co(CO)_4]^-$$

It is possible that other binuclear carbonyls such as manganese decacarbonyl ($Mn_2(CO)_{10}$) will behave similarly:

$$CO + Mn_2(CO)_{10} \rightleftharpoons [Mn(CO)_6]^+ + [Mn(CO)_5]^-$$

This finding may lead to a clearer understanding of the mechanism involved in certain reactions catalysed by metal carbonyls[4,5].

We wish to thank Prof. H. H. Jaffe of the University of Cincinnati for helpful discussions.

Polarography of Pentacyanocobaltate(III) Complexes

The cobalt(III) complexes of pentacyano-type, $[Co(CN)_5X]$, including several kinds of the new complex compounds, $K_3[Co(CN)_5Cl]$, $K_3[Co(CN)_5SCN]$, $K_3[Co(CN)_5N_3].2H_2O$, $K_3[Co(CN)_5NO_2]$ and $K_4[Co(CN)_5SO_3].2H_2O$, have been studied polarographically. The pentacyano complexes were found to be divisible into two groups from the point of view of their polarographic behaviour. The ions of one group, $[Co(CN_5Cl]^{3-}$, $[Co(CN)_5Br]^{3-}$, $[Co(CN)_5I]^{3-}$ and $[Co(CN)_5SCN]^{3-}$, were reduced irreversibly in two steps to cobalt(I) complexes, through the cobalt(II) state at the dropping mercury electrode in potassium halide supporting electrolyte (Table 1). The ratio of the height of the first wave to that of the second is approximately 1 : 1.

Table 1. The Half-wave Potentials of Halogeno- and Thiocyanato-pentacyano Complexes.

The concentration of the complex ions was 0·005 *F*, temperature, 25° C. The results for the halogeno complexes were obtained in the presence of 0·0032 per cent 'Tween-80', since all the second waves had the small maxima except in the case of the thiocyanato complex

Complex	$E_{1/2}$ of first wave Co(III) → Co(II) (V. vs. S.C.E.)	$E_{1/2}$ of second wave Co(II) → Co(I)	Supporting electrolyte
$K_3[Co(CN)_5Cl]$	−0·86 V.	−1·20 V.	3 *F* KCl
$K_3]Co(CN)_5Br]$	$-0{\cdot}71_5$	−1·18	3 *F* KBr
$K_3[Co(CN)_5I]$	−0·71	−1·13	3 *F* KI
$K_3[Co(CN)_5SCN]$	−0·78	$-1{\cdot}23_4$	1 *F* KCl

The ions of the other group, $[Co(CN)_5N_3]^{3-}$, $[Co(CN)_5S_2O_3]^{4-}$, $[Co(CN)_5NO_2]^{3-}$ and $[Co(CN)_5SO_3]^{4-}$, were reduced irreversibly in one step to cobalt(I) complexes (Table 2). The height of the wave for the ions of the latter group is almost equal to the total height of the waves for the ions of the former at the same concentration (Fig. 1).

The currents are completely controlled by diffusion with respect to all the pentacyano complexes. The diffusion current and the concentration of the complex ion are linearly related at the concentration in the range $10^{-2} \sim 5 \times 10^{-4}\,F$ (expressed as the 'formality', namely, the number of gram formula weights per litre of solution—cf. ref. 1).

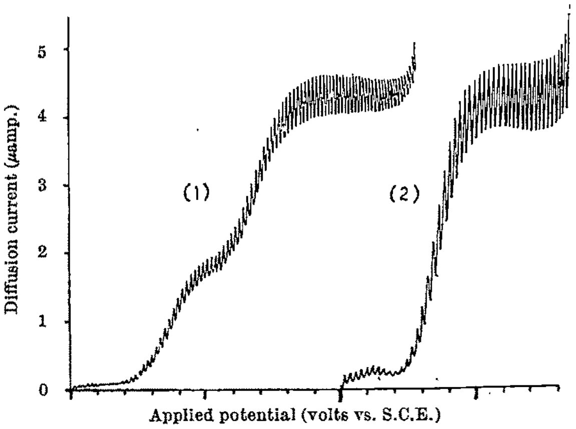

Fig. 1. Typical polarograms of pentacyano complexes obtained at the concentration of 0·001 *F*. Sensitivity: 1 : 80. (1) $[Co(CN)_5Cl]^{3-}$, in the presence of 0·0032 per cent 'Tween-80' (polyoxyethylene sorbitan mono-oleate). Supporting electrolyte: 3 *F* potassium chloride, from −0·5 V. (2) $[Co(CN)_5NO_2]^{3-}$, supporting electrolyte; 1 *F* potassium chloride, from −1·0 V. (versus S.C.E.), 100 mV./absc.

The half-wave potentials of the first waves for the ions of the former group are in the range $-0{\cdot}7 \sim -0{\cdot}9$ V. (versus the saturated calomel electrode), in potassium halide-supporting electrolyte, whereas those of the ions of the latter are in the range $-1{\cdot}2 \sim -1{\cdot}6$ V. (versus the saturated calomel electrode). On the other hand, for most of the usual cobalt(III) complexes, which are reduced to the metal through the cobalt(II) state, for example, ammine complexes, the half-wave potentials of the first waves are in the range +0·7 V. to −0·7 V. (versus the saturated calomel electrode)[2]. Thus the pentacyano complexes are very stable with respect to polarographic reduction. This is considered to be due to the stabilization of the complexes by the strong π-bond character in the bond between cobalt(III) and CN^-, that is to say, the co-ordinating bond is to be expressed by the formula $Co{=}C{=}N^-$ rather than by $Co{-}C{\equiv}N$. Accordingly, the stable existence of the oxidation state, + 1, in the polarographic reduction is not considered to belong only to the pentacyano complexes[3].

The polarographic stability of the pentacyano complexes increases in the following order of the ligand, *X*:

$$Cl^-, Br^-, I^-, SCN^- < N_3^- < S_2O_3^{2-} < NO_2^- < SO_3^{2-} < CN^-$$

As regards the reduction processes of the pentacyano complexes, they are believed to be as follows. For the ions of halogeno- and thiocyanato-complexes:

$$[Co(CN)_5X]^{3-} + e^- \rightarrow [Co(CN)_5X]^{4-} \qquad \text{1st step}$$
$$[Co(CN)_5X]^{4-} + e^- \rightarrow \text{Co(I) complex} \qquad \text{2nd step}$$

Table 2. The Half-wave Potentials of Azido-, Thiosulphato-, Nitro- and Sulphono-pentacyano Cobaltate(III) Complexes. Supporting electrolyte, 1 *F* potassium chloride; temperature, 25° C. The concentration of complex ions was 0·005 *F*.

Complex	$E_{1/2}$ of the wave, Co(III) → Co(I) (V. vs. S.C.E.)
$K_3[Co(CN)_5N_3).2H_2O$	$-1{\cdot}37_3$*
$K_4[Co(CN)_5S_2O_3]$	−1·29
$K_3[Co(CN)_5NO_2]$	$-1{\cdot}33_5$
$K_4[Co(CN)_5SO_3].2H_2O$	$-1{\cdot}53_5$
$K_3[Co(CN)_6]$	No reduction wave

* This result was obtained in the presence of 0·0064 per cent 'Tween-80'. The wave of the ion $[Co(CN)_5N_3]^{3-}$, which precedes that of the ion $[Co(CN)_5S_2O_3]^{4-}$, in the absence of the maximum suppressor, is shifted towards the negative direction of potential due to the presence of the maximum suppressor, 'Tween-80'.

For the ions of azido-, thiosulphato- nitro- and sulphono-complexes:

$$[Co(CN)_5X]^{(2+n)-} + 2e^- \rightarrow Co(I)\ complex$$

The structure and the co-ordination number of the cobalt(I) complex are not known at present, though efforts are now being made to isolate the complex in a solid state from the solution.

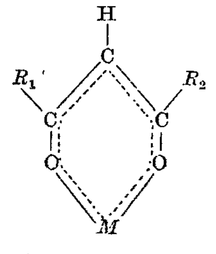
Metal – Oxygen Stretching Frequencies in the Metal Chelate Compounds of β-Diketones

RECENTLY, many papers[1] have been published on the infra-red spectra of metal chelate compounds of β-diketones in the sodium chloride (4,000 ~ 650 cm.$^{-1}$) region. The empirical assignments of the observed bands have also been made by Lecomte and other workers[2]. Since the CO stretching bands can be identified without much ambiguity, attempts have been made to correlate their frequencies with the stability of the chelates[3] or the ionization potential[4] of various metals.

It is expected, however, that the metal – oxygen stretching frequencies of these compounds are chemically most interesting since they are closely related to the stabilities of the chelates. Unfortunately, they are difficult to identify because they appear outside the sodium chloride region, and, furthermore, strong coupling with other modes may be involved.

We measured the spectra of thirty-two compounds of the following type in the 1,700 ~ 280 cm.$^{-1}$ region using optical components of sodium chloride, potassium bromide and cæsium bromide:



where, R_1, R_2 and M are variables. It was found that, in acetylacetonates and benzoylacetonates, the bands, ranging from 420 to 480 cm.$^{-1}$, shift to higher frequencies and increase in intensity as the metal is changed in the order (of stability): $Co^{2+} < Ni^{2+} < Cu^{2+} < Pd^{2+}$, as is shown in Table 1.

Table 1

	Acetylacetonates	Benzoylacetonates
Co^{2+}	420 cm.$^{-1}$	423 cm.$^{-1}$
Ni^{2+}	453	452
Cu^{2+}	455	458
Pd^{2+}	465	478
Al^{3+}	490	470

Also, in Cu^{2+} or Ni^{2+} chelates of various β-diketones, the same band shifts to higher frequency as R_1 and R_2 are changed in the order (of stability): CF_3, CF_3 < CF_3, CH_3 < CH_3, CH_3 < C_6H_5, CH_3 < C_6H_5, C_6H_5, as is shown in Table 2.

Table 2

R_1, R_2	Cu^{2+}	Ni^{2+}
CF_3, CF_3	——	——
CF_3, CH_3	445	427
CH_3, CH_3	455	453
C_6H_5, CH_3	458	453
C_6H_5, C_6H_5	463	460

These results seem to suggest that this band may be due to one of the metal – oxygen stretching modes or is at least closely related to it. In order to confirm this and to determine the coupling nature of this band, the normal co-ordinate treatment is necessary and will be carried out.

We wish to thank Prof. R. C. Lord, jun., of the Massachusetts Institute of Technology, for aid in obtaining the spectra in the cæsium – bromine region.

Existence of Two Liquid Phases in the System Cobalt Chloride–Water–Acetone

Katzin and Ferraro[1] have examined the composition of the solid phases and their equilibrium solutions in the system cobalt chloride–water–acetone at 25° C. During further studies of solutions containing these components it has been noticed that for certain water–acetone mixtures the addition of cobalt chloride can lead to a separation of two liquid phases.

Fig. 1 gives the relation of the region of immiscibility to the phase diagram given in ref. 1. The results were obtained by titrating aqueous cobalt chloride solutions, made from the recrystallized 'Analar' hexahydrate, with 'Analar' acetone, weighing both the portion of aqueous solution and the final mixture with acetone. A few points were obtained by preparing saturated solutions of the salt in known water–acetone mixtures, and titrating these with acetone or with water–acetone mixtures. The points in the present work were obtained at room temperatures of 20–21° C., whereas the saturation curve was determined at 25° C. A tie-line running through the centre of the immiscible region is also included in the phase diagram. It was obtained by analysing the two phases for cobalt and for water (by a Karl Fisher titration).

The immiscible area follows the saturation curve fairly closely, but a number of experiments have shown that at 25° C. there is a single liquid phase

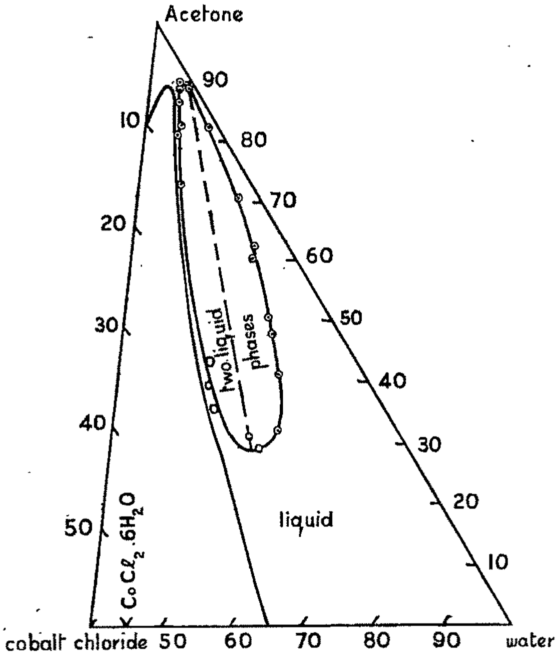

Fig. 1

at saturation. However, cooling to 20° C. may give two liquid phases in equilibrium with solid phase for solvent mixtures containing about 55 weight-per cent water, 45 per cent acetone. Single-liquid phases exclusively occur with compositions containing more than 90 per cent or less than 28 per cent acetone, and for mixtures containing less than 1 per cent of cobaltous chloride. It is interesting, as a phenomenon, that the addition of increasing amounts of cobalt chloride to a portion of, say, 50–50 water and acetone gives simple solution for a considerable concentration range; then there occurs a limited composition region in which there are two liquid phases, finally again a single liquid which remains so to saturation with solid. If the initial solvent mixture contains about 33 per cent acetone, the region of separation might appear as a minute region of turbidity only.

From the effect of temperature on some mixtures of fixed composition in sealed tubes it has been observed that the immiscible region expands as the temperature is raised. This expansion is most noticeable in the region of highest water concentrations, so that on raising the temperature we need progressively less acetone to produce a phase separation from a given cobalt chloride–water solution. The upper part of the immiscible region does not appear to be very sensitive to temperature changes.

For an over-all composition corresponding to a point near the middle of the region of phase separation, the phase rich in acetone is a light blue ($\lambda_{max.} \sim$ 672 mμ) and the phase rich in water is a deep magenta with two main regions of absorption ($\lambda_{max.} \sim$ 515 mμ, 664 mμ). These spectra correspond respectively to those for tetrahedrally co-ordinated $CoCl_2.2X$ (where X is a solvent molecule, in this case either water or acetone), and a mixture of this form with the octahedral species $Co(H_2O)_6^{2+}$, $CoCl_2.4X$, and intermediate stages.

It may be inferred that the presence of the two co-ordination states of the cobalt salt, with co-ordination four and six respectively, furnishes a mechanism for formation of two phases of different composition but with activities of the components equal. That is, the separation depends on the apparent fact that the tetrahedral form is preferentially soluble in the phase rich in acetone. The dependence of the phase separation on temperature can be understood since the equilibrium between octahedrally and tetrahedrally co-ordinated cobalt is known to move towards the tetrahedral form on raising the temperature. Other systems in which phases rich in acetone and in water are separated occur, for example, with salts such as potassium chloride and potassium fluoride, which are very soluble in the water and essentially completely insoluble in the acetone[3].

Rapid Quantitative Horizontal Paper Chromatography at an Elevated Temperature: Determination of Aspartic and Glutamic Acids

By the use of rectangular strips of filter paper, rather than filter paper disks, in combination with a horizontal solvent flow at an elevated temperature, amino-acids are rapidly separated as round compact spots rather than circular bands[1]. This is desirable since such spots in many cases lend themselves to quantitative study by the maximum colour-density technique. Recently, such a procedure has been applied to the analysis of tryptophan in an alkaline hydrolysate of α-casein[2].

This communication presents additional evidence to show that horizontal paper chromatography at an elevated temperature can be made quantitative by the maximum colour-density technique. A method is presented for the determination of aspartic and glutamic acids by direct photometry on paper chromatograms following two one-hour solvent developments at 60° C. in phenol saturated with *p*H 12·0 buffer[1].

For the glutamic acid assay, four standard amino-acid solutions (*p*H 6·5) containing, respectively, 0·100, 0·075, 0·050, and 0·025 μgm. of amino nitrogen are applied alternately to the paper in 0·5 μl. volumes at K_1, K_2, K_3, and K_4 (Fig. 1). The unknown solution is spotted at three concentrations (in 0·5-μl. volumes) to fall within the range 0·025–0·100 μgm. of the standard solutions. The aspartic acid analysis requires four standards in the range 0·075–0·150 μgm.

After colour development of the chromatogram[1], the maximum densities of the amino-acid spots are measured with a Denischron transmission densitometer (Model 3835*B*, W. M. Welch Scientific Company, Chicago, Ill.) using an aperture 1-mm. in diameter and the green filter built into the instrument. A standard curve is prepared by plotting the logarithm of the known concentrations against the densities.

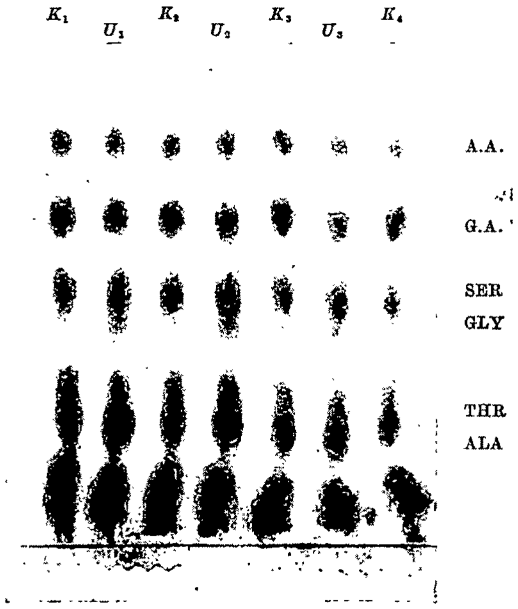

Fig. 1. A quantitative horizontal paper chromatogram of aspartic and glutamic acids after two 1-hr. solvent developments at 60° C. in phenol saturated with *p*H 12·0 buffer

Three 125-mgm. samples of an α-casein preparation[2] were hydrolysed for 24 hr. under reflux in 25 ml. solutions of 6 *N* hydrochloric acid. Following clarification of the hydrolysates as described previously[3], the dried residues were dissolved in 10 per cent *iso*propanol, filtered, adjusted to *p*H 6·5, and made up to a final volume of 25 ml. with 10 per cent *iso*propanol.

The determination of the content of aspartic and glutamic acids in α-casein gave values of 7·84 mgm. per 100 mgm. protein for aspartic acid and 20·43 mgm. for glutamic acid (Table 1). These values were in good agreement with 7·70 mgm. for aspartic acid and 21·02 mgm. for glutamic acid obtained using descending paper chromatography[4].

The accuracy and precision of the method was established by determining the aspartic and glutamic acid contents of a solution containing 40 mgm. of each of 18 common amino-acids per 100 ml. total volume, *p*H 6·5. A value of 39·0 mgm. (2·5 per cent deviation from the true value) was obtained for aspartic acid (Table 2) and 39·6 mgm. (1·0 per cent deviation) for glutamic acid. These values compared well with the values of 40·5 mgm. and 40·7 mgm. obtained for aspartic and glutamic acids using descending paper chromatography[5].

Table 1. THE ASPARTIC AND GLUTAMIC ACID CONTENT OF α-CASEIN AS DETERMINED BY HORIZONTAL PAPER CHROMATOGRAPHY

Chromatogram	Concentration found (mgm./100 mgm. α-casein) Aspartic acid	Glutamic acid

A New Sensitive Indicator for Semi-Micro Chelometric Titrations

RECENTLY, a new colorimetric reagent was introduced for the spectrophotometric determination of magnesium[1]. This reagent (LaMotte Chemical Products Co., Chestertown, Md.), 1-azo-2-hydroxy-3-(2.4-dimethylcarboxanilido)-naphthalene-1′-(2-hydroxybenzene), given the trivial name 'magon', has now been found to be useful as an indicator in the direct titrimetric determination of small amounts of magnesium.

There are several direct photometric methods for the determination of magnesium, of which titan yellow[2] and eriochrome black *T*[3] are examples. There is need for a direct titrimetric procedure for magnesium. Chelometric titrations employing ethylenediamine tetraacetate are widespread. These methods, as utilized for the determination of calcium and magnesium, include a titration of calcium and magnesium using eriochrome black *T* and a titration of calcium alone using murexide[4], zinchrome *R*[5], calcon[6] or other indicators. By the ethylenediamine tetraacetate method, magnesium is determined by difference between the two titrations. Errors encountered in either or both titrations affect the validity of the magnesium value. A direct value would be an improvement for the accurate titrimetric determination of small amounts of magnesium in the presence of large amounts of calcium.

This communication presents results of direct titrations of magnesium using the new, sensitive indicator magon. The indicator forms a coloured complex with small amounts of magnesium but not with small amounts of calcium. Magnesium in the complex is removed by titrating with ethylenediamine tetraacetate, resulting in a sharp colour-change of yellow-red to blue-violet to blue. The blue end-point is slower than the blue-violet but either colour-change can be used.

The results (Table 1) demonstrate that this indicator can be used in determining μgm. amounts of magnesium, recovery values being satisfactory. Metals such as copper and iron interfere by affecting the sharpness of the end-point. This difficulty may be alleviated by adding a small amount of solid potassium cyanide to the solution before adding the magon. The addition of a small amount of cyanide to the

Table 1. Direct Titrimetric Determination of Magnesium in Synthetic Solutions

* Procedure includes 10 ml. Clark and Lub's buffer *p*H 9·0, plus 15 ml. absolute methanol, plus 10 ml. magon (0·10 mgm./ml. MeOH). The solution is adjusted, if necessary, to *p*H 10·5 and then titrated with 0·005 *N* ethylenediamine tetraacetate.

† End-point fades, no cyanide present.

‡ 1–3 mgm. potassium cyanide added prior to addition of magon.

§ 1–3 mgm. ascorbic acid added prior to potassium cyanide.

solution should be made since large amounts slightly decrease the sensitivity of the colour-change. A buffer system, ammonium hydroxide–ammonium chloride, was unsatisfactory because of decreased sensitivity of the end point. Borate and tetraborate appear to increase a sharp colour change. Magon, essentially insoluble in water, is soluble in ethanol and methanol. Therefore the compound is dissolved in methanol and more methanol is added to the solution to be titrated. The concentration of alcohol in the solution to be titrated should range between 30 and 80 per cent. The indicator should be made fresh daily. Methanol is preferred since some decreased end-point sensitivity is encountered when using 95 per cent ethanol.

For this titration a *p*H-range of 9·0–11·0 is necessary. Clearest colour-changes are from *p*H 10·0 to 10·5. In the standardization of ethylenediamine tetraacetate with magnesium, the *p*H should be adjusted accurately to a selected *p*H within 10·0–10·5 and this same *p*H maintained for all titrations with the standardized titrant.

Under the above conditions the titration can be used for determining the combined amounts of calcium and magnesium, since calcium is titrated before magnesium. Calcium may be separated from magnesium as the precipitated calcium tungstate[7]. Preliminary results in this laboratory show magon to be very sensitive for the determination of total hardness of waters.

The possible usefulness of this new, sensitive indicator, or its magnesium complex, in the titration of micro-amounts of other metals should not be overlooked[8].

I wish to acknowledge the technical assistance of Neil Scott McNutt.

Validity of Clapeyron's Equation for Phase Equilibria involving Clathrates

Clathrates are solid solutions of a volatile solute in a host lattice[1]. The quinol clathrates studied by Powell[2] and the so-called gas hydrates[3] belong to this class of substances. Their host lattices, when empty, are thermodynamically unstable. In this respect they are different from the zeolites (Barrer[4]) in which the occluded component is sorbed in a stable host lattice. This has as a consequence that univariant phase equilibria involving a clathrate, in general, have no counterpart in the case of sorption in zeolites.

Consider, for example, a binary system water plus gas in which a clathrate (hydrate) occurs. The three-phase equilibria:

$$\text{ice} - \text{clathrate} - \text{gas} \qquad (1)$$

and

$$\text{aqueous solution} - \text{clathrate} - \text{gas} \qquad (2)$$

then are univariant ones in which the composition of the clathrate varies along the three-phase lines. The heat ΔH of decomposition of the clathrate into ice and gas (1), or into solution and gas (2), can be found from the slope of the three-phase line and the change in volume ΔV, according to Clapeyron's equation:

$$\frac{dP}{dT} = \frac{\Delta H}{T\Delta V} \qquad (3)$$

The values of ΔH per mole of solute thus obtained by earlier investigators and quoted by von Stackelberg[3] and Barrer and Stuart[5] are not invalidated by the fact that hydrates are solid solutions instead of stoicheiometric compounds. Equation (3) is a direct consequence of the second law of thermodynamics, and as such exact for all univariant equilibria, irrespective of the number of components.

Quite separate from Clapeyron's equation, one has a relation which determines the change in composition of the clathrate solution necessary to maintain equilibrium with ice in (1), or with an aqueous liquid in (2), when temperature or pressure are varied (compare, for example, equation (3.12) of ref. 1*a* and equation (15) of ref. 5). The latter relation is completely analogous to the well-known formula for the depression of the freezing point of ideal liquid solutions.

Clearly, equilibrium (1) is not analogous to the sorption equilibrium of a gas in a zeolite. The latter is a bivariant equilibrium to which Clapeyron's equation is not applicable, and for which the heat of desorption is proportional to the derivative $(\partial P/\partial T)$ at constant sorbed excess number of moles (cf. ref. 6, pp. 201–205, for an elegant treatment of this problem).

THERE is a difficulty which can occur regarding the interpretation of heats derived from Clapeyron's equation applied to phase equilibria involving clathrates. This difficulty is not thermodynamic in origin but arises from the non-stoicheiometry of the phases. Before this non-stoicheiometry was realized, heats evaluated using Clapeyron's equation were considered to refer to fully stoicheiometric reactions, for example:

$$CHCl_3 + 17H_2O \rightarrow CHCl_3.17H_2O \qquad (1)$$

the values 1 and 17 here being regarded as fixed integers. However, equation 1 should be formulated as:

$$xCHCl_3 + 17H_2O \rightarrow xCHCl_3.17H_2O \qquad (2)$$

where x is less than 1, has not a fixed value but may vary with P and T, was unknown to earlier experimenters and indeed in this and many analogous systems is still unknown. x could vary from one experimenter to another according to the physical conditions employed. The heats derived have therefore referred to uncompleted reaction equations and so have an uncertain meaning[1], until x is determined at the same time as the heat of reaction. Fortunately, x in many cases does not differ greatly from an integer, so that uncertainties resulting from non-stoicheiometry are not large.

BIOCHEMISTRY, PHYSIOLOGY and MEDICAL SCIENCES

Glucuronide and Sulphate Conjugation *in vivo* and *in vitro*

EARLY studies[1] of the metabolism of the polycyclic hydrocarbon 3:4 benzypyrene showed that this compound was converted within mouse and rat tissues to one or other of two water-soluble derivatives. These were characterized physically, but not chemically identified, and for convenience in later work were labelled as BpX_1 and BpX_2.

Later, Calcutt and Payne[2] showed that within mouse or rat liver—the major site of benzpyrene metabolism—BpX_1 was formed only in association with the heavy components of the soluble proteins representing the supernatant fraction of cell homogenates. On the other hand, BpX_2 was formed in the nuclei, mitochondria, microsomes and lighter components of the supernatant. The major site of formation of this derivative was the microsomes[3].

Harper[4] has now obtained evidence that BpX_1 is a mixture of the sulphuric acid conjugates of fully aromatic benzpyrenols, while BpX_2 is a mixture of the glucuronic acid conjugates of the same phenols.

It now becomes possible to correlate the above results concerning the primary metabolism of benzpyrene with other information in the literature dealing with *in vitro* systems of conjugation. It has been shown by Bernstein and McGilvery[5] and De Meio *et al.*[6] that sulphate conjugation *in vitro* is based upon an enzyme system present in the high-speed fraction of the supernatant from liver homogenate. Activity is dependent upon the presence of adenosine triphosphate and magnesium ions. The identification of the benzpyrene X_1 derivative as a mixture of sulphuric acid esters now gives an example of correspondence between *in vivo* and *in vitro* conjugation systems. In both cases sulphate conjugation has been found to be associated with the same cellular sub-fraction.

In the case of glucuronide synthesis *in vitro* activity has been found in the microsome fraction of liver homogenate[7,8] and to a lesser extent in nuclei and mitochondria[9]. With the recent proof that benzpyrene X_2 is a mixture of glucuronic acid conjugates we again have an exact parallel between *in vivo* and *in vitro* behaviour. In this case the parallel is not only with regard to the cellular sub-fractions concerned but also with the relative amounts of conjugate formed.

So far as we are aware this evidence, based on work with 3:4 benzpyrene, is the first example of known *in vitro* systems for glucuronic and sulphuric acid conjugation proving to be an accurate reflexion of behaviour in whole tissues under *in vivo* conditions. Furthermore, it is also apparent that the processes of homogenization and ultracentrifugation involved in the extraction of these enzyme systems for *in vitro* use do not result in the loss or redistribution of these systems.

Conjugated Forms of Urobilinoid Pigments

TAKASHI NORO[1] reported a fraction of urinary urobilinoids not extractable with chloroform but extractable by saponification with potash; this fraction he assumed to be in the ester form of the urobilinoids. We have found that some of the urinary urobilinoids not extractable with chloroform are characterized by their adherence to the gel-like precipitate formed during the extraction. Shaking normal urines, or preferably those from cases of hæmolytic jaundice, with Sevag's chloroform–amyl alcohol (9:1) mixture[2] results in partition of their urobilinoid contents. After centrifugation, part of the urobilinoids are found bound to the precipitate which collects at the interface and are extractable from it with ethyl acetate but not with chloroform, while the other part passes into the chloroform – amyl alcohol phase.

The paper chromatographic behaviour of these fractions was different. (Solvent: chloroform saturated with water–butanol–pyridine saturated with water (2·2 : 1·8 : 1); the urobilinoids were visualized by their green fluorescence in ultra-violet light after spraying with Schlesinger reagent.) The fraction extracted with chloroform migrated with the solvent front, but the bound urobilinoids behaved as a mixture of at least two compounds, the first of these remained at the start line, while the second moved slowly as an oblong spot behind the front. The first spot was readily stainable with protein dyes (for example, acid fuchsin) and by mucopolysaccharide staining procedures[3-5], thus showing its mucoprotein-bound character; the second spot was faintly stained by the latter procedure, and coloured brown by aniline hydrogen phthalate reagent[6] after heating, but was unstained by protein dyes, in accordance with the assumption that it is an oligo- (or mono-) saccharide-conjugated compound. The spot migrating with the front remained unstained by either procedure, which proved that it was free urobilinoid.

The mucoprotein-bound urobilinoids may be prepared separately from the oligo- (mono-) saccharide-conjugated urobilinoids by centrifugation of (*a*) the gel-like precipitate formed by extracting urines with ethyl acetate, or (*b*) of urines saturated with ammonium sulphate after adding 1·5 per cent butanol. This latter method (suggested by Heikel[7] for the preparation of directly reacting bilirubin from urine) yielded bound urobilinoid most abundantly. The mucoprotein-bound moiety can be lifted as a reddish-brown pellicle from the top of the aqueous phase; the oligo- (mono-) saccharide-conjugated urobilinoids pass into the ethyl acetate or butanol supernatant, respectively. The mucoprotein-bound urobilinoids seemed to behave, however, as a source of the oligo- (mono-) saccharide-conjugated pigments, which split off after incubation for 1 hr. at 37° C.; this decomposition was inhibited by 250 μgm./ml. heparin, but enhanced by 2 mgm./ml. trypsin. This splitting from mucoproteins occurred also during paper electrophoresis in Michaelis barbital buffer solution, *p*H 8·6, the oligo- (mono-) saccharide-linked urobilinoids leaving the mucoproteins and moving towards the anode-like free urobilinoids[8].

During electrophoresis in borate buffer (*p*H 8·6; 0·2 *M* H_3BO_3; 0·05 *M* $Na_2B_4O_7$), however, the oligo- (mono-) saccharide-conjugated and free urobilinoids behaved differently. Under these conditions carbohydrates have characteristic mobilities due to the formation of borate complexes, for example, glycuronic acid migrates 1·4 times as fast as dextrose[9]. Borate buffer electrophoresis of the supernatant formed after butanol has been added to urines precipitated by saturation with ammonium sulphate and centrifuged gave three urobilinoid bands, the fastest zone moving 1·4 times faster than dextrose. This zone and the middle one were coloured brown by spraying with aniline hydrogen phthalate and heating. The slowest zone behaved like free crystalline sterkobilin, and both were unstained by aniline hydrogen phthalate. The bands were cut out, extracted separately with the borate buffer described above, and the extracts were tested by Dische's carbazol reaction[10]. The fastest zone proved to contain glycuronic acid, while the slowest one did not.

Gray[11] expected work to be done on the conjugated urobilinoid pigments in urine; the above observations favour the assumption that besides free urobilinoids, urobilinoid glycuronide and another sugar-linked form, at present under investigation, may exist. Possibly these split from mucoprotein-urobilinoid compounds. These forms of urobilinoids were found to be more resistant to oxidation and decomposition during electrophoresis than free urobilinoids[12].

We are indebted to Prof. C. J. Watson for his gift of crystalline sterkobilin used in these experiments.

Patterns in the Amino-Acid Sequences of the Corticotropins

The complete amino-acid sequences of pig and sheep adrenocorticotropic hormone have been elucidated[1-3]. They have almost identical structures showing only minor variations in the C-terminal region. A striking similarity in pattern occurs in the acidic and basic portions of these proteins, although these regions are comprised for the most part of different amino-acids. This pattern becomes obvious when the amino-acid sequence 24–35 of the acidic portion is listed directly beneath sequence 12–23 of the basic portion. The actual sequences for amino-acids 12–35 are shown in Table 1*a* and *b* for the two proteins. Table 1*d* is a hypothetical sequence compiled from the best pattern correspondence in both. The other portions of both corticotropins, sequences 1–11 and 35–39, are identical.

—pro—	val—	gly—	lys—	lys—	arg—	arg—	pro—	val—	lys—	val—	tyr—
pro—	ala—	gly—	glu—	asp—	asp—	glu—	leu— —ser—	ala—	glu—	ala—	phe—
24	25	26	27	28	29	30	31	32	33	34	35

In the hypothetical sequence proline occurs at positions 12 and 24, glycine at positions 14 and 26, and aromatic amino-acids at positions 23 and 35. There is no correspondence at positions 19 and 31. The acidic amino-acids in the bottom chain are found in positions corresponding to those occupied by the basic amino-acids in the top chain, although there is no correlation between any one of the acidic (glutamic or aspartic) with any one of the basic (lysine or arginine) amino-acids. Similarly, valine on the top chain is replaced by alanine on the bottom. Each of the corticotropins differs from this hypothetical correspondence in pattern by a switch in the positions of two amino-acids in the acidic portion. In pig β-corticotropin, alanine exchanges position with aspartic, and in sheep α-corticotropin, alanine switches with serine. White and Landmann[4] have proposed a slightly different sequence (corticotropin-*A*) for the acidic portion of pig hormone that deviates from the hypothetical sequence only in that alanine in position 25 switches with glycine in position 26 (Table 1*c*).

The repetition of the pattern in the two regions suggests a duplication of the information template that confers the specificity. On a strict gene-template hypothesis having each amino-acid independently specified by a restricted region of the template, a remarkable series of mutations is required in the duplicate region such that the overall pattern is maintained but different amino-acids are specified. I prefer a scheme postulating two levels of information[5], one designating the pattern and the other determining which amino-acids will be incorporated into the pattern. Much of the biological specificity may reside in the pattern rather than in the individual amino-acids, since it has been shown that many major changes can be made in the chemical structure of peptides without affecting their biological specificity[6].

Distinction between Sodium and Potassium in Change in Permeability effected by Lipid-soluble Analogues of Acetylcholine

B. C. Abbott, A. V. Hill and J. V. Howarth have recently found that a rather strong positive heat roughly coinciding with the active phase follows within 100–300 msec. by a marked negative heat[1]. These results make untenable the assumption of a purely physical process underlying the bioelectric currents during nerve activity as proposed by Hodgkin and his associates. Further support for the necessity of a chemical reaction are the observations of Schoffeniels[2] with the isolated single electroplax of *Electrophorus electricus*: he found a Q_{10} of 3·6 for the action potential; the activation energy is 21,000 cal./mole.

A theory postulating a chemical reaction to be responsible for the change in permeability during conduction was suggested by Nachmansohn fifteen years ago. He proposed that the action of acetylcholine is an intracellular (or intramembranous) process essential for the generation of bioelectric currents. This view is based on a variety of physiological and biochemical features of the acetylcholine system which has the prerequisites for the postulated function, and on its relationships with electrical activity[3].

One of the principal objections to Nachmansohn's theory was the failure of acetylcholine to affect conduction when applied externally. This lack of effect has been explained by the failure of acetylcholine to reach the active sites, since it has been demonstrated that the ester does not penetrate to the inside of the cell[4,5]. Recently, however, a number of lipid-soluble analogues of acetylcholine were prepared. These compounds depolarize the axon in low concentrations and produce muscular contraction by direct action on the conducting membrane. The effects are rapid and, under appropriate conditions, reversible. In still unpublished experiments on isolated nodes of Ranvier, Staempfli and Dettbarn obtained depolarization with 10^{-6} *M* concentration (equivalent to 0·2 μgm. of acetylcholine per ml.). The question naturally occurs about the specific nature of this effect. Evidence in favour of a reaction with the acetylcholine receptor was obtained in experiments with eserine in which antagonistic actions between the alkaloid and the quaternary ammonium ion were found and their competitive nature was demonstrated[6,7].

The problem arises whether the lipid-soluble quaternary ammonium ions change the permeability in a way consistent with the assumption that their action opens the barrier specifically for Na^+, as postulated for acetylcholine, or whether the compounds produce an indiscriminate increase in permeability. This question is important since during activity Na^+ conductance specifically increases several hundred-fold; increase in K^+ conductance follows later and is relatively small. This question has been tested in the following way.

Desheathed tibialis nerve fibres of *Rana pipiens* were exposed to Ringer's solution containing the following lipid-soluble quaternary ammonium ions: noracetylcholine 12 and pyridinium dodecyl iodide (in 10^{-4} *M*) and pyridine aldoxime dodecyl iodide (in 10^{-5} *M*). At these concentrations no effect on the resting potential was observed. When the K^+ concentration in these solutions was raised to 20 m*M*, the depolarization which is usually observed was significantly reduced (about 20 per cent) both in respect to strength and in respect to speed of the response. In all experiments the response to the same K^+ concentration was tested prior to the addition of the quaternary ammonium ions. The results indicate a small but definite decrease of permeability to potassium.

The change to Na^+ permeability effected by these compounds was tested with concentrations five times as high, at which there is a pronounced depolarizing effect in normal Ringer's solution. When Na^+ was replaced by choline chloride, the depolarization was strongly reduced (by 30–50 per cent). On replacing again choline by Na^+, the original strength of depolarization was restored. Thus, the depolarization appears to be effected by a marked increase of permeability to Na^+. The selective change of permeability; small although significant decrease to K^+, marked increase for Na^+, appears pertinent in connexion with the assumption that the lipid-soluble analogues of acetylcholine mimic the physiological action postulated for the ester.

Depression in Percentage of Milk Fat by Parenteral Glucose Infusion and Glycerol Feeding

Low roughage - high concentrate diets can profoundly depress the fat content of milk[1-6]. One of us has advanced the hypothesis[6] that such depressions are the result of metabolic effects of an increase in the proportion of glycogenic to non-glycogenic products of digestion on such diets. Such an increase could be effected by a proportion of the starch escaping ruminal digestion, high ruminal lactic acid production, and an increased proportion of the glycogenic propionic acid in the products of ruminal digestion. There is evidence that low roughage - high concentrate diets have such effects[5,7,8]. It is also known that the proportions of fat and carbohydrate in the diet of animals can profoundly affect their carbohydrate and lipid metabolism, and changes, although erratic, in blood lipids have been recorded on low roughage diets[5,9], indicating some disturbance of lipid metabolism.

Experiments supporting the above hypothesis are now reported. Cows on normal hay concentrate diets giving milk with normal milk fat percentage were given continuous intravenous infusions of glucose over 48 hr. at the rate of 2 kgm. per 24 hr. and the fat percentage of the milk produced before, during and after the infusion determined. Oxytocin injections were used for obtaining as complete as possible evacuation of the udder at each milking. Normal feed consumption continued during the experiments. Results of a typical experiment are recorded in Fig. 1. Rate of milk production was maintained at quite a constant level during the infusion but fat percentage was rapidly depressed. Similar results were obtained when the concentrate allowance was decreased by an amount calculated to supply the same amount of net energy as the infused glucose.

Glycerol feeding, which would result in an increased proportion of glycogenic to non-glycogenic products of digestion due to high propionic acid production[10], was also found to depress milk fat percentage (Table 1) in agreement with the hypothesis. The glycerol was added to normal hay - concentrate diets, replacing an amount of concentrates calculated to supply the same amount of net energy.

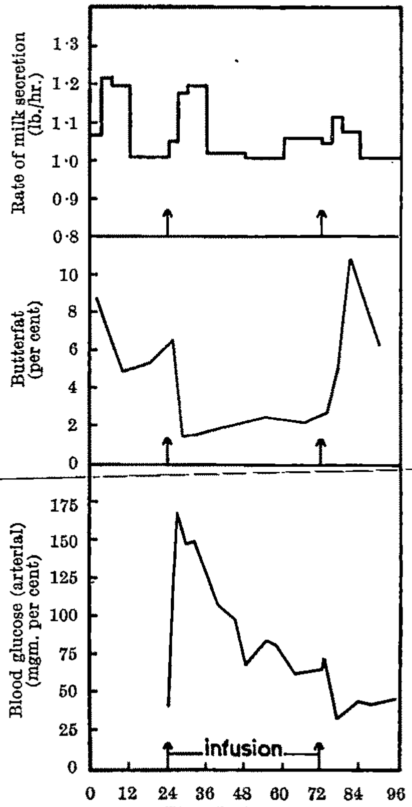

Fig. 1. Effect of intravenous infusion of glucose on the rate of secretion of milk, the butterfat test, and the level of blood glucose in a Jersey cow

It has been suggested that the fall in percentage of fat on low roughage - high concentrate diets is caused by lack of supply of acetate to the mammary gland, and acetate feeding has been reported to return depressed fat percentages to normal[3,4,11]. However, it has been shown that volatile fatty-acid levels in the blood and uptake by the mammary gland are not noticeably reduced on such diets[6]. Although it has yet to be demonstrated that the volatile acid in the blood is predominantly acetic as it is on normal diets[12], it seems likely that the positive results from acetate feeding are due to restoration of a more normal proportion of glycogenic to non-glycogenic products of digestion rather than to remedying an absolute lack of acetate.

Studies on the effect of the glucose infusions on blood lipid fractions are now in progress.

Grateful acknowledgment is made to the Commonwealth Bank of Australia for a grant from the Rural

Table 1. EFFECT OF GLYCEROL FEEDING (6 LB./COW/DAY) ON BUTTERFAT CONTENT OF MILK

Changes in the Secretion of 20α-Hydroxypregn-4-en-3-one by the Adrenal Gland of Young Calves

In a previous communication[1], we described the isolation of progesterone from the adrenal venous blood of cattle. During the course of this work it was observed that progesterone was sometimes accompanied by a more polar α,β-unsaturated ketosteroid in the young calf. Since changes in the nature of adrenocortical secretion have been observed during the early life of calves[2], it seemed appropriate to examine, first, the possibility of a relationship between progesterone and corticoid secretion; secondly, the relationship between the unknown steroid and progesterone; and thirdly, the chemical nature of the unknown steroid.

Adrenal venous blood was collected from 23 male and female Jersey and Guernsey calves, and the plasma was extracted in the manner previously described[1]. The results were not corrected for extraction losses, which were of the order of 40 per cent for progesterone; these losses would be slightly more for the unknown compound because of its greater polarity in the counter-current distribution system. In 10 animals the levels of cortisol and corticosterone were also determined in the adrenal venous plasma. For these estimations, the plasma, after treatment with 0·45 per cent sodium hydroxide, was extracted twice with an equal volume of ether followed by an equal volume of ethyl acetate. The dried residue from these extracts was acetylated with acetic anhydride labelled with carbon-14 in the presence of pyridine and carbon tetrachloride. The acetates so formed were separated on paper by the *B* system of Bush[3]. The areas of radioactivity corresponding to cortisol and corticosterone acetates were measured by the use of a windowless gas-flow Geiger–Müller counter coupled to a recording ratemeter. Recoveries of cortisol by this method were of the order of 70 per cent.

The unknown compound was found to have the same R_F value in a ligroin/80 per cent methanol paper chromatographic system as 20α-hydroxypregn-4-en-3-one, and the R_F values of the acetates of these two compounds were also identical. In addition, the unknown had an ultra-violet absorption maximum at 240 mμ characteristic of an α,β-unsaturated ketosteroid; after treatment with concentrated sulphuric acid[4], it gave an absorption maximum at 290 mμ, as did 20α-hydroxypregn-4-en-3-one. On oxidation with chromium trioxide[5], the unknown yielded a compound chromatographically indistinguishable from progesterone. On the basis of this information the unknown was therefore identified as 20α-hydroxypregn-4-en-3-one, and this has since been confirmed by a comparison of the infra-red spectra of the two compounds. The concentration of this steroid in the adrenal venous blood was always considerably in excess of the concentration found in peripheral blood, indicating that it was in fact secreted by the adrenal glands.

The secretion of 20α-hydroxypregn-4-en-3-one in comparatively large amounts by the adrenal gland continued under our conditions during the first 58 days of post-natal life, and between days 58–64 there was a change-over to the secretion of progesterone. This change was not associated with any alteration in the cortisol/corticosterone ratio (Table 1).

20α-Hydroxypregn-4-en-3-one has not hitherto been recognized as an adrenal steroid; however, it has been isolated from a number of other tissues in man[6], sheep[7] and rat[8], where it is generally regarded as a metabolite of progesterone. Its presence in the adrenal venous blood of calves was unexpected, since the 20β epimer is the major compound of this type present in adult cattle[9–11]. The only activity attributed to 20α-hydroxypregn-4-en-3-one so far is that of a weak progestational agent[6], and it is not yet possible to assess the significance of this 20-hydroxy compound in the adrenal secretion of the young calf.

Penicillin as an Antigen

THE ability of penicillin to function as an antigen, or more probably as a haptene, has only recently been described. Using the penicillin-sensitized red cell technique of Ley *et al.*[1], we have encountered eighteen sera from approximately 1,200 specimens, obtained from hospitalized patients, which have caused hæmagglutination. Preliminary testing was carried out on white porcelain tiles at room temperature using a 5·0 per cent suspension of group O, Rh-negative sensitized cells. Positive sera were titrated in 3 in. × ½ in. tubes at 37·0° C. and at 4·0° C. Control non-sensitized cells were included.

Subsequent investigation of the nature of the antibody involved in the reaction was mainly carried out on one serum which was arbitrarily scored as ++++ hæmagglutination by the tile method. Some characteristics of this serum are shown in Table 1.

Table 1

Hæmagglutinin titre (inactivated serum)	1/250
Hæmolysin titre (37·0° C. with complement)	1/64
Complement-fixation test (antigen–penicillin solution)	Positive fixation of complement
Heat stability of antibody	Withstands 56·0° C. for at least 6 hr.
*p*H range of hæmagglutination reaction	Active over range approximately 4·6–9·0

This patient had been receiving one mega unit of penicillin every 6 hr. for 4 weeks, and 7 days after cessation of therapy the hæmagglutinin titre rose to 1/1,000.

When a saline suspension of crystalline penicillin *G* was added in varying concentrations to varying dilutions of serum, an exponential-type curve was obtained when the reciprocals of the serum dilutions were plotted against the lowest concentrations of penicillin required to just inhibit hæmagglutination. The fact that proportionally higher concentrations of penicillin were needed to prevent hæmagglutination at the lower serum dilutions suggests that the antibody inhibition of penicillin is similar, in some respects, to that exerted by penicillinase.

The addition of penicillinase to penicillin-sensitized cells resulted in a considerable delay in the time required for hæmagglutination, but did not affect the final titres. This effect is apparently not due to destruction of penicillin adsorbed on to the cell surface since repeated washing of penicillinase-treated sensitized cells with 0·85 per cent saline restores fully the rate of subsequent agglutination by the serum.

Precipitin reactions both in tubes and by double diffusion techniques in agar gels have so far yielded negative results.

Our findings regarding the nature of this phenomenon differ in some respects from those described by Ley *et al.*[1]. These workers reported that certain sera gave positive hæmagglutination with the anti-globulin test. Repeated attempts with varying batches of anti-globulin sera have failed to substantiate this finding. In addition, direct Coombs's tests performed on the patient's own cells have also been negative, although the addition of penicillin solution to patient's washed cells results in agglutination indicating that antibody is apparently adsorbed on to the cell surface. These findings, however, appear to be explained by the results obtained from starch gel electrophoresis of the sera.

Attempts to characterize the antibody by conventional paper electrophoresis failed because it proved impossible to elute the antibody with saline from the paper. Ley *et al.*[1] were apparently able to elute antibody from sensitized cells by heating in saline at 54·0° C. for 15 min.; but we have been unable to confirm this observation. Starch gel electrophoresis according to the method of Smithies[2], however, proved a satisfactory procedure. After slicing the gels, one-half was stained with amido-black 10*B* for 30 sec. and cleared for approximately 10 min. in a mixture of methanol – distilled water – acetic acid (25 : 75 : 10 v/v). The high concentration of water prevented shrinkage of the gel for this period of time. The sliced portions of gel were matched, and fractions corresponding to the visualized separations in the stained half were cut from the unstained section. Each fraction was snap-frozen in dry ice and ether and then eluted with saline. The presence of antibody in each fraction was tested by the tube method. The starch remaining in the slots was examined by the same procedure. Antibody activity was consistently demonstrable in what Smithies[2] originally named pre-albumen$_1$ and pre-albumen$_2$. Pre-albumen$_2$ has now been identified as being acidic α_1-glyco-protein by Poulik and Smithies[3]. Pre-albumen$_1$ remains unidentified. In one patient difficulty was experienced in making all the antibody enter the gel and some activity remained in the slots. This patient, however, had a grossly abnormal protein pattern as a result of cirrhosis and secondary carcinomatous deposits in the liver. To be quite sure that antibody activity was associated with both fractions and not the result of trailing or irregular migration artefacts, the pre-albumen zone was differentiated by serial section and the titre of each fraction obtained was established. By this means two peaks of activity were demonstrated corresponding to the two pre-albumen zones. Control normal sera gave consistently negative results. It is stressed that the antibody has mobilities corresponding to the two pre-albumen zones, and may or may not be identical with these two fractions.

Further investigation of these sera is in progress, and it has been found that penicillin-sensitized bentonite particles can be substituted for red cells with satisfactory results.

Metabolism of Sulphobromophthalein

Despite the great sensitivity and widespread use of sulphobromophthalein (BSP) retention as an index of liver function, little is known of the actual function(s) involved in the hepatic uptake and excretion of the dye. Presumably, sulphobromophthalein is bound to proteins in the serum and is thus conveyed to the liver, where the pigment–protein complex is broken. On release it is excreted into the bile as the free dye[1]. We have found, however, that pigments of sulphobromophthalein appearing in the bile and other biological fluids are chromatographically different from the parent compound[2], suggesting that a chemical modification is involved in the clearance of sulphobromophthalein by the liver.

Sulphobromophthalein in human bile, urine or serum was extracted with 3 vol. of acetone. The extract was taken to dryness and subjected to paper chromatography in an ascending system, employing *t*-butanol/water (30 : 17·3 v/v). In bile, three pigments, arbitrarily designated as BSP–*A*, –*B* and –*C*, were distinguishable from free sulphobromophthalein (Fig. 1). Since incubation of sulphobromophthalein with bile at 37° C. for 24 hr. gave rise only to free sulphobromophthalein, these products were not the result of an extrahepatic complex formation in the bile.

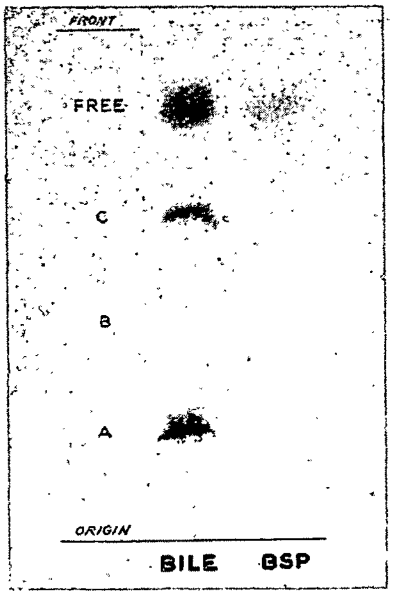

Fig. 1. Paper chromatogram of sulphobromophthalein pigments appearing in human bile

Based on their absorption at 575 mμ, the metabolites represented 65–75 per cent of the total sulphobromophthalein pigments appearing in human bile and urine, BSP–*A* usually being the most abundant. Only trace amounts of BSP–*A* and –*C* were obtained from serum. The metabolites have been similarly demonstrated in bile and urine from the rat, rabbit and dog.

Most of the proteins were removed during the acetone extraction, and the small amounts remaining were held at the origin during the chromatographic procedure. It is concluded, therefore, that the chemical differentiation between sulphobromophthalein and its metabolites is not dependent on protein.

To indicate that the production of sulphobromophthalein is a function of liver tissue, this substance was perfused through isolated liver from the rat. (We wish to thank Dr. G. L. Plaa and Dr. C. H. Hine for performing the perfusion phase of these experiments.) 90 per cent of the biliary sulphobromophthalein appeared as BSP–*A* and –*C*.

For further purification, sulphobromophthalein was extracted from bile or urine with acetone as above, dried and subjected to paper electrophoresis (Whatman 3 *MM* paper; 0·25 *M* acetic acid; 10 m.amp.; 1·5 hr.). The pigments (which move toward the anode) were eluted with water and the fractions of sulphobromophthalein were separated by chromatography in the *t*-butanol/water system. Each of the fractions was eluted with water and further purified by paper chromatography in an ascending system, using 5·2 parts *n*-butanol, 3·5 parts water and sufficient acetic acid to form a single-phase solution. Although these treatments nominally would be expected to result in a pure preparation, infra-red spectrographic observations indicated that significant impurities were still present.

The pigment characteristics of the purified BSP–*A* and –*C* were indistinguishable from those of the parent sulphobromophthalein; all three had identical absorption spectra in the visible range (single peak at 575 mμ) and identical curves when the absorption at 575 mμ was plotted against *p*H (indicator range was approximately 7·8–10·0).

The possibility that the metabolites are conjugates of sulphobromophthalein was investigated. BSP–*A* does not appear to be a glucuronide, since it is stable to hydrolysis with hydrochloric acid (0·2 *N*; 100° C.; 1 hr.), sodium hydroxide (0·2 *N*; 100° C.; 1 hr.) or with *B*-glucuronidase (*p*H 5·2; 37° C.; 25 hr.), and was negative for the presence of hexuronic acid when tested by the Dische reaction[3]. No hydroxamic acid was produced when the metabolite of sulphobromophthalein was treated with hydroxylamine reagent[4], suggesting the absence of an ester linkage in the molecule. Since ethereal sulphates are usually labile in hot dilute acid[5], it is unlikely that BSP–*A* is this type of conjugate.

Association of ninhydrin-positive material with the BSP–*A* fraction was consistently observed. A comparable chromatographic fraction from control bile or urine which contained no sulphobromophthalein was ninhydrin-negative. Rigorous hydrolysis with hydrochloric acid (6 *N*; 120° C.; 18 hr.) effected complete breakdown of BSP–*A*, yielding sulphobromophthalein, its decomposition products (moving with the front on paper), and a new substance(s) which was ninhydrin-positive and did not contain sulphobromophthalein. Final identification of the ninhydrin-positive compound(s) has been complicated by the appearance, after similar hydrolytic treatment, of ninhydrin-positive impurities in the comparable chromatographic fraction of the control bile or urine. Further purification to facilitate identification of these metabolites is being carried out.

Some of these results were presented before the Pacific Coast Section of the Society for Experimental Biology and Medicine, San Francisco, on February 20, 1957.

While this manuscript was in preparation, Krebs and Brauer[8], utilizing alumina columns, were also able to isolate unidentified metabolites of sulphobromophthalein from bile.

Anti-Thyroid Action of β-Aminoethyl*iso*thiouronium Dibromide in Rats

During the development of a screening test for goitrogenic activity of drugs, β-aminoethyl*iso*thiouronium dibromide, a radiation protective agent[1], was observed to have anti-thyroid activity. In view of possible long-term administration of this substance for prophylactic protection against irradiation, we are reporting our findings.

β-Aminoethyl*iso*thiouronium dibromide was prepared from ethylene imine and thiourea. 13·5 ml. ethylene imine (Chemirad Corp., Port Washington, New York) was dissolved in 80 ml. ether and the sediment removed. To this solution, chilled in a salt-ice bath, was added slowly a solution of 19·0 gm. thiourea and 57·8 ml. 48 per cent hydrobromic acid (s.g. 1·49) in 80 ml. methanol. After 6 hr., the precipitate of β-aminoethyl*iso*thiouronium dibromide which formed was removed and recrystallized three times from 80 per cent ethanol. The final product had a melting point of 194° C., corrected. Infra-red spectra of this material and authentic β-aminoethyl*iso*thiouronium dibromide obtained from Dr. D. G. Doherty were identical and a mixture melting point of the two was not depressed.

Female Sprague–Dawley rats weighing about 100 gm. were divided at random into six experimental groups of eight animals each and fed Rockland rat diet (1·20 mgm. iodide/100 gm. diet) *ad libitum*. The animals were given: (1) 400 mgm. β-aminoethyl*iso*thiouronium dibromide/kgm. body-wt./day; (2) 50 mgm. 6-propylthiouracil/kgm. body-wt./day; (3) 120γ L-thyroxine/kgm. body-wt./day; (4) 400 mgm. β-aminoethyl*iso*thiouronium dibromide + 120γ L-thyroxine/kgm. body-wt./day; and (5) 50 mgm. 6-propylthiouracil + 120γ L-thyroxine/kgm. body-wt./day by gavage daily as a freshly prepared suspension in 10 per cent gum acacia. A control group was given 10 per cent gum acacia alone. Daily weights were obtained. On the last day of drug administration, 0·05 μc. iodine-131 in 0·1 – 0·2 ml. solution was injected intraperitoneally. The animals were killed 24 hr. later, and the larynx with the thyroid gland attached was removed and assayed for radioactivity. The thyroid then was dissected carefully from the larynx and weighed.

The results are summarized in Table 1. The administration of β-aminoethyl*iso*thiouronium dibromide resulted in less iodine uptake and in some thyroid enlargement ($P < 0·05$). 6-propylthiouracil, which is known to be a powerful goitrogen, produced similar, though greater, changes. The increase in thyroid weight was prevented in both cases by the simultaneous administration of L-thyroxine. Thiourea derivatives are known to block the formation of thyroid hormone[2]. It is not surprising, therefore, that β-aminoethyl*iso*thiouronium dibromide, which is related structurally to these compounds, results in depression of iodine uptake and thyroid enlargement. While hypothyroid animals perhaps are somewhat more resistant to irradiation[3], the radiation protective action of β-aminoethyl*iso*thiouronium dibromide is greatest during the half-hour immediately following its administration, and in acute radiation experiments it is not likely that the anti-thyroid action of β-aminoethyl*iso*thiouronium dibromide explains any radiation protective action. However, it is of interest that cysteamine, another radiation protective compound, also has anti-thyroid activity[4].

Table 1. Effect of β-Aminoethyl*iso*thiouronium Dibromide (AET) and Propylthiouracil (PTU) on the Iodine Uptake and Thyroid Weight of Rats

Drug and dosage (10 days)	Average body-weights		Thyroid weight (mgm./100 gm. body-weight)	24-hr. radioiodine uptake (per cent)
	Initial (gm.)	Final (gm.)		
400 mgm. AET/kgm. daily	140	180	9·56 ± 1·0	3·64 ± 0·40
50 mgm. PTU/kgm. daily	160	210	16·0 ± 0·73	0·68 ± 0·18
120γ L-thyroxine/kgm. daily	160	200	6·06 ± 0·88	1·62 ± 0·48
400 mgm. AET + 120γ L-thyroxine/kgm. daily	135	190	7·14 ± 0·68	0·19 ± 0·04
50 mgm. PTU + 120γ L-thyroxine/kgm. daily	140	180	8·12 ± 0·74	0·25 ± 0·10
Control (10 per cent gum acacia)	140	190	7·62 ± 0·33	16·0 ± 1·0

Effect of Salicylate on Blood and Liver Xanthine Dehydrogenase of Rats

MILK and liver xanthine oxidase are inhibited by sodium salicylate *in vitro*[1]. Bergel *et al.*[2] were able to utilize this property for the stabilization of xanthine oxidase by adding salicylate to the process of purification of the enzyme.

Adult white rats of the Wistar strain were used for the determination of the *in vivo* effect of salicylate on blood and liver xanthine dehydrogenase. Rats were injected intraperitoneally by a single dose of 0·5 mgm. of sodium salicylate per gm. body-weight, and xanthine dehydrogenase activity on liver and blood serum determined 4 hr. after the injection by methods previously described[3].

Blood serum of normal rats showed values of 29·0 ± 6·9 µgm. formazan/ml. serum/30 min. at 37° C. In the injected rats the average value was 40·4 ± 5·4 µgm. formazan/ml. serum/30 min. These results show an increase of xanthine dehydrogenase activity which is statistically significant (normal, $t = 4{\cdot}2$, $P < 1$ per cent; injected, $t = 7{\cdot}4$, $P < 1$ per cent). 24 hr. after the injection, this value decreased to 25·2 ± 7·0 ($t = 3{\cdot}6$, $P < 2$ per cent). On the other hand, liver from injected rats presented a loss (82·67 per cent inhibition) in xanthine dehydrogenase activity (Table 1).

Table 1. EFFECT OF SALICYLATE IN RAT LIVER XANTHINE DEHYDROGENASE*

	Without dialysis		With dialysis	
	Mean	Range	Mean	Range
Normal	675	217–1,865	891	257–1,814
Salicylate	117	0– 366	254	128– 308
Inhibition (per cent)	82·67		71·50	

* µgm. formazan/gm. dry liver/60 min. at 37° C.

Since salicylate could be removed from the enzyme by dialysis, with full restoration of the enzyme activity[1] even after prolonged association[2], we were interested to know if this *in vivo* inhibition of rat liver xanthine dehydrogenase by salicylate was also restored by dialysis. Dialysis of liver homogenate against distilled water in the cold gave the results summarized in Table 1.

In vitro experiments with a final concentration of $M/10$ sodium salicylate showed an inhibition of rat-liver xanthine dehydrogenase activity (60–70 per cent inhibition) and also of the blood-serum enzyme (50–100 per cent inhibition).

The low restoration of xanthine dehydrogenase activity obtained by dialysis of liver homogenate (Table 1) from injected rats shows that the *in vivo* inhibition of the xanthine dehydrogenase activity is possibly not only due to a loose bond (split by dialysis) between the salicylate and the enzyme. Definitive liver damage occurs in rats given 400 mgm. of sodium salicylate/kgm./day[4]. Since the loss of enzyme protein from liver tissue seems to be a general phenomenon which accompanies cell destruction in certain conditions[5], it seems probable that with the dose used by us (500 mgm./kgm.) the flow of the liver xanthine dehydrogenase, which is a soluble protein[6], to the blood serum results in a decrease of the enzyme activity in liver and consequently an increase of the blood serum xanthine dehydrogenase activity.

We are indebted to Dr. G. G. Villela for his help and advice. This investigation was supported by grants from Conselho Nacional de Pesquisas.

Re-ingestion in *Lepus capensis* L. and *Ochotona roylei* Ogilby

THE domestic rabbit produces special soft fæcal pellets which are normally taken back into the stomach direct from the anus[1,2]. This behaviour, which has been termed coprophagy, refection[2] or more appropriately re-ingestion[3], has been observed in wild rabbits[4] where it has been shown to follow a regular daily rhythm, beginning about sunrise and ending in the early afternoon[3,5].

Re-ingestion, following a similar rhythm, has since been observed in *Lepus europaeus*[6], *L. californicus*[7], *L. townsendii*, *L. americanus* and *Sylvilagus transitionalis*[8], and evidence has been reported of re-ingestion in *S. palustris*[9] and *S. floridanus*[10].

The present communication reports the occurrence of re-ingestion in another leporid and the first report from the Ochotonidae, thus supporting Watson and Taylor's[6] suggestion that re-ingestion is a normal feature of lagomorph biology.

The material was collected from an ablation valley on the northern side of the Barpu Glacier, in the Gilgit Agency of Pakistan, at an altitude of 11,000–13,000 ft. The lower part of the valley was rough grassland where hares (*Lepus capensis*) were abundant, and higher up this was replaced by a juniper association (*Juniperus turkestanica* Korn) growing on boulder banks, where the pikas (*Ochotona roylei*) lived. Three pikas and 19 hares were shot at different times of the day and nine pikas were trapped at night.

Table 1 groups the 19 hares examined into 2-hr. periods from 0600 hr. to 2000 hr. Between 0800 hr. and 1400 hr. soft fæces were found in the recta, the criterion of active re-ingestion[3], and in some of these hares amorphous fæcal material was also found in the cardiac end of the stomach. In one hare, which had a tapeworm in the duodenum, a gravid proglottis was found with the fæcal material in the stomach. Since no hares were shot at night, these observations

Table 1. INCIDENCE OF RE-INGESTION IN *L. capensis*

Time	No. examined	No. with soft fæces in rectum
0600 hr.	1	0
0800	5	0
1000	3	1
1200	2	2
1400	5	5
1600	—	—
1800	—	—
2000	3	0
Total	19	8

are not sufficient to show the full rhythm; but the incidence of re-ingestion conforms closely to that reported for other species of *Lepus*.

Among the 12 pikas examined four had soft pellets in the rectum and six had soft pellets or amorphous material in the cardiac end of the stomach. In one animal hard pellets were seen in the rectum posteriorly and soft pellets near the colon, and in another soft pellets were seen near the anus and hard pellets near the colon, indicating that these two animals were respectively beginning and ending re-ingestion. The daily rhythm in *Ochotona* does not emerge from this material; but, since the three animals shot in the daytime did not have soft fæces in the rectum and four of the animals trapped at night did, re-ingestion in *Ochotona* may occur at night in contrast to the Leporidae so far examined.

Ineffectiveness of Molybdenum, Osmium and Cobalt in Dietary Necrotic Liver Degeneration

In our past, comprehensive experience in the fractionation and purification of Factor 3 from various source materials, using the prophylactic rat test against dietary liver necrosis as an assay, it has been obvious that the Factor 3 effect was caused by a highly specific, potent, protective ingredient. The latter was recognized to be an organic selenium compound[1]; this, in turn, led to the realization that selenium is an essential micronutrient. Selenite-selenium was found to prevent necrotic liver degeneration, with a 50 per cent effective dose-level of 2·2 μgm. per cent and full protection at levels of approximately 5 μgm. per cent selenium in the diet. Factor 3-selenium is 3–5 times as potent[2].

Bunyan, Edwin and Green, on the other hand, have recently published preliminary results suggestive of protective effects of molybdenum, osmium and cobalt[3]. Their results stand in distinct contrast to earlier, unpublished results of our own. In 1953, for example, when it was discovered that molybdenum is essential for normal xanthine oxidase-levels in tissues[4,5], we had observed that 1 mgm. per cent of molybdic anhydride in the diet did not materially influence the development of dietary liver necrosis.

We have attempted to verify under our experimental conditions the findings of Bunyan and collaborators, with negative results (Table 1). Experimental details are described elsewhere[6,7]. The 30 per cent *Torula* yeast diet and weanling, inbred Fischer 344 strain of rats were employed, and the pre-depletion method was used, that is, the animals were kept for 13 days on the basal diet before start of the supplementation of test-substances. Molybdenum, osmium and cobalt, either alone or in combination, were tested at various dose-levels. They were without effect against liver necrosis even at 200, 200 and 400 μgm. per 100 gm. of diet, respectively.

Table 1. INEFFECTIVENESS OF MOLYBDENUM, OSMIUM AND COBALT IN DIETARY NECROTIC LIVER DEGENERATION

* Group average of reciprocals of individual survival-times (× 100). All experiments were terminated on the thirtieth day, and velocity of 0 was assigned to survivors.

† Published previously (ref. 2).

The question arises as to what possible cause there may be for the discrepancy between the results of Bunyan *et al.* and ours. It is our experience that differences such as those reported by Bunyan *et al.* are not significant if they are not consolidated by repetition of the experiment. However, the authors observed at least the delaying effect of the *combination* of the three trace elements twice. The statistical validity of such results can be assessed if the velocity of the development of the disease (V_{st}) is calculated for each group by computation from the individual reciprocals of the survival times[6]. For animals surviving indefinitely, $V_{st} \rightarrow 0$. Among various alternative explanations, the three trace elements may act through influencing appetite. Results available on the toxicity of molybdenum, osmium and cobalt salts are sporadic, but it appears that the doses used by Bunyan *et al.* are below those reported by others to be toxic. However, it must be kept in mind that the minimum chronic toxic dose-levels vary considerably with the general composition of diets. A restriction of dietary intake, or its reduction by other means such as chronic poisoning, delays or completely prevents the development of liver necrosis[8]. A chronic, toxic influence could make itself felt more effectively in their studies than in ours, since they require on the average 55–60 days for the production of liver necrosis, with a wide range of survival-times, and survivors in the control groups even at the hundredth day. This compares with an average survival-time of 21 days under our conditions, with much less statistical variation but small numbers of survivors after 30 days. Our animals died approximately 8 days after the start of the supplementation of the trace element. Food consumption was measured in 10 of the groups listed in Table 1. There were no significant differences. Interaction between the trace elements and some essential ingredient in the diet may also play a part. The explanation that molybdenum, osmium and cobalt act through participation in oxidation-reduction mechanisms within the organism, thus alleviating the defect existing in intermediary metabolism under pre-necrotic conditions[9], also may pertain, as mentioned by Bunyan *et al.*

It is obvious from our findings, however, that molybdenum, osmium and cobalt are not of primary importance in the prevention of dietary necrotic liver degeneration. If they have a moderating influence at all, it would be of a secondary nature.

Fractionation of Brain Extracts for Acid Phosphatase-elevating Activity

IN a previous communication[1] it was demonstrated that *in vitro* incubation of rat pituitary with whole aqueous hypothalamic extract increased acid phosphatase activity in the pituitary gland. Temporal lobe extract had no such effect. The results of a study of the effect of individual fractions of the extracts are given below.

Ten excised portions of the base of rabbit brains (median eminence, base of the third ventricle and the adjacent parts; below, hypothalamus), with a total weight of 3·33 gm., were homogenized in 50 ml. 0·45 per cent sodium chloride solution and frozen at − 20° C. The following day the insoluble material was separated by centrifugation at *p*H 6·8 and the extract was divided into the following three fractions, which were lyophilized: (I) *p*H 6·8–7·0, 25 per cent ethyl alcohol; (II) *p*H 4·8 ± 0·1, 40 per cent ethyl alcohol; (III) lyophilizate of the residue (low molecular substances). Aliquots of the individual fractions, corresponding to 1/10 of a rabbit hypothalamus, were mixed with 0·5 ml. distilled water containing homogenate of 1/3 rat pituitary gland, and acid phosphatase activity was determined in the mixture by the King–Armstrong method, at *p*H 5·3. Activity was expressed as King–Armstrong units/gm. pituitary (Table 1). Acid phosphatase activity of the homogenate was elevated only by the third (non-protein) fraction of hypothalamic extract. Fraction III did not itself contain acid phosphatase.

Although in the preceding experiments[1] crude temporal lobe extract had no effect on acid phosphatase activity in the pituitary gland, a further series of experiments was carried out, in which fraction III was prepared in the same way from hypothalamus and from temporal lobe. Ten rabbit hypothalami weighing 3·54 gm. yielded 200 mgm. of fraction III, and ten portions of temporal lobe weighing 3·73 gm. yielded 205 mgm. In both cases the brains were homogenized in 0·225 per cent sodium chloride solution. Equivalents of 1/10 or 1/20 of one excised brain portion were again mixed with 0·5 ml. pituitary homogenate and acid phosphatase activity expressed in King–Armstrong units/gm. (Table 2). The factor elevating acid phosphatase activity in pituitary homogenate is present in fraction III of both the hypothalamus and temporal lobe extract. In the latter it is discernibly lower.

In the final experiment in this series the influence of fraction III of both brain extracts on the acid phosphatase activity of other tissues was determined. 50 mgm. rat liver or kidney was homogenized in 10 ml. water; 0·5 ml. of this homogenate was then mixed with amounts of fraction III corresponding

Table 1

Fraction	0	I	II	III	III (without homogenate)
No. of experiments	18	14	10	10	6
Mean acid phosphatase activity (King–Armstrong units/gm. ± σ_m)	1·88 ± 0·108	1·23 ± 0·082	1·11 ± 0·296	2·86 ± 0·114	0·0 ± 0·0

Table 2

Origin of the low-molecular fraction and concentration (equivalents of one part of brain)	0	Hypoth. 1/10	L. temp. 1/10	Hypoth. 1/20	L. temp. 1/20
No. of experiments	30	12	12	18	17
Mean acid phosphatase activity (King–Armstrong units/gm. ± σ_m)	1·76 ± 0·12	4·32 ± 0·114	3·66 ± 0·147	2·82 ± 0·162	2·08 ± 0·150

Table 3

Homogenate of	Liver			Kidney		
Origin of the low-molecular fraction	0	Hypoth.	L. temp.	0	Hypoth.	L. temp.
No. of experiments	8	8	7	8	8	4
Mean acid phosphatase activity (King–Armstrong units/gm. ± σ_m)	3·52 ± 0·133	6·37 ± 0·252	5·20 ± 0·151	2·81 ± 0·420	4·64 ± 0·420	6·40 ± 0·0

to 1/10 hypothalamus or temporal lobe. Acid phosphatase activity was again expressed in King–Armstrong units/gm. fresh tissue in the homogenate (Table 3). Fraction III of the brain extracts also raised acid phosphatase activity in liver and kidney homogenate.

No explanation has yet been found for the discrepancy between the effect of fraction III of the temporal lobe extract and the ineffectiveness of crude aqueous extract of this lobe. In spite of the obvious non-specificity of the acid phosphatase-elevating activity of the fraction III of hypothalamic extract, we cannot exclude the possibility that the active factor is a hypophysiotrophic hypothalamic hormone. It is probable[2] that it is linked with the production of the thyrotrophic hormone of the pituitary gland.

Failure of Acetylcholine Release in Tick Paralysis

A MOTOR paralysis can be caused in a number of mammalian species, including man, by the continued attachment of the Rocky Mountain wood tick, *Dermacentor andersoni* Stiles[1]. The symptoms are manifested as a flaccid paralysis which begins in the hind limbs and ascends until ultimately the bulbar respiratory centres are involved.

Of the common laboratory animals, only dogs, guinea pigs and hamsters are subject to paralysis following the bite of this tick, and they are not invariably affected. We, and Gregson[2], have found that the only animal which has always been affected is the ground hog *Marmota flaviventris avara* (Bangs), the only variable being the time taken for the symptoms to appear. This latter is apparently dependent upon the number of attached ticks and their rate of feeding. The experiments to be described here have all been performed on ground hogs, using ticks that were collected from their natural environment in the vicinity of Kamloops, British Columbia. The animals show the typical picture of an ascending flaccid paralysis which ultimately involves the muscles of respiration. The only inconsistency in this progression of the condition is that very early the normal piercing cry of the animal is lost and is replaced by a hoarse grunt, seemingly due to involvement of the vocal cords. Another characteristic feature of tick paralysis as evidenced in most animals is the rapid disappearance of the symptoms following removal of the tick. This is not true of the condition in ground hogs in which death frequently ensues once the paralysis has become evident, even though the tick is removed. There is good evidence that the paralysis is not caused by the transmission to the host of a virus or of a micro-organism, but that it is due to a toxin secreted by the tick[1].

There can be little doubt that there exists in this condition a peripheral neuromuscular block. This has been shown by Rose and Gregson[3] and by Murnaghan[4] to be true in other animals; and we, as well as Gregson[2], have confirmed it in ground hogs. Adult ground hogs were paralysed 18–36 hr. after 4–7 partially engorged female ticks were allowed to attach themselves, and experiments were conducted at a time when respiratory difficulty first became noticeable. Records of the twitches of the gastrocnemius, tibialis anterior and brachialis muscles have been made following maximal electrical stimulation of the appropriate motor nerves, and the tensions developed in the muscles of fully paralysed animals are never more than 5 per cent of those found in controls. The response to repetitive stimulation (twenty impulses per sec.) is poorly maintained, and there is no evidence of a post-tetanic potentiation of the response to a single shock such as may be attained in a partially curarized preparation. The muscles remain directly excitable throughout.

Murnaghan[4] has reported that in one fully paralysed dog the threshold dose of acetylcholine required to produce a muscle twitch following intra-arterial injection was much reduced, resembling the enhanced sensitivity found after denervation. We have failed to confirm this in four fully paralysed ground hogs. The concentrations of acetylcholine required to elicit a detectable electromyographic response (recorded with a concentric needle electrode) was the same for both control and paralysed animals.

Perfusion of the hind limb of ground hogs was achieved following cannulation of the common iliac artery and vein. A 'finger' pump was used to give a pulsatile flow of the perfusion medium, which consisted either of reconstituted human serum or Tyrode's solution, both equilibrated with 95 per cent oxygen–5 per cent carbon dioxide and containing 10 mgm./l. of eserine sulphate. The main trunk of the sciatic nerve was maximally stimulated at a frequency of 10/sec. Acetylcholine was assayed by observing the ability of the effluent perfusion fluid to depress the blood pressure of the eviscerated cat.

The results, which are shown in Table 1, indicate clearly that in the paralysed animals there is a lack of release of acetylcholine into the perfusion fluid as a response to stimulation of the sciatic nerve. Whether this failure is due to a deficient synthesis of acetylcholine or to an impaired release of the substance from the endings of the motor nerves must await further investigation. In either event, however, it is difficult to allow that this peripheral action brought about by

Table 1. RELEASE OF ACETYLCHOLINE IN PERFUSED GROUND HOG LIMBS.
Acetylcholine gm./min. × 10^{-9}

	Unstimulated			Stimulated		
	First 5-min. period	Second 5-min. period	Third 5-min. period after stimulation	First 5-min. period	Second 5-min. period	Third 5-min. period
Normal	6·8	2·1	0	46	28	11
	0	0	1·4	12	13	8·2
	8·9	10	—	25	—	—
Paralysed	4·0	4·1	0	4·6	4·6	3·3
	0	0	0	3·4	0	0
	1·9	3·1	5·3	5·6	7·1	8·0
	0	7·0	0	0	0	0

the tick toxin can be the only one. *A priori* there seems no reason why any given muscle should be preferentially affected, and one would expect to see a gradual generalized weakening of the skeletal musculature rather than the orderly ascending progression of paralysis which is the observed fact. We conclude that in addition to the peripheral, there is likely to be some central nervous system component to the syndrome which is as yet undefined.

Colloid Osmotic Pressure of Rheumatoid Synovial Fluid

THE colloid osmotic pressure of rheumatoid synovial fluid samples was measured before and after intra-articular hydrocortisone treatment using collodium membranes and a hydrostatic compensation system[1]. Previously, it had been found that contents of vacuum-dried synovial fluid adsorbed decreased volumes of water after cortisone treatment[2]. The results are presented in Tables 1 and 2, but a detailed account on the material is given elsewhere[3].

Table 1. CHANGES OF COLLOID OSMOTIC PRESSURE (IN CM. WATER) OF RHEUMATOID SYNOVIAL FLUID IN CONNEXION WITH HYDROCORTISONE TREATMENT

Clinical effect	No. of cases	Treatment Before	Treatment After	Difference	P
Poor	6	42·3	38·2	−4·1	0·05
Moderate	7	42·3	38·0	−4·3	0·05
Excellent	11	42·4	33·0	−9·4	0·001
All cases	24	42·4	35·7	−6·7	0·001

Table 2. COLLOID OSMOTIC PRESSURE (IN CM. WATER) OF SYNOVIAL FLUID AND SIZE OF THE EFFUSION (CASES OF STAGES I–II ONLY; $P < 0\cdot05$ WITH ANALYSIS OF VARIANCE)

Size	No. of cases	Mean and range	
Moderate	7	41·8	(38–46)
Large	8	44·3	(40–58)
Very large	6	46·3	(42–51)

The colloid osmotic pressure could be correlated with the total protein ($r = 0\cdot66$; $P < 0\cdot001$) and with the blood erythrocyte sedimentation rate ($r = 0\cdot70$, $P < 0\cdot001$) but not with the concentration of synovial fluid sodium, potassium, chloride or hyaluronate or with the intrinsic viscosity. With the size of effusion a relation could be established only in the cases of Stages I–II (roentgenologically non-advanced).

It is concluded that the changes in the protein concentration and consequently in the colloid osmotic pressure of the synovial fluid are of importance in the formation and disappearance of the effusion. It may be argued that if the protein actually passes into the synovial cavity, its colloid osmotic pressure cannot have any significance. Admittedly, in the genesis of traumatic effusions a permeability damage is more important, and in the anatomically more advanced cases with stiff joints the colloid osmotic pressure is generally lower ($P < 0\cdot001$) and seems immaterial. However, submitting the observed clinical and chemical correlations as circumstantial evidence, we suggest that the increased colloid osmotic pressure may prevent the normal resorption of fluid from the synovial cavity in rheumatoid arthritis.

The polysaccharide does not seem important in the maintenance of the colloid osmotic pressure. The significance of the qualitative and quantitative changes in the hyaluronate should be sought from the analogies with the connective tissue response to inflammation.

Inactivation of Spores of *Bacillus anthracis* by γ-Radiation

THE bactericidal effect of ionizing radiation has been recognized for many years; but it is only recently that serious attention has been given to this method of sterilization for foodstuffs[1] and for pharmaceutical and other products[2,3]. This is due mainly to the increased availability of radioactive isotopes. In this respect γ-radiation seems to be the most useful due to its effective depth of penetration, and the most convenient sources of γ-radiation are cobalt-60 and cæsium-137.

The present communication records the results obtained from a preliminary investigation into the sterilizing efficiency of γ-radiation against spores of *Bacillus anthracis*. Eight strains of *B. anthracis* were used.

Spore suspensions were prepared by inoculating 5 ml. of 'Yeastrel' broth with the test organism; after incubation for 72 hr. the culture was heated at 60° C. for 30 min. The approximate number of viable spores remaining was determined by adding 0·1 ml. of the heated suspension to 100 ml. of broth and then spreading 0·1 ml. of the diluted material over the surface of a dish of 'Yeastrel' agar. If at least 100 colonies grew, this indicated a viable count of at least 10^6 spores/ml. and the suspension was used in the experiment. If less than 100 colonies grew, the suspension was rejected and another culture prepared.

Approximately 0·5 gm. samples of washed goat hair were compressed in test-tubes 15 cm. × 1·5 cm., stoppered with cotton-wool plugs and sterilized by autoclaving at 15 lb./sq. in. for 15 min. Each sample of hair was contaminated by adding to the tube 1 ml. of a spore suspension in broth of the test organism. The samples were then dried at 56° C. for 48 hr. and allowed to stand in the incubator at 22° C. for 4 weeks.

Samples of contaminated hair were treated with increasing doses of γ-rays from a cobalt-60 source. The dose-rate was varied (from 10^4 rad/hr. to

2×10^5 rad/hr.) by altering the distance of the samples from the source. All irradiations were carried out at room temperature, and doses are given with a maximum error of ± 5 per cent.

In a pilot experiment six of the eight strains of *B. anthracis* were used. Each organism was exposed to radiation from a cobalt source at 200,000 rad/hr. for periods of 3, 7, 9 and 15 hr. (actual doses: 0·58, 1·42, 1·80 and $3{\cdot}0 \times 10^6$ rad).

After irradiation, each tube was tested for sterility by adding 10 ml. of 'Yeastrel' broth and incubating at 37° C. for 2 and 28 days.

Tubes which had not been irradiated were included as controls and all these showed growth in 48 hr. Similarly, growth was obtained in 48 hr. in all tubes exposed to a radiation dose of $0{\cdot}58 \times 10^6$ rad, but all other tubes were sterile even after 28 days incubation (Table 1).

Table 1. VIABILITY OF SPORES AFTER γ-RADIATION

B. anthracis strain	Radiation dose ($\times 10^6$ rad)				
	0·0*	0·58	1·42	1·80	3·0
1	+	+	–	–	–
2	+	+	–	–	–
3	+	+	–	–	–
4	+	+	–	–	–
5	+	+	–	–	–
6	+	+	–	–	–

* Control; +, growth after 48 hr.; –, no growth after 28 days.

A second experiment was carried out using these six strains of *B. anthracis*, together with two others, more recently isolated (kindly supplied by Prof. D. T. Robinson, Liverpool Public Health Laboratory). The organisms were exposed to a graded series of radiation doses varying from $0{\cdot}8 \times 10^6$ rad to $2{\cdot}1 \times 10^6$ rad. The accuracy of the radiation dose was again ± 5 per cent.

In a third series, the two recently isolated strains were irradiated in the range $1{\cdot}0\text{–}1{\cdot}4 \times 10^6$ rad.

The results of all three series are combined in Table 2.

Table 2

B. anthracis strain	Radiation dose ($\times 10^6$ rad)											
	0*	0·8	0·9	1·0	1·1	1·2	1·35	1·4	1·5	1·7	1·9	2·1
1	+	+	+	+	+	+	+	+	–	–	–	–
2	+	+	+	+	–	–	–	–	–	–	–	–
3	+	+	+	–	–	–	–	*NT*	–	–	–	–
4	+	+	*NT*	*NT*	*NT*	*NT*	*NT*	–	*NT*	*NT*	*NT*	*NT*
5	+	+	+	+	+	–	–	–	–	–	–	–
6	+	+	+	+	–	–	–	*NT*	–	–	–	–
7	+	*NT*	*NT*	+	+	+	*NT*	–	*NT*	*NT*	*NT*	*NT*
8	+	*NT*	*NT*	+	+	–	*NT*	–	*NT*	*NT*	*NT*	*NT*

* Control; +, growth after 48 hr.; –, no growth after 28 days; *NT*, not tested at this level.

From this it will be seen that the most sensitive strain of *B. anthracis* failed to grow after $1{\cdot}0 \times 10^6$ rad while the most resistant needed $1{\cdot}5 \times 10^6$ rad for inactivation.

These experiments were carried out with the view of determining the applicability of γ-radiation to the sterilization of imported goat hair. In the United Kingdom this substance is at present subjected to a formaldehyde treatment as laid down in the Anthrax Act of 1919.

On the basis of our results a dose of $1{\cdot}5 \times 10^6$ rad is sufficient to ensure the inactivation of a high concentration of spores of all the strains of anthrax used. Further experiments are in hand using a larger number of strains to find more certainly the natural variation in radiation resistance. Pending the completion of the experiment we suggest that a minimum dose of $2{\cdot}0 \times 10^6$ rad would provide a sufficient margin of safety in an industrial process for the inactivation of *B. anthracis* in baled goat hair.

Phagocytosis and Cell Division

MOST investigators believe that reticulo-endothelial cells, through ingestion of the antigen, play an initial part in the synthesis of antibody[1,2]. Study of phagocytosis of particulate antigens lends support to this concept[3]. Since antibody is merely one form of protein, its formation could theoretically occur immediately; however, it appears to be delayed several hours or days[4].

It has recently been thought that when antibody does appear it is most closely associated not with the reticulo-endothelial cell but with the plasma cell[5], although lymphocytes[6] and eosinophils have also been implicated[7].

Some investigators believe that plasma cells and lymphocytes are derived from reticulo-endothelial cells and that during the process of division and differentiation the antibody-producing mechanism is automatically transferred to the daughter cell[8]. However, other workers feel that some way other than division must be postulated to explain transfer of the antibody stimulus from the reticulo-endothelial cell to the plasma cell. They point out that cells which have ingested large quantities of carbon are unable to divide, and conclude that reticulo-endothelial cells after ingestion of the antibody could not divide and differentiate into plasma cells[9].

While studying the process of phagocytosis in L strain fibroblasts, we made some observations which may be applicable to this problem. These cells were grown routinely in suspension tissue culture as single cells, in Eagle's medium and 10 per cent horse serum as described previously[10]. Cultures (70 c.c. in volume) were incubated for 1 hr. at 37·5° with 1 mgm. carmine particles. Following incubation, the cells were washed free of carmine and resuspended in fresh medium. If the incubation was continued for 3 hr., the cells ingested a great many carmine particles and were unable to divide, and the cells usually died over a period of 3–5 days. However, cells which had ingested only 3–6 carmine particles per cell underwent normal division with a generation-time of approximately 28 hr., similar to the control cultures. No abnormal mitotic figures were noted, and the particles distributed themselves in the cytoplasm during mitosis (Fig. 1).

Some investigators believe that fibroblasts and macrophages are derived from reticulo-endothelial cells and that they may revert to their original form[11].

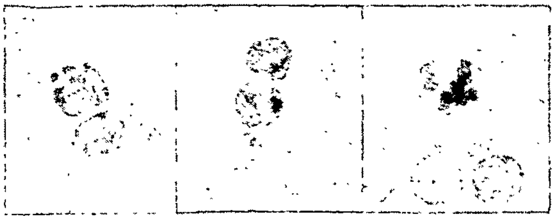

Fig. 1. Several fibroblasts have phagocytized carmine granules. Two cells are in anaphase. Aceto-carmine stain. (× 450)

Regardless of the truth of this statement, our experiments show that a phagocytic cell may ingest large amounts of foreign material and afterwards undergo division. By analogy, it lends support to those who believe that the phagocytic reticulo-endothelial cell may ingest a foreign protein antigen and retain the ability to divide. If a reticulo-endothelial cell does differentiate into a plasma cell, these observations also support the unified concept of ingestion of antigen and production of antibody within a single cell.

This investigation was supported by a grant from the U.S. Public Health Service *C*2928(*C*).

Inhibitory Action of Amino-Acid Esters on the Production of Extracellular Amylase by *Penicillium chrysogenum*

WASHED mycelium of *Penicillium chrysogenum* will not synthesize amylase except in the presence of starch. Production cannot be increased by adding amino-acids to the medium.

Amylase production by the mycelium of washed *Penicillium chrysogenum* strain Wis. 49–133 was studied. The mould was grown for 48 hr. in a medium containing soluble starch. The dry-matter content was 0·62 gm./100 ml. of incubated medium. The experimental conditions were as follows: *Penicillium chrysogenum* was grown at 24° C. in 200 ml. of medium in a 500-ml. Erlenmeyer flask on a rotary shaker (300 r.p.m., 2 cm. radius). The medium for the inoculum was composed of (per cent) glucose, 2; sodium nitrate, 3; potassium dihydrogen phosphate, 0·1; $FeSO_4.7H_2O$, 0·1; $MgSO_4.7H_2O$, 0·05; potassium chloride, 0·05; it was adjusted to *p*H 6·5 before sterilization and 0·5 per cent calcium carbonate was added before inoculation. The flasks were inoculated with a spore suspension. Mycelium was produced in the same medium. The energy source varied, but the concentration was always 2 per cent. Inoculations were carried out with 3-day-old inoculum. Mycelium production lasted for 48 or 72 hr., depending on the source of energy. Washing was done with 6 vol. of distilled water with filtering. The dry-matter content was determined by drying at 105° C. after filtering and washing with acetic acid. Enzyme production proceeded on a rotary shaker at 24° C. Mycelium suspended in 50 ml. of distilled water and 25 ml. of distilled water, or the indicated substance dissolved in distilled water, was added to 25 ml. of 0·4 per cent potassium dihydrogen phosphate and 0·4 per cent soluble starch (adjusted with potassium hydroxide to *p*H 6·5 before sterilization), in a 500-ml. Erlenmeyer flask. Amylase was determined in filtered samples of the incubated medium at 28° C. using the method of Smith and Roe[1]. Every step of the experiments was carried out under aseptic conditions and was afterwards tested for sterility.

Table 1 illustrates enzyme production as a function of time. The results are typical of induced enzyme synthesis. Identical results were obtained with mycelium grown on a wide variety of energy sources (glucose, lactose, sorbitol and glycerol), and most strikingly, even when the mould had been grown in a medium containing starch. Amino-acid esters have been found to be capable of inhibiting this enzyme production. Table 1 shows experiments carried out with glycine ethyl ester. Results similar to these were obtained with D-phenylalanine methyl ester and L-*iso*leucine methyl ester. A mixture of glycine and ethanol corresponding to a 10^{-2} *M* concentration of glycine ethyl ester, 10^{-2} *M* glycine amide and 10^{-2} *M* glycylglycine ethyl ester, were found to have no effect on enzyme production. The washed mycelia of mould, grown on various energy sources, all displayed the same behaviour in our inhibition experiments.

Table 1

Time (hr.)	Amylase (U/100 ml.)					
	Glycine ethyl ester hydrochloride (*M*)				Glycine and ethanol (see text)	
	10^{-2}	5×10^{-3}	10^{-3}	5×10^{-4}		
0	3	1	1	1	0	0
2	0	1	2	0	0	0
4	1	2	20	27	28	31
6	4	13	92	139	148	156
8	9	22	127	155	207	201
10	9	24	114	166	198	195
12	8	19	105	164	198	196
14	10	20	108	176	206	204
16	7	19	98	163	206	206

The activated carboxyl groups of the amino-acids should take part in the synthesis of peptides. These activated carboxyl groups are capable of reacting with hydroxylamine giving rise to hydroxamic acid[2,3]. Like hydroxylamine, the amino-group of the amino-acid esters possesses a marked reactive capacity.

Appearance of a Phosphorus Compound in Platelet-rich Plasma on Clotting

PREVIOUS experiments have shown that when clotting begins in human plasma containing platelets ('platelet-rich plasma'), adenosine triphosphate rapidly disappears from platelets with little or none of it appearing in the serum[1]. Other experiments suggested that in such plasma a phospholipoprotein is formed which is later broken down, and that this may be plasma thromboplastin[2].

Under the conditions used in those experiments fibrin appeared 5–10 min. after citrated plasma was recalcified. Since then a technique has been developed which leads to the formation of the clot within 2 min. With this technique the activity of thromboplastin in plasma reaches its maximum within 5 min. During that time there is not only a considerable breakdown of platelet adenosine triphosphate but also the appearance of a water-soluble phosphorus compound. This compound is the product of the breakdown of either phospholipid or phosphoprotein in the plasma.

To demonstrate this we made use of blood obtained from patients suffering from polycythæmia vera. The patients were being treated with phosphorus-32; some of this was incorporated into their plasma phospholipids and phosphoproteins which became radioactive. We observed the fate of this radioactivity during clotting. A representative experiment was as follows:

A male patient aged seventy-two was given 5 mc. of phosphorus-32 intravenously. After 48 hr., 200 ml. of blood was obtained from an arm vein and mixed with 4 ml. of 19 per cent (w/v) sodium citrate. The blood was centrifuged at 1,500*g* and 0–1° C. for 20 min. The plasma was removed and centrifuged at 22,000*g* for 15 min. to sediment the platelets. The supernatant platelet-free plasma (40 ml.) was dialysed at about 4° C., first against 3 l. Krebs–Ringer phosphate solution for 2 hr., and then for 18 hr. against 3 l. Krebs–Ringer bicarbonate solution modified so as to contain no phosphorus[2] and no glucose. The reason for dialysing against the phosphate solution was to reduce the specific activity of exchangeable phosphorus, and against the bicarbonate solution to reduce the concentrations of water-soluble phosphorus compounds in the plasma. After dialysis the concentration of inorganic phosphorus in plasma was 6·0 μgm./ml. and its specific activity was 0·6 counts/min. μgm. The specific activity of the plasma phospholipids was 14·7 and that of the plasma phosphoproteins 10·7 counts/min. μgm. phosphorus.

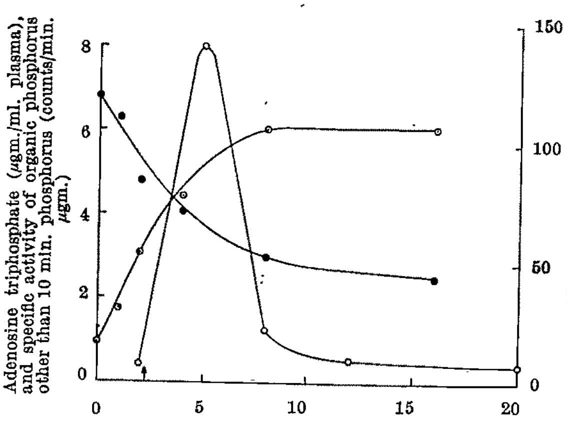

Fig. 1. Changes in the concentration of thromboplastin (○) and of adenosine triphosphate (●), and in the specific activity of organic phosphorus other than 10 min. phosphorus (⊙), in platelet-rich plasma during clotting. Calcium chloride was added at 0 min., and the clot formed after 2·3 min. as shown by the arrow

Samples (5 ml.) of dialysed plasma were incubated at 37° C. in glass tubes, the inner walls of which had been roughened by grinding. Platelets obtained from a healthy person were mixed with the plasma and 0·125 ml. *M* calcium chloride was added to each sample. The activity of thromboplastin was assayed at intervals of a few minutes. After 0, 1, 2, 4, 8 and 16 min., 1 ml. of 60 per cent (w/v) trichloracetic acid was added to a tube and thoroughly mixed with the clotting plasma. The tubes were cooled in ice and centrifuged at 0° C. for 5 min. at 22,000*g*. The clear supernatant solutions were decanted and retained. The precipitates were re-extracted with 5 ml. 10 per cent trichloracetic acid and the extracts were added to the first supernatants. The solutions were analysed for adenosine triphosphate by the firefly method[3]; and for inorganic phosphorus, organic phosphorus set free by *N* hydrochloric acid in 10 min. at 100° C. (10 min. phosphorus), and total phosphorus by the method of Berenblum and Chain[4]. The radioactivity of the phosphorus fractions was determined and expressed as counts/min. μgm. phosphorus.

The results are shown in Fig. 1. The activity of thromboplastin increased steeply after 2 min., reached a maximum after 5 min. and then decreased almost equally rapidly. Adenosine triphosphate began to disappear within the first minute after the addition of calcium, and continued to do so at a decreasing rate for 16 min. At the time when the activity of thromboplastin was maximal almost half of the adenosine triphosphate had gone.

Also within the first minute there was an increase in the radioactivity of the trichloracetic acid solutions. This radioactivity continued to increase for about 8 min. and then remained constant. It was accounted for by an increase in the specific activity of organic phosphorus other than 10 min. phosphorus, which rose from 0·95 to 6·03 c./min. μgm. phosphorus. Since only the phospholipids and phosphoproteins had specific activities higher than this, the radioactive organic phosphorus which appeared in the trichloracetic acid solution must have originated from one or the other.

Five other experiments of this kind gave similar results. It may be concluded that, as thromboplastin is formed in plasma during clotting, plasma phospholipid or plasma phosphoprotein is broken down with the liberation of an acid-soluble substance containing phosphorus.

We wish to thank Prof. L. J. Witts and Dr. Sheila Callendar for allowing us to obtain samples of blood, Dr. A. A. Sharp for collecting the samples, and Dr. W. D. McElroy for giving us fireflies.

Broadening of the X-ray Diffraction Lines in Teeth affected by Fluorine

THE diffraction of X-rays in the case of teeth can be investigated by a modification of the standard X-ray powder method, by producing biophysical specimens in the form of wires of tooth material by the careful cutting and filing of suitable pieces of tooth material. A 9 cm. camera of the Van Arkel type with filtered copper radiation has been used in comparing the diffraction lines from two specimens of teeth (one from a male and one from a female) which had been extracted following decay.

One of the teeth described had been surface-treated by a fluorine dental treatment approximately eight years previously, while the natural age of both teeth was similar. Cutting and filing was carried out so as to produce specimens of identical sizes, and such that one side in each case consisted of undamaged enamel: the resulting diffraction photographs are shown in Fig. 1 and it is seen that apart from the progressive broadening and blurring of higher-order lines in one photograph (from the specimen affected by fluorine, *a*), the patterns are identical.

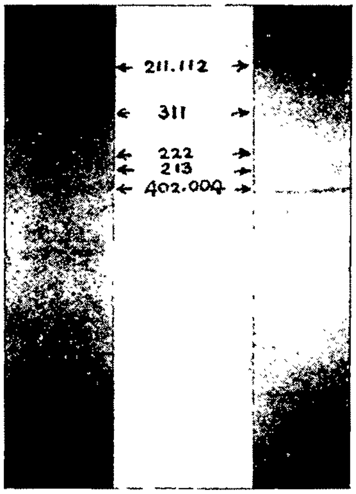

Fig. 1

The positions of the strongest lower-order diffractions were found to correspond with the hexagonal apatite form of crystal structure[1,2]. Since the teeth in their natural life must have experienced appreciable mechanical force and work of deformation, it is considered that a suggestion for the line-broadening based on normal stress/strain or grain size is less satisfactory than one arrived at by considering the variation of the surface composition within the cell-dimension limits of fluoro-apatite and chloro-apatite. This X-ray effect in hexagonal crystals has been previously described by one of us[3].

We are grateful to the Chemistry Department of the University of Sheffield for making available X-ray facilities.

BIOLOGY

Triple Coitus in the Mealy Bug, *Planococcus citri* (Risso)

MALES of the mealy bug, *Planococcus citri*, do not feed throughout their nymphal stages of development nor after they emerge as adults. They are, nevertheless, highly active in mating during the few days of their short life as mature individuals. James[1] has observed that a single male may copulate with as many as 23 females in succession, and the average number of females fertilized by 13 individual males was 9·07. During my experience with mealy bugs cultured in the laboratory on potato, the observation has been made many times that two males will copulate simultaneously with one female while yet a third male may be attempting to do the same.

The fully winged males are quite sedentary, seldom fly, but crawl about on the potato in search of mature females. During the mating process, the females usually remain in the same spot at which they had previously settled in order to feed. It has not yet been possible to tell why a certain female in a group of equally old females attracts the males nor is it known how long after one mating the female remains attractive to males.

Simultaneous unions of two males with one female can be accomplished because of their relatively long abdomina. Usually the two males align themselves on the dorsal surface of the female; the abdomina and copulatory stylets then curve ventrally around the posterior limits of the female and both copulatory stylets and phalli penetrate the single vulva to the same extent. Both insertions are maintained by the males through considerable disturbance with a camel-hair brush, as is the case in pair matings. It is very likely, on the basis of this observation, that both copulations are genuine and that both mating acts are complete.

Behaviour of Sacculinized Shore Crabs (*Carcinus maenas* Pennant)

For some years investigations on the ecology of the common shore crab, *Carcinus maenas*, have been carried out in inshore Danish waters (the Isefjord area, Zealand) and among other things the migrations of the species were studied. In contrast to the observations from British waters of Williamson[1] and others, it was observed that during the breeding season —which in the Isefjord comprises only May and June —the berried female crabs leave the littoral areas and hide in the more saline and deeper water (maximum depth 8–10 metres) until the larvæ are hatched. After this period they return to moult and copulate with the male crabs which stay all summer in shallow water (0–1·5 metres). The annual mean salinity of the Isefjord is 19·4 per mille.

It has now been found that sacculinized crabs (that is, both male and female crabs subjected to parasitic castration by *Sacculina*) carrying an externa (containing the gonads of the parasite) behave just like the normal berried females, that is, they hide in deep water. This seems to be normal for 'externa crabs' in the Isefjord, since it was found every year during the investigation from its start in 1954. It should be emphasized that the externa stage in the Isefjord normally appears in summer and is sexually ripe in the autumn. The observations are based on material comprising many hundred infested shore crabs.

As the early stage of parasitization is visible externally only in male crabs owing to the more-or-less pronounced parasitic feminization of the male phenotype, only males have been used in the following. For practical reasons the cycle of the parasite is here divided into five stages of development (Fig. 1): (*a*) crabs containing the interna stage only, noticeable by the feminization; (*b*) crabs with the externa just developed, 2–4 mm. broad; (*c*) crabs with an externa of medium size, 5–10 mm.; (*d*) crabs with sexually ripe externa, 11–20 mm.; and (*e*) crabs showing the hole after losing the externa; infection probably stopped. As seen in Fig. 1 only stages (*a*) and (*e*), namely, crabs exhibiting the beginning and the final phase of the parasite, are common in shallow water. The tendency of the 'externa crabs' to avoid the shore areas seems to be intensified with the ripening of the externa. Catches with traps in deeper water have confirmed this picture and shown the presence there of a rather high percentage of infested crabs with externa. It must be borne in mind, however, that the duration of the stay of the 'externa crabs' in deep water considerably exceeds that of the normal berried females, sometimes amounting to about a year or even more. This means that while the stages (*a*) to (*d*) of Fig. 1 represent the parasite in crabs one year old (infested in the autumn just after their metamorphosis in 1953), the final stage (*e*) of the parasite is present in crabs metamorphosed before 1953.

Broekhuysen[2] found that normal berried female crabs often show a characteristic behaviour of "egg cleaning and airing", consisting of piercing of the egg-mass by the pereiopods, followed by periodical flapping of the abdomen. A completely similar behaviour has now been observed in infested crabs of both sexes provided with an externa. In several cases studied in aquaria these characteristic movements were observed as soon as the externa appeared, and they seem to be intimately connected with the presence of an externa. In male crabs of maximal size and without any visible feminization at all the behaviour was also observable when the small externa broke through. This behaviour was shown to be highly affected by the oxygen tension of the water, low oxygen tensions accelerating the characteristic movements in a most conspicuous way.

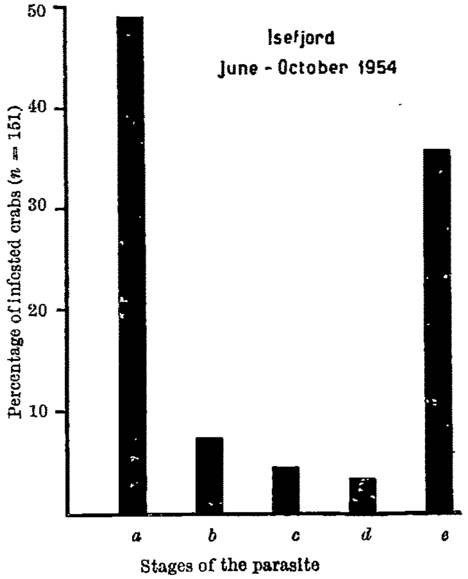

Fig. 1

The influence on behaviour caused by the disappearance of the externa shown by the field investigations was confirmed by observations in aquaria. In some cases where the externa had stopped producing its sexual products, and a slight decaying of the externa had begun, the behaviour mentioned above disappeared, and in several cases the host crab even tore the externa, and in one case was seen to be eating the remnants of the externa.

These observations suggest that only a living externa is able to promote the special behaviour seen in sacculinized crabs. It cannot, therefore, be regarded as a simple tactile response to the presence of a foreign object under the abdomen. I have made a few preliminary experiments with artificial externae fastened to the abdomen, and, though still inconclusive, they point in the same direction.

Without entering into a discussion of the various theories of the influence of the Rhizocephalous parasite on the host, I think that the behaviour of the parasitized crabs reported here may probably be interpreted as being due to a hormonal feminizing effect of the externa stage.

Histolytic Activity in Seasonal Hypertrophy of the Reproductive Organs of *Hyla aurea*

WHILE not yet reported in other frogs or in *Hyla aurea* elsewhere, hernia occurs in 0·3 per cent of this species taken in the Wellington district. The hernias seen involve various portions of the reproductive system, and are related to seasonal prebreeding organ hypertrophy. In one specimen, the uterine portion of the oviduct was ruptured through the body wall between the lateral face of the ilium and the origin of m. gluteus, to form a large mass in the dorsal lymph space. This appeared to be hernia by dissection along an anatomical pathway by pressure atrophy, as also in a second example where part of the testicular fat-body ruptured into the dorsal lymph-space between the body-wall muscles and the muscles on the lateral aspect of the ilium. A portion of the posterior lobe of the right ovary in another frog had perforated the mm. abdominis transversus and obliquus internus. This also was interpreted as based on pressure atrophy[1].

Establishment of a pathway by pressure atrophy was quite impossible in a case where an abnormally enlarged, elongated process of the right fat-body in a female had perforated the linea alba and formed a hernial mass in the ventral subcutaneous lymph-space shortly posterior to the xiphisternum. There is an absence of adhesions. It is beyond probability that a fat-body freely suspended from the dorsal aspect of the abdominal cavity could have induced atrophy by pressure in a structure such as the linea alba. Sudden mechanical pressure, such as a blow, a preformed embryonic pathway, failure of body-wall structure through postural gravity effects, interference with the vascular supply and other recognized causes of rupture likewise provided no satisfactory explanation for this case. Accordingly, it was suggested by way of hypothesis[2] that at the surface of a rapidly growing fat-body there are the mechanism of hyperplasia and hypertrophy and also a histolytic mechanism. The latter process, if induced by a substance transferable from the tip of the fat-body to the peritoneum and tissues of the linea alba, would provide a probable explanation for the establishment of the initial pathway for the hernia.

A further example in which the posterior lobe of the left ovary of a gravid adult frog extended into the left paravesical space, and, without adhesions, passed through the walls of the bladder to enter the right paravesical space and then the right femoral lymph-space where it expanded to normal size, gives further support to the above suggestion, especially since the foramen in the bladder is only 3·0 mm. in diameter, thus indicating that the bladder was perforated originally by the tip of the lobe of the ovary. The two walls of the bladder are fused around the margin of the perforation, and the lumen of the bladder closed off from the coelom. The posterior lobe of the right ovary had also ruptured into the femoral lymph-space, probably following the path established by the lobe of the left ovary.

The existence in the tadpole of histolytic processes is recognized in the tissue reductions and modifications during metamorphosis, and in the seasonal reduction of the reproductive organs following breeding. The results above indicate that a histolytic process is present during the growth and elaboration of the reproductive organs prior to breeding. It may be suggested that this process is responsible during that time for the breakdown of tissues which might otherwise cause mechanical difficulties during hyperplasia and hypertrophy of the adipose tissue in the fat-body and of the germinal tissue in the ovary. It may also assist in ovulation.

A Monogenetic Trematode New to the British Fauna

IN the course of a survey of the parasite fauna of gadoid fishes in the northern North Sea, I have examined 28 cod (*Gadus callarias* L.) from various localities along the east coast of Scotland in the second half of 1958. The fish were all less than one year old and ranged in size from 12·4 to 18·6 cm. Three of these fish were infested by a species of *Gyrodactylus* (Trematoda: Monogenea), not hitherto recorded from British waters. The parasites were attached to the gills (rakers, bars and filaments) and within the buccal cavity of their hosts. One cod was found to harbour five specimens of *Gyrodactylus* in its nostrils—a somewhat unusual habitat for this trematode genus. The numbers of parasites varied from host to host, the lowest being 6 and the highest 197 specimens. All three infested fish were caught relatively near the shore: one was taken in the Firth of Forth, 5 miles east of May Island, and two about 15 miles south-east of Stonehaven, at a depth between 55 and 68 m.

The parasites were identified by Dr. Göran Malmberg of Zootomiska Institutet, Stockholm, as *Gyrodactylus callariatis*[1]. The species was described by Dr. Malmberg from cod taken in Nämdö, near Stockholm. The dimensions of the fresh specimens are as follow:

Total length	0·42–0·70 mm.
Body width	0·09–0·18 mm.
Opisthaptor length	0·08–0·12 mm.
Opisthaptor width	0·11–0·15 mm.

The anchoring apparatus of the species is distinguished by a dorsal bar with a central process pointing posteriorly. Its ventral bar is large and provided with wide antero-lateral processes. The membrane of the ventral bar is grooved and wide at the base. The marginal hooks are long and slender.

G. callariatis differs significantly from *G. marinus*, another species of the genus found on cod in the Barents Sea and the northern Pacific[2].

The genus *Gyrodactylus* contains relatively few marine species. They infest mainly young fish in coastal areas. Like some other monogenetic trematodes, *G. callariatis* appears to be a 'childhood' parasite[3], which might be the reason why it has not so far been discovered in British waters. Young stages of fish are only infrequently used for parasitological examinations.

I have also found another species of *Gyrodactylus* on whiting, *Gadus merlangus* L., in the same area. The specimens of this parasite are at present in Dr. Malmberg's hands.

A Diagnostic Reaction of *Desulphovibrio desulphuricans*

THE sulphate-reducing bacteria at present available in pure culture are *Desulphovibrio desulphuricans*, its *aestuarii* variant[1], the thermophilic *Clostridium nigrificans* (earlier known as *D. thermodesulphuricans*[2]) and the new species *D. orientis*[3]. The species *D. rubentschickii* and its variant *anomalous*, able to utilize acetate and/or butyrate[4], have so far defied re-isolation.

Cl. nigrificans is readily distinguished from the other species by its thermophilic habit. *D. orientis* shows broad differences in appearance and motility from the *desulphuricans* pair, but is mainly distinguished by its multiple flagellation and ability occasionally to form spores, and neither of these features is technically very satisfactory for rapid diagnosis. A third distinguishing test has been devised making use of the absence of desulphoviridin[5] from *D. orientis*. The pigment desulphoviridin dissociates in alkaline solution to yield a photosensitive chromophoric group having a strong red fluorescence in ultra-violet light at 365 mμ.

The following procedure distinguishes pure cultures of *D. desulphuricans* and its *aestuarii* variant from *D. orientis*: a fully grown culture in 10 ml. of medium *C* of Butlin, Adams and Thomas[6] was centrifuged and the cells resuspended in 1 ml. water (final cell density 1·5–3 mgm. dry wt./ml.). One drop of 20 per cent sodium hydroxide was added and the suspension inspected at once in light at 365 mμ. Twenty strains of the *desulphuricans* group were tested and showed a brilliant red fluorescence; three strains of *D. orientis* did not, nor did six strains of *Cl. nigrificans*. Large amounts of ferric sulphide in the culture interfere, but may be removed by coarse filtration.

Separation of Specific and Non-Specific Effects of Chemicals on Plants

In working with the effects of chemicals on plants, it is often difficult to determine which of the effects obtained is specific to the chemical applied. For example, 2,4-dichlorophenoxyacetic acid (2,4-D) has been shown to cause numerous effects on plants. A recent review by Woodford *et al.*[1] discusses this subject in detail. It has been shown that 2,4-dichlorophenoxyacetic acid causes varied tissue changes, affects phosphorus metabolism, increases respiration, decreases photosynthesis and, in general, affects a great many functions of the plant.

Although it is true that these effects do occur on plants, it is by no means certain which, if any, of these reactions is of primary importance, and which are secondary. The living plant represents a dynamic, balanced system, and any change which affects one function of the plant will necessarily affect a great many others. Some of these changes will be associated with any type of killing mechanism; others will be specific. The data presented in many of the reports in the literature are not sufficient to establish this point. Frequently, there is no mention of whether there has been gross damage to the experimental plants, and the reader may suspect that the changes reported are simply those characteristic of damaged or dying plants.

One way of tackling the problem of which changes are of a non-specific nature is to use a control which has been allowed to die without outside chemical influence. We have attempted to do this in our experiment by digging up some of the plants, washing off the roots, and letting them lie on the greenhouse bench for the duration of the experiment. A similar technique was used by Loustalot *et al.*[2] in field experiments.

Bean plants (*Phaseolus vulgaris* L.) were grown in the greenhouse in a mixture of sand and peat soil until they were three weeks old. The beans were then selected for uniformity and treated. Foliage sprays of 1, 2, and 4 lb. per acre acid-equivalent of 2,4-dichlorophenoxyacetic acid (amine salt in water solution) were applied. There were four replicates of each treatment, and the plots were completely randomized in the greenhouse. The roots were harvested 1, 4, 11 and 18 days after treatment. Epinastic responses in the young leaves were visible on the first day after all treatments. The plants were dead in the 4 lb. treatment in 18 days. At this time, plants treated with 2 lb./acre were very stunted and malformed and those treated with 1 lb./acre apparently were recovering. Total protein content (alcohol-insoluble nitrogen) free amino-acid nitrogen, and individual amino-acids were determined as reported elsewhere[3,4]. A brief summary of the results is given in Tables 1 and 2. The trends for individual amino-acids were similar to those for total free amino-nitrogen. A fuller account of these results is in preparation.

Table 1. CHANGES OF PROTEIN IN TREATED BEAN ROOTS (MGM. ALCOHOL INSOLUBLE NITROGEN PER PLANT)

2,4-D per acre (lb.)	Days after treatment 1	4	18
0 (untreated)	2·64	2·54	2·80
1	2·90	2·58	2·51
2	2·71	—	1·60
4	2·51	2·30	1·30
0 (uprooted)	2·58	1·92	1·91

Table 2. CHANGES IN FREE AMINO NITROGEN IN TREATED BEAN ROOTS (MGM. PER PLANT)

2,4-D per acre (lb.)	Days after treatment 1	4	18
0 (untreated)	0·109	0·073	0·075
1	0·111	0·104	0·057
2	0·095	—	0·039
4	0·102	0·077	0·029
0 (uprooted)	0·114	0·090	0·006

Although pronounced changes occurred in the proteins of the plants following 2,4-dichlorophenoxyacetic acid treatment, and these changes appeared superficially to be correlated with the amount of 2,4-dichlorophenoxyacetic acid applied, it is obvious that equally drastic changes occurred in the plants that were uprooted and not treated with 2,4-dichlorophenoxyacetic acid. It appears, therefore, that these changes in the proteins and the amino-acids occurred as a result of damage or death, and not directly as a result of 2,4-dichlorophenoxyacetic acid treatment *per se*. Our results suggest, therefore, that the effect of 2,4-dichlorophenoxyacetic acid on protein metabolism is of secondary importance. They also emphasize the value of this type of control. Without this control, it would have been possible to draw exactly opposite and erroneous conclusions.

Effect of Boron Supply on the Sugars, Soluble in 80 per cent Ethanol, in Flax Seedlings

FLAX plants (*Linum usitatissimum* var. Ventnor) were grown in nutrient cultures supplied with increasing concentrations of boron. The methods were such that an addition of 0·001 p.p.m. boron to the basal medium produced a large growth response. After four weeks the plants were harvested and weighed (Fig. 1). The 0 p.p.m. boron plants grew very little throughout the four weeks; both these and the 0·001 p.p.m. boron plants showed typical deficiency symptoms in stems and roots.

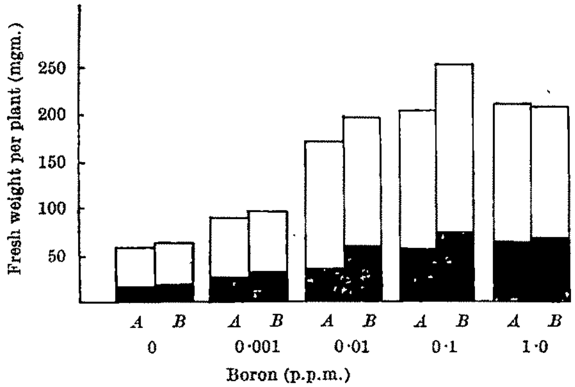

Fig. 1. Fresh weight of flax plants grown at increasing levels of boron supply. White, tops; black, roots

The plants of each treatment (which was duplicated) were divided into stem tips, the remainder of stem and leaves, and roots. These tissues were extracted with 85 per cent ethanol. Extracts, usually each equivalent to 40 mgm. fresh weight, were spotted on to No. 3 Whatman paper, and the chromatograms were eluted with a pyridine/ethyl acetate/water (80 : 20 : 10). Two chromatograms were run for each set of extracts. One was developed with silver nitrate and ethanolic sodium hydroxide; from the other the portions of paper corresponding to the sucrose, glucose and fructose spots were eluted and the sugars estimated by the method of Wager[1].

Sucrose, glucose and fructose were the principal sugars detected. Qualitative examination of the chromatogram (Fig. 2) showed no evidence that the stem tips and roots of boron-deficient plants were carbohydrate-deficient. The results of the quantitative analyses confirm this (Table 1).

Table 1. THE EFFECT OF BORON ON THE DISTRIBUTION OF SUGARS IN FLAX

P.p.m. boron in culture medium		0*	0·001*	0·01	0·1	1·0
		Sugar concentration (mgm./gm. fresh weight)				
Stem tips	Sucrose	0·90	1·85	2·18	2·00	1·57
	Glucose	3·00	2·90	1·55	1·10	1·14
	Fructose	1·98	2·48	0·67	0·32	0·39
Remainder of stem and leaves	Sucrose	0·41	0·13	0·37	0·41	0·38
	Glucose	1·75	1·40	0·73	1·40	1·00
	Fructose	1·00	0·85	0·79	0·73	0·30
Roots	Sucrose	None detected				
	Glucose	1·60	1·41	0·95	0·60	0·61
	Fructose	1·54	1·18	0·57	0·54	0·19

* Plants showing boron-deficiency symptoms.

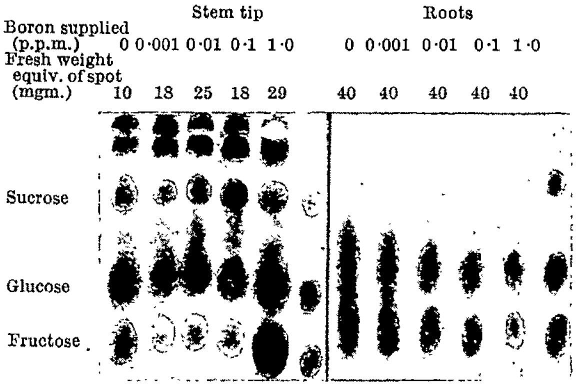

Fig. 2. The sugars in the stem tips and roots of flax plants grown at increasing levels of boron supply

Boron deficiency appears to depress the sucrose, but not the fructose or glucose content of flax stem tips. The remainder of the stems and leaves of boron-deficient plants in general contain more of the three sugars, expressed on the fresh weight basis, than normal plants, while in flax roots boron deficiency results in the accumulation of glucose and fructose.

These results do not support the hypothesis[2,3] that the cessation of growth in boron-deficient plants may be attributed to a carbohydrate deficiency in shoot tips and roots. It has further been demonstrated in this laboratory that excised flax roots grown in a specially purified sterile medium, which included 4 per cent sucrose, ceased to grow after 48 hr. in the absence of boron.

I wish to thank Dr. K. S. Rowan for advice on matters of technique.

GEOLOGY and PHYSIOGRAPHY

Trap-Shotten Rock from the Biligirirangan Hills, Mysore State, India

CHARNOCKITIC rocks have been developed over a wide area in the southern part of the State of Mysore in India. The typical charnockites are found in isolated patches of varying dimensions. The largest of these occurrences is in the Biligirirangan Hills, where a fairly continuous mass of charnockite extending more than 25 miles forms this mountainous tract which lies between 11° 40′ and 12° N. In this region peaks of more than 5,000 ft. are common on the ranges, which generally trend in a north to south direction.

For the purposes of this communication, it is not necessary to describe the petrography or the rock associations of this interesting area. Attention is directed only to the fact that this elevated region, which is composed of charnockites, rises abruptly from the Mysore plateau of Peninsular gneisses, the demarcation being an almost straight line running north–south which corresponds roughly to longitude 77° 10′ E. This junction is characterized by a zone of trap-shotten material, which when examined under the microscope is seen to contain beautiful rosettes and radiating, parallel, or matted aggregates of microlites and skeleton crystals.

The trap-shotten rock is composed of a brown matrix with abundant minute specks of iron ore, in which fragments of charnockite as well as porphyroclasts of feldspar, quartz, and hypersthene are found. The quartzes are optically strained and often granulated. In the case of the plagioclases, the twin lamellæ are generally bent and sometimes obliterated. The borders of these xenoclasts are corroded and frequently embayed.

There is no glass at present, but the brown matrix shows signs of patchy devitrification being full of microlites of some mineral (? orthorhombic pyroxene) which are arranged as in a comb with parallel bars developed on either side of the central axis.

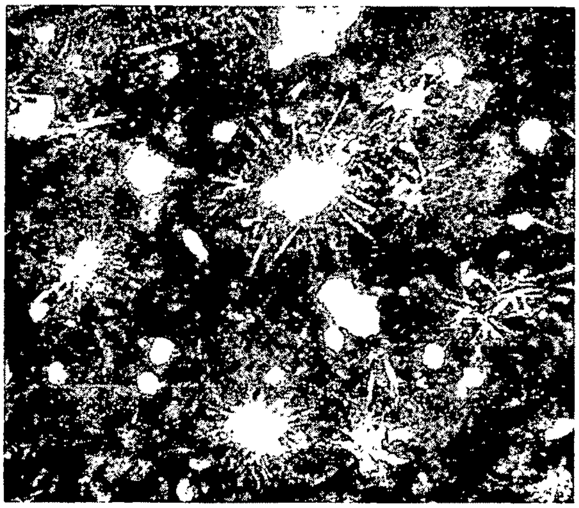

Fig. 1. Stellate aggregates of oligoclase in trap-shotten rock. The embayed quartz porphyroclasts do not serve as nuclei for the outgrowths of skeleton crystals. (× 40)

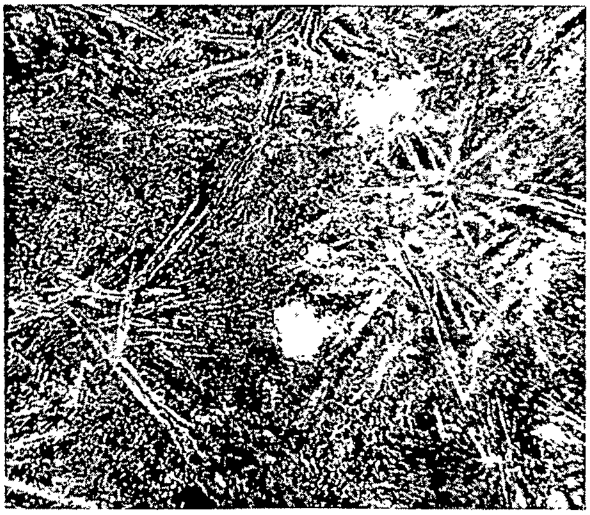

Fig. 2. Skeleton crystals of oligoclase in a devitrified irresolvable matrix. (× 160)

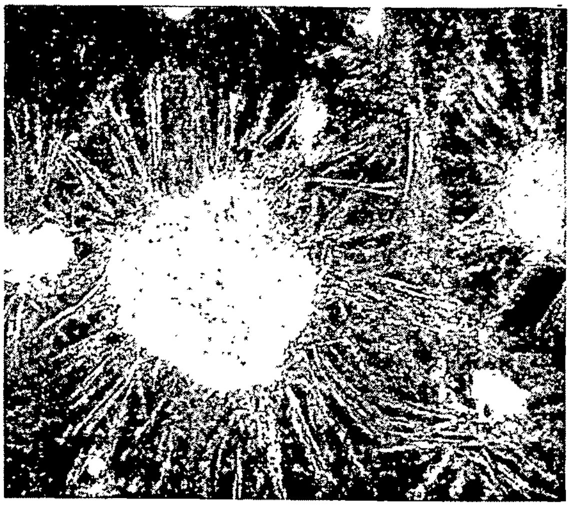

Fig. 3. Skeleton crystals of oligoclase radiating from plagioclase porphyroclasts. (× 120)

The junction between the pseudotachylyte and the country rock is quite sharp, the border being darker than the brownish interior. In some places it has penetrated into the charnockitic rock or engulfed fragments near the contact.

The most interesting feature of the pseudotachylyte is the occurrence of numerous star-shaped aggregates of skeleton crystals of feldspar (Fig. 1). The individuals are long and ladder-like, generally hollow and swallow-tailed (Fig. 2). They are also arranged in radiating patterns around porphyroclasts of plagioclase (Fig. 3). It is significant that the quartz fragments do not serve as nuclei for these outgrowths.

The extinction angle of these crystals is nearly straight, and the refractive index slightly higher than that of Canada balsam. These correspond to the characters of an oligoclase of composition about $Ab_{75}An_{25}$.

The temperature at which rocks can be fused by frictional heat has often been discussed. Shand[1], in his classification of pseudotachylytes, has listed Indian localities under "black rocks composed of crushed material without recrystallization or any evidence of elevated temperature", and doubtfully under "black rocks which bore evidence of high temperature approaching the melting points of some of the constituents, and with beginnings of crystallization". This is probably because of Holland's observation[2] that "the black material has essentially the microscopic structure of an indurated dust, never that of a rock cooled from fusion".

The example of trap-shotten rock from Mysore State described in this communication indicates that the temperature produced by friction was high enough to melt and cause the recrystallization of oligoclase in radiating aggregates.

Heavy Minerals in Certain Old Red Sandstone and Silurian Limestones of Monmouth

THE Wenlock Limestone outcrops intermittently within the inlier of Silurian rocks situated between Usk and Pontypool, and the 'Cornstones'[1] as discontinuous bands within the Old Red Sandstone of Monmouth. Samples of both limestones were crushed, dispersed, and particles with a diameter greater than 0·2 mm. removed by wet sieving, and those with a diameter less than 0·02 mm. by decantation. The residue corresponding to fine sand contains the bulk of the heavy minerals which were separated in bromoform, identified, and their relative proportions determined by microscopic counts which have been combined in Table 1.

Table 1

	Old Red Sandstone Cornstones (per cent)	Silurian Wenlock Limestone (per cent)
Zircon	56	47
Tourmaline	13	15
Rutile	11	16
Garnet	7	11
Monazite	0	6
Epidote	3	5
Enstatite	4	0
Hypersthene	2	0
Fluorite	3	0
Anatase	1	0

Prismatic zircon grains with rounded terminations constitute the bulk of the heavy mineral assemblage in both limestones, mostly of dusky hue in the Wenlock Limestone and colourless within the Cornstones. Zircons within the latter show greater variety, some showing marked red staining and containing many inclusions which, in a few grains, are sufficiently abundant to render the grain almost opaque. Pink and pleochroic brown zircons may also occur. Tourmaline prisms with rounded rhombohedral terminations, pleochroic in all shades from green to brown, are moderately abundant in both limestones. The Cornstones contain, in addition, some well-worn rounded flakes. Also moderately abundant in both limestones are rutile grains, chiefly amber, which may be prismatic with rounded or irregular terminations or of a well-rolled character. A few grains in the Wenlock Limestone are foxy-red and in the Cornstones grey. Garnets, wine-red in colour and with pitted surfaces and polygonal outline, are more numerous within the Wenlock Limestone than in the Cornstones, where most garnets are colourless, contain many inclusions, and display an intricate rectangular outline presumably due to the dodecahedral cleavage.

Some yellowish, egg-shaped grains of monazite occur only in the Wenlock Limestone. Epidote prisms with rounded or irregular terminations are mostly of the orthorhombic zoisite variety in the Wenlock Limestone and monoclinic clinozoisite variety in the Cornstones. A very few grains of yellow anatase and fluorite occur only within the Cornstones. A characteristic feature of this limestone is the presence of pyroxene, either as dusky enstatite prisms or as pleochroic green and pinkish hypersthene prisms. One grain, too altered to allow accurate identification, may possibly be augite.

Slightly pleochroic, angular, green plates of chlorite are reasonably abundant in both limestones, and may be somewhat corroded at the margins within the Cornstones. Biotite is relatively uncommon. The opaque iron oxides are very abundant in both limestones, chiefly in the form of hæmatite in the Cornstones and both hæmatite and limonite in the Wenlock Limestone, with ilmenite of lesser quantitative importance in either case. Detrital quartz showing pronounced undulose extinction and streams of inclusions is also abundant. The feldspars consist chiefly of moderately fresh oligoclase, andesine and orthoclase. Anorthite grains are also quite numerous in the Cornstones. All the minerals show at least slight evidence of abrasion and are therefore detrital in origin.

The Wenlock Limestone is inter-stratified with argillaceous rocks which are more characteristic of relatively deeper depositional waters. The Cornstones are interbedded with marls and arenaceous rocks the presence of which suggests shallower water conditions, Heard and Davies suggesting brackish water lagoons with rapidly changing conditions. The slightly greater variety of mineral species within the assemblage of the Cornstones is consistent with a shallower water depositional environment. The mineral assemblage of the latter limestone shows an expected close similarity with that of the other Old Red Sandstone strata described by Heard and Davies. There is, however, the exceptional occurrence of pyroxene in the Cornstones. This mineral, less stable than other species such as zircon, rutile and tourmaline, appears to have been preserved within the limestone. This feature of the preservation of certain less stable mineral species in limestone interbedded with sandstones and shales has been noticed by Smithson in the Jurassic rocks of Yorkshire[2].

Stability of Stone Polygons in North Wales

THIS communication describes certain preliminary observations made on stone polygons in Snowdonia during the summer of 1957, observations which appear to reveal the impermanent character of these structures. The polygon area has been briefly described by Pearsall[1]; it consists of several connected flat expanses of bare detritus, formed from the erosion of the Juncetum squarrosi occupying the broad ridge between Carnedd Llywelyn and Foel Grach summits in the Carneddau at 915–945 m. The area was casually examined several times during the summer of 1956, but no polygons were observed, the detritus being unsorted. In the course of field work during the first week of July 1957 well-defined stone polygons were noticed over the whole area (Fig. 1); each polygon was 45–60 cm. in diameter, with a centre of fine gravelly detritus and a rim, 10–15 cm. wide, of coarse stone (3–10 cm.); these coarse stones extended downwards for 10–15 cm., finally merging into a matrix continuous with the polygon centres. Ten days later, after predominantly fine weather but with a few days of rain with a blustery north-east wind, it was noticed that a large proportion of the polygons had, by apparent obliteration of the cross-connexions, been converted into stone stripes 2–4 m. long, orientated more or less at right angles to the direction of the prevailing wind (Fig. 2). For much of the remainder of July 1957 the weather was wet, with more or less permanent low cloud. On July 15 there was little change in the polygons. On July 30, however, after a fortnight of heavy rain and strong winds, a large number of the polygons and stripes had been obliterated or were in process of obliteration. On September 3 one of the areas was almost completely unsorted, and many of the stripes on the other areas were indistinct. Polygons were very rare, and the stripes had markedly elongated, extending for many metres without interruption. In July 1958, the next opportunity for a further examination, the area exhibited little change, except qualitatively in that the stone stripes appeared far less elongated.

It has been supposed that the balance between polygons and stripes is determined by slope, polygons being developed only on flat ground, elongated polygons on ground with a slope of 2–7 deg., and stripes on ground with a slope of 10 deg. or more[2]. On the area described above there is an imperceptible slope, of 1–1·5 deg. east–west, down which the stripes are orientated, but the occurrence of polygons among the stripes cannot be related to any localized flat areas. It is interesting to note that patches within the polygon area with a developing plant cover (of *Rhacomitrium lanuginosum*) have completely unsorted detritus, suggesting a recent origin for the polygons, and that areas with partly obliterated polygons are characteristically flat.

It has only recently been realized how rapid the processes of change in stone polygon and stripe areas can be. Undoubtedly many of these structures are exceedingly stable: thus photographs of polygons in the French Alps taken in 1934, 1942 and 1947 superposed exactly[2]. On the other hand, Michaud and Cailleux destroyed stone stripes in the same region in August 1947, and they had been reformed in August 1949 continuous with the undisturbed stripes[3]. The same authors marked stones in six polygons, and after two years there had been appreciable change in two of them: the stones had moved up to 10 cm. on the surface, and some of them were found buried at a depth of 13 cm. Cailleux and Taylor[2] also record polygons and stripes formed on moraines abandoned four years previously.

Thus the observations in North Wales are not unique, though the rapidity of change appears unparalleled. The winter of 1956–57 in North Wales was marked by intense cold with only minimal snow cover—ideal conditions for polygon formation (since a covering of snow reduces the depth of penetration of frost into the soil by some 2–2½ times, and delays thawing by the same factor). In normal winters the ridge between Carnedd Llywelyn and Foel Grach has a good depth of snow. The rapid changes during July 1957 appear to be related to the unusually heavy rainfall and high winds; the polygon area has a high water-table, and after heavy rain this may locally reach the surface. On July 30, 1957, the mean depth of the water-table below the polygons was 10–12 cm., but a few were still saturated throughout. It may be that during heavy rain the finer detritus becomes almost liquid and flows among the intervening larger stones, while under the influence of strong winds there may be considerable movement of these larger stones also. The observations suggest that on an area with a slope barely sufficient for 'elongated polygon' formation, cryoturbatic processes may result in the formation of more or less isodiametric polygons, but that afterwards rain and wind may accentuate the effect of the slope and result in a transformation into elongated polygons. The extremely potent erosive action of wind-driven rain at high altitudes is testified in the vegetation throughout North Wales, and the combination of relatively mild winters, high rainfall, and frequent strong winds must certainly be inimical to the continued survival of any polygon and stripe systems.

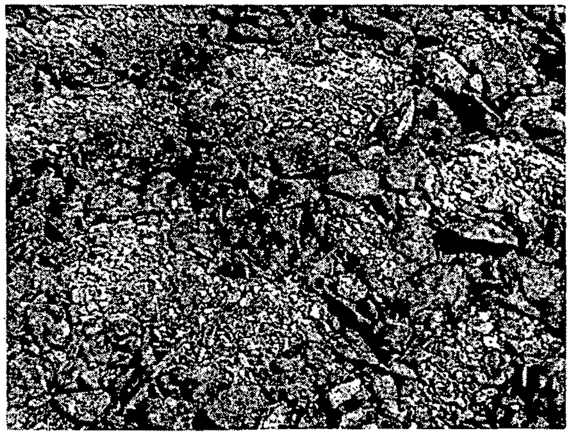

Fig. 1. Detail of stone polygons, July 2, 1957

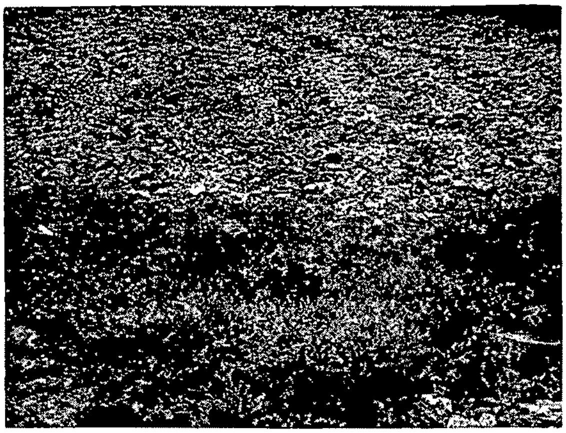

Fig. 2. General view of elongated polygons, July 15, 1957

These observations are necessarily incomplete, since the desirability of a more quantitative approach was not realized until too late, but it is believed that they are of sufficient interest to merit recording in this incomplete form.

University of London (at Senate House, London, W.C.1), at 5.30 p.m.—Prof. K. Skovgaard (Copenhagen): "The Pattern of an Unsubsidized Agriculture".*

Institution of Mechanical Engineers (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Mr. L. E. Culver and Prof. Hugh Ford: "Experimental Study of Some Variables of the Tube Expanding Process".

Society for Analytical Chemistry, Microchemistry Group (at the School of Pharmacy, 29–30 Brunswick Square, London, W.C.1), at 6.45 p.m.—Annual General Meeting. 7 p.m.—Mr. D. F. Phillips: retiring Chairman's Address.

Association of Clinical Biochemists (in the Clinical Lecture Theatre, The Middlesex Hospital, Mortimer Street, London, W.1), at 7 p.m.—Prof. C. Rimington, F.R.S.: "Porphyria".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Mr. B. C. Browne: "The Earth's Gravitational Field".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Research Manager (with an honours degree in physics or equivalent, wide research and development experience, and the ability to direct a large team of scientists) at the Research and Development Laboratories, Windscale, to direct teams engaged on research and development work for Calder Hall and for advanced designs of gas-cooled reactors—Chief Recruitment Officer, United Kingdom Atomic Energy Authority, Industrial Group Headquarters, Risley, Warrington, Lancashire, quoting Ref. 2911/J.15 (February 23).

Assistant Lecturer (with experience in experimental physics, aeronomy or astronomy) in Applied Mathematics (Geophysical)—The Secretary, The Queen's University, Belfast (February 25).

Scientific Officer (with a first- or second-class honours degree in physics, chemistry or engineering) at the Fire Research Station (D.S.I.R.), Boreham Wood, Herts, for work on the growth and spread of fire and associated combustion and fluid flow problems—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.312/8A (February 27).

Assistant Experimental Officer, for work with an electron microscope in the Plant Pathology Department—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (February 28).

Assistant Experimental Officer (male) at Dunholme Field Station, Lincoln, to work on sugar beet pests—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (February 28).

Assistant (science graduate, preferably with qualifications in physiology or biochemistry, or both) in Clinical Chemistry—The Secretary, The University, Aberdeen (February 28).

Chair of Zoology and Comparative Anatomy—The Registrar, Trinity College, Dublin (February 28).

Chemist (male, with a degree in chemistry or equivalent qualification, and preferably experience in analysis) in the Plant Protective Chemistry Section, to assist in studies of insecticides and fungicides on fruit plants—The Secretary, East Malling Research Station, near Maidstone, Kent (February 28).

Demonstrators in the Department of Physics—The Registrar, King's College (University of Durham), Newcastle-upon-Tyne (February 28).

Imperial Chemical Industries Research Fellows in Chemistry, Engineering or Physics—The Registrar, Trinity College, Dublin (February 28).

Lecturer in Applied Mathematics (Digital Computing)—The Secretary, The Queen's University, Belfast (February 28).

Lecturer in Mathematics, and a Lecturer in Physics at Kumasi College of Technology—The Council for Overseas Colleges, 12 Lincoln's Inn Fields, London, W.C.2 (February 28).

Head (with a good honours degree in chemistry or a related science, with at least a registrable qualification in pharmacy, and preferably teaching or additional practical experience in some branch of pharmacy) of the New Zealand School of Pharmacy, Central Technical College, Petone—The High Commissioner for New Zealand, 415 Strand, London, W.C.2, quoting Ref. B.11/8/5 and mentioning *Nature* (March 1).

Reader in Applied Mathematics or in Mathematical Statistics—The Clerk to the Governors, Chelsea College of Science and Technology, Manresa Road, London, S.W.3 (March 2).

Lecturer in Pure Mathematics, and a Lecturer in Applied Mathematics—The Secretary, The University, 38 North Bailey, Durham (March 4).

Lecturer (with special interests in one or more of the following: climatology, geomorphology, soil science) in Geography—The Secretary, The University, 38 North Bailey, Durham (March 4).

Imperial Chemical Industries Research Fellows in Biochemistry, Chemistry, Engineering and Physics—The Secretary and Registrar, The University, Southampton (March 7).

Lecturer or Assistant Lecturer in Applied Mathematics—The Registrar, The University, Hull (March 7).

Lecturers or Assistant Lecturers in Geography at the University of Malaya—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (March 15).

Research Fellow in Organic Chemistry, for work on natural products under the direction of Prof. R. A. Raphael—The Secretary of University Court, The University, Glasgow, W.2 (March 16).

Research Fellows (2) in the Department of Nuclear Physics, Research School of Physical Sciences, Australian National University, to work either in the field of nuclear spectroscopy or on photonuclear problems—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, March 16).

Assistant Lecturer in Mathematics—The Registrar, University College of Wales, Aberystwyth (March 19).

Veterinary Research Officer or Scientific Officer (with a degree in science, agricultural science or veterinary science, with postgraduate experience in entomology, preferably with reference to ecto-parasitology) at Wallaceville Animal Research Station, New Zealand, to specialize in ecto-parasitology research work of farm animals—The High Commissioner for New Zealand, 415 Strand, London, W.C.2, quoting Ref. No. B.11/2/14 and mentioning *Nature* (March 20).

Lecturers (2) (with interests in inorganic or physical chemistry) in Chemistry at the University College of the West Indies—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (March 21).

Assistant Lecturer (with special qualifications in petrology) in Geology—The Secretary, The Queen's University, Belfast (March 31).

Imperial Chemical Industries Research Fellows in Chemistry or Physics—The Registrar, The University, Hull (March 31).

Professor of Geology and Mineralogy at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1, or The Registrar, University of Queensland, Brisbane, Queensland, Australia (March 31).

Research Student (with a good honours degree in zoology, or good prospects of obtaining such) in the Department of Zoology, for work in river ecology—The Secretary, The University, Exeter (April 4).

Lecturers (2) in Botany—The Secretary, The Queen's University, Belfast (April 10).

Forest Utilization Officer (with an honours degree in forestry, physics or biology, able to initiate forest products research work, and preferably postgraduate experience in research and timber utilization) in Northern Rhodesia, for research work covering a wide range of forest products but primarily to improve utilization of *Brachystegia* timbers in underground conditions in the copper mines—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.61/3/02.

Junior and Senior Fellows (with at least 2 or 3 years postgraduate experience), for research in Chemistry, Physics, Mathematical Physics, Metallurgy, Chemical Engineering, Biochemistry and Food Technology—The Graduate Recruitment Officer (1344/34), U.K.A.E.A., Atomic Energy Research Establishment, Harwell, Didcot, Berks.

Laboratory Technician (male, with experience in rock sectioning, etc., photography and general laboratory maintenance)—The Secretary, The University, Exeter.

Librarian (woman, preferably with a medical or scientific background), for small medical and scientific library—Ciba Foundation, 41 Portland Place, London, W.1.

Physicist (with a good honours degree) in the Middlesex Hospital Medical School Physics Department, for duties concerned mainly with radiotherapy physics—The Secretary, Barnato Joel Laboratories, Middlesex Hospital, London, W.1.

Reader in Mechanical Engineering, and a Reader in Electrical Engineering—The Registrar, Bradford Institute of Technology, Bradford 7.

Research Assistant (honours graduate in botany, agricultural botany or agriculture (crop husbandry)) in Potato Agronomy in the Department of Agriculture—The Secretary, School of Agriculture (University of Nottingham), Sutton Bonnington, Loughborough, Leics.

Senior Lecturer (with a high qualification in chemistry, together with experience of chemical plant, or a qualification in chemical engineering and appropriate experience) in Chemical Technology, and a Senior Lecturer (with a high academic qualification together with research experience) in Chemistry—The Principal, Welsh College of Advanced Technology, Cathays Park, Cardiff.

SCIENTIFIC AND TECHNOLOGICAL MAN-POWER

A COMPARATIVE study of scientific man-power in the public service of Great Britain and selected European countries, including Denmark, France, Germany, the Netherlands, Norway, the U.S.S.R., Sweden and Switzerland, was undertaken by Mr. E. McCrensky[*] primarily to throw light on the management of scientific man-power in the United States. It provides, however, much more than an appropriate background to the survey of the problem of scientific man-power as it presents itself in the United States made by Mr. D. C. Greenwood[†]. Its chapters on the higher education of engineers and its survey of the organization for research in various countries bring to light factors that tend to be overlooked and are highly pertinent to the expansion of technological education in progress in Great Britain, particularly at a time when the structure of the national research organization, and especially that administered by the Department of Scientific and Industrial Research, is under criticism.

The early chapters of Mr. McCrensky's book survey the position and work of scientists in Government service, the methods of attracting to, and retaining, scientists in such careers, the payment for professional public services and the representation of scientists; and in the final chapter he summarizes the administrative methods and training practices he has observed and emphasizes particularly the features which could be applied elsewhere. Much of the material he has collected has not hitherto been published, and it is notable how well British practice stands out in comparison with that elsewhere. Indeed, it would seem that in some respects the Scientific Civil Service in Britain is far ahead of other Western countries and the United States, and that most countries have scarcely grasped the importance of the principles laid down in the Barlow report on scientific staff fifteen years ago for the effective use of scientific man-power.

As Sir Harry Melville points out in a foreword, the problems of handling scientists tend to become similar wherever they are studied, and although the book is concerned primarily with the use of scientists in the service of the State, the problems that arise are interlocked with the conditions that exist elsewhere—in industry, in the public corporations and in the universities. Differentials in salary arrangements and policies, in the opportunities and freedom to organize research work, to discuss scientific problems and the professional encouragement which is given, all play their part in attracting men and women from one sphere to another and in holding them there; and conditions of service in general must be considered in relation to the conditions and opportunities available to the scientist both in his own country and abroad. Apart from this, Mr. McCrensky recognizes the importance both of wise and sympathetic management and the bearing of favourable working conditions on effective scientific activity as on other creative work.

This survey of Mr. McCrensky's firmly dispels the idea that the scientist should be merely 'on tap' and not, where he possesses the requisite administrative ability, 'on top'. Mr. McCrensky recognizes, indeed, the difficulty of securing the essential flexibility and of deciding at what point in a scientific career to encourage positively the development of some understanding of the principles of administration, management policies and skill in handling people; but he believes that the British Civil Service is in the vanguard, not only of the countries of Western Europe but also of the United States, in its concrete attempt to meet this need. He points, as example, to the residential conferences run by the Treasury, lasting about eight days, and attended by about twenty senior scientists, engineers, architects and administrators, selected from different fields so as to secure the maximum of cross-fertilization of ideas.

Effective communication is undoubtedly a key factor in the management of scientists and securing effective co-operation, as indeed the experience of operational research during the Second World War indicates; and the encouragement in such ways of clearer and more personal understanding of the distribution of responsibilities in government could also help to stimulate the readiness of scientists to share such responsibilities and fit them for such posts. Moreover, even more important, it could help to balance that inherent difficulty in recruitment for government service, in which, in contrast to industry, the same fixed salary is offered to the marginal as to the brilliant candidate. Here again the British Scientific Civil Service at its higher levels is regarded as more sensitive to the special needs of those engaged in creative scientific research than those of any other country of Western Europe, and reference is made particularly to the composition of the Civil Service Commission and to the Interdepartmental Scientific Panel, and to the consistent and uniform application of the principle that scientists and their work can only be properly and acceptably evaluated by their peers.

Nevertheless, Mr. McCrensky makes some criticisms. The rate of promotion in Britain is slower than in the United States, although comparing favourably with most West European countries. The stratification among the three classes in the Scientific Civil Service is sharply defined, reflecting to some extent the national education system. Mobility is also limited by the rigid maximum age limit for entry into the scientific officer class, which normally debars individuals more than thirty-one years of age from competing for permanent posts in the Government service. Finally, some stress is laid on the disparity between the salary scales for the highest positions in the scientific class and those in the administrative class.

---

[*] Scientific Manpower in Europe: a Comparative Study of Scientific Manpower in the Public Service of Great Britain and selected European Countries. By Edward McCrensky. Pp. ix+188. (London and New York: Pergamon Press, 1958.) 40*s*. net.

[†] Solving the Scientist Shortage. By David C. Greenwood. Pp. viii+68. (Washington, D.C.: Public Affairs Press, 1958.) 2 dollars.

These criticisms are relevant in considering the expansion of university and technological education in Britain, for they indicate weaknesses which could well be accentuated as expansion proceeds and even partly frustrate its very purpose. European experience generally confirms the importance of leaving the selection and promotion of scientists so far as possible in their own professional hands within the public service, and affording the broadest possible latitude of self-determination of their administrative responsibilities. Again, the status and prestige of scientific organizations in the public service are enhanced and sustained by the continuous contact of their staff with scientists of the highest standing in other sectors of national life, and Mr. McCrensky instances the value of the National Research Committee in France and its participation in the National Scientific Research Centre. France, as well as Norway and Denmark, uses long-term contracts to provide a higher salary-range in compensation for typical service rights and benefits; but the permanence of tenure conferred by a permanent appointment is a distinguishing characteristic of the systems described in this book. The British Scientific Civil Service certainly demonstrates the practicability of pursuing a life-time career in government service under conditions which do not discourage creative scientific work; but the survey points to the need for strong personal leadership at the highest level if a Government personnel system is to meet the needs of scientists and engineers, as well as for the support of representative leading scientists.

As regards payment for professional public service, Mr. McCrensky's survey suggests that generally Civil services need to establish efficient and reliable internal means for collecting and evaluating current information on prevailing salaries for reasonably comparable positions elsewhere as a basis for a sound policy. Modification of national systems based on a rigid complement of positions within each grade is regarded as offering a major opportunity of improvement, and in this connexion he cites the system followed in the Netherlands by the Central Organization for Applied Research and the 'merit' type of promotions used in the British Scientific Civil Service. The contract type of employment used for engineers in Denmark could also be used more frequently, and provision of a differential of pay allowances and additional leave to the higher levels also merit consideration. Sometimes the necessary flexibility in establishing salaries for scientists and engineers can only be gained by separating government scientific activities from the Civil service, as has been done to some extent in Denmark for engineers, for applied research in the Netherlands and for basic and applied research in the National Scientific Research Centre in France.

The establishment of an independent panel of distinguished citizens to advise the government on its pay policy is also suggested as a constructive measure; but it is not clear what advantage this step would offer over the existing interdepartmental scientific panel in Britain. Part of the problem for the scientist is to translate his views and needs into terms of government administration, and this is unlikely to be done better by those who are not his professional colleagues. This is the key problem in the representation of scientists, and Mr. McCrensky thinks that the attention which has been given to it in Britain in the structure of the Civil Service Commission and the Panel is a distinctive mark of the British system and one that is conspicuously missing from other Civil service systems. He notes, however, that the influence of the Commission is limited to recruitment, and that it has little authority for subsequent leadership. Largely, however, this seems again to be a problem in communication, for in modern governments heads of departments and ministries seem to be precluded by their broad scope of functions and responsibilities from understanding precisely the needs and points of view of the scientist or technologist.

Here, accordingly, the problem is linked up with that of education, for clearly it is necessary to-day that those entering on administrative responsibilities should be equipped by training to have some understanding of at least the approach of the scientist or technologist. That is a condition of the efficient use of trained man-power, and in its absence we shall not make full use of the increasing numbers of scientists and technologists now coming from the universities and colleges of technology. Curiously enough, this point is overlooked by Mr. McCrensky, although in considering the higher education of engineers he notes as probably applicable elsewhere the incorporation of humanistic subjects in the curricula of the technological institutions at Delft and Zurich, and the Norwegian policy of training a proportion of engineers abroad as a progressive measure to broaden their cultural background.

It is such suggestions rather than specific recommendations that mark Mr. McCrensky's survey. He notes features that could be considered for adoption or adaptation, but is aware of the danger of attempting to transplant practice or policy from one country to another without regard to differences in traditions and conditions. Consistently, however, he found a wide gap between the identification and full knowledge of major problems in the efficient management of scientists in the public service, and the initiation of action required to alleviate or eliminate such problems.

Mr. Greenwood, in the second book referred to, attributes the shortage of trained man-power in the United States mainly to about a dozen factors, most of which operate also in Great Britain and other countries. The low birth-rate of the 1930's caused a decline in the enrolment in college in the early 1950's. The failure of many talented youths to complete their high school or college courses was due to various causes. Relatively long training periods, shortages of qualified teachers, inadequate facilities and equipment for research and training, current heavy demands for technologists and scientists and the failure of the educational system to anticipate the increasing demand for technologists all contributed to the shortage, as did predictions of a surplus of engineers, the periodical appearance of 'scare' articles, low salaries and the demand for, and response to, technical assistance abroad.

Mr. Greenwood's recommendations for solving the shortage follow surveys of the educational outlook in the United States, which have stressed the importance of not allowing the scale, quality, character and flexibility of American education to lag behind its increasing responsibilities, of the Government demands for scientific and technical man-power, and those of private industry and of professional programmes designed to deal with the situation. They fall into seven groups according to whether they are addressed to industry, to the Federal Government, to educational institutions, to chambers of commerce, to State Governments, to professional bodies or to the general community. Most of them fall into the first two groups ; but of those addressed to industry only about a fifth are concerned specifically with relieving the man-power shortage, the remainder being directed to raising professional standards or qualifications and increasing the efficiency with which scientific man-power is used.

Under the first heading fall recommendations for encouraging participation in professional activities, including the publication of technical papers and attendance at technical meetings and advanced courses. Under the second, besides more attention to providing appropriate conditions for professional work, relieving trained men and women of work which makes no demands on their professional competence is recommended, as well as providing full auxiliary facilities, and the recognition of competence above average. To relieve the shortage more specifically, Mr. Greenwood suggests full use of older scientific personnel of fifty or sixty, who have several years of useful and productive work ahead of them, and the use wherever practicable of skilled handicapped workers, as well as of qualified women. Trained man-power is also conserved considerably by improved methods of management, including the three-shift system to make maximum use of available equipment. Stress is again laid on the importance of an adequate number of technicians, and there should be no compulsory retiring age for engineers and scientists.

Among the recommendations addressed to the Federal Government, the simplification of the administration of secrecy clearance is strongly advocated, and the more realistic classification of secret material. Stress is laid on the translation of Russian technical literature and the value of greater interchange of allied scientists. But for the rest, the recommendations are directed towards providing a scientist as adviser in each Department of State in which science plays a part and ensuring that the use of scientists in work on defence is properly co-ordinated, overlapping eliminated and that scientists in the Armed Forces are used only on duties which demand their professional knowledge and qualifications. Those addressed to educational institutions contain a number which in Britain would properly be addressed to the Government, and it is interesting to note that while special attention to the brilliant and promising student is recommended, Mr. Greenwood also suggests discontinuance of the present practice of spending time and thought on the maladjusted at the expense of the brilliant child. No less forthright is his advocacy of eliminating courses of no real academic value before we produce a generation of well-adjusted ignoramuses—a warning it would be rash to regard as applying solely to the United States.

Other educational recommendations relate to the salaries of teachers, the maintenance of academic standards and the diversion to technical colleges or similar institutions of as many as possible of the 50 per cent of the engineering students in United States universities who at present fail to complete their courses. The suggestions addressed to professional associations appear to be comparatively minor, and urge closer liaison with the universities and colleges and steps to encourage interest in the schools in science and engineering as careers. Those for the general community note the importance of according scientists and technologists adequate status and recognition.

There is thus little that is new in Mr. Greenwood's recommendations, or that has not already been suggested in Britain in such reports as that of the Willis Jackson Committee or that on "Early Leaving". Surprisingly, comparatively little is said about expanding the output of scientists and technologists : the emphasis is all on eliminating the waste of trained man-power, whether by ensuring it is engaged on tasks that demand professional competence or by providing the conditions under which the scientist and technologist can work most effectively. There is likewise a definite emphasis on the early removal from higher educational institutions of students who seem unlikely to complete their courses, and to make the places available for more talented or satisfactory students as early as possible. The emphasis is all on encouraging ability, and especially outstanding ability, rather than bolstering up mediocrity.

There is, on the whole, a striking parallel between Mr. Greenwood's conclusions and the comments in the latest report of the Advisory Council on Scientific Policy on the scientific and engineering man-power situation in Britain. The key to the removal of the shortage remains the supply of teachers of science and mathematics, and no new suggestions are made for dealing with this situation. Both surveys, in fact, point to the imperative need of action here, and give the removal of the particular shortage of science teachers a priority and an urgency which is lacking in the latest White Paper on secondary education in Britain. Nevertheless, that White Paper does recognize the bearing of an adequate supply of technicians and craftsmen on the efficiency with which the nation is able to use its scientists and technologists. But both Mr. Greenwood's survey and that of Mr. McCrensky deserve to be studied by the Minister of Education and the Lord President of the Council, for they point unmistakably to the essential factors which will determine the success or failure of efforts in Britain to increase the supply of scientists and technologists to a level commensurate with the nation's needs, and to ensure that the maximum use is made of the men and women thus trained.

CONCEPTS OF NUCLEAR PHYSICS

Nuclear Structure

By Leonard Eisenbud and Prof. Eugene P. Wigner. (Investigations in Physics, Vol. 8.) Pp. viii + 128. (Princeton, N.J.: Princeton University Press; London: Oxford University Press, 1958.) 25*s*. net.

THERE are surprisingly few up-to-date text-books of theoretical nuclear physics which may be recommended to the final-year honours student or to the postgraduate beginner. Many books have been written containing a wealth of detail both inessential and confusing to the beginner; several which treat particular topics at some length but fail to give any sense of balance; only one or two of the calibre of this one, and these are mostly out of date owing to the speed at which nuclear physics has grown. In the space of a little more than one hundred pages the authors present a clear and balanced account of the whole of low-energy nuclear physics. As one would expect of Prof. E. P. Wigner and Dr. L. Eisenbud, the book is entirely theoretical in its approach, although essentially non-mathematical. That is to say, the authors have dispensed with the usual long-winded accounts, so common in elementary text-books, of the process of acquiring the data on which the interpretation is based. There are some nuclear physicists who will frown at this even to-day: yet even they would not expect to describe the workings of an ammeter during a discourse on the conductivity of metals, or the properties of spectroscopes while expounding the electronic structure of atoms. The techniques of nuclear physics, both experimental and mathematical, can be found elsewhere: here one will find the concepts.

The first three chapters are descriptive, giving the general features of nuclei, their energy systematics and ground-state properties. As an illustration of how up to date the book is, one notes that the values quoted for nuclear radii are those recently obtained by Hofstadter using the scattering of high-energy electrons. The fourth chapter gives a correspondingly descriptive account of the various types of nuclear reactions. At the end of this chapter occurs about the only reference to practical matters, in the delightfully succinct sentence: "Nuclear reactions can be used to produce radioactive elements". The fifth chapter gives a brief account of the properties of the two-body system and of nuclear forces. Here again one finds a modern picture, with Levy's potential, complete with hard core, appearing in the most unembarrassing fashion. The three following chapters are concerned with the various models which have been put forward to try to understand nuclear properties. Only the essential assumptions and most significant results of each model are discussed, and the relations between them. There follow two chapters on the theory of nuclear reactions, the first of which gives a beautiful and almost painless account of the powerful *R*-matrix theory (or rather of its essential concepts, for it is only the details which are gruesome and these are omitted, in keeping with the rest of the book), the second an account of stripping reactions and Coulomb excitations. Resonance formulæ, reduced widths, radioactivity, complex potentials, giant resonances—they are all included within a very few pages, without fuss, and yet, somehow, with sufficient explanation to make one feel one really understands it all. The final two chapters deal with beta-decay and with electromagnetic transitions. Here, unfortunately, the book is already obsolete: scalar and tensor reign supreme and parity goes inviolate. A most valuable addition is the list of carefully selected references, which are commented upon by the authors so that an inexperienced reader can easily find his way to the vast modern literature.

The critical reader may certainly find some faults. There seem to be one or two misprints, and it is a pity that the word 'Fermi' has been introduced as a synonym for 'barn'. Although the usage is historically correct, the Fermi is now almost fully established as the nuclear unit of length. One may wonder why the *LS*- and *jj*-coupling models are presented in such contrasting tones: most people to-day would regard them as extremes of a very narrow band of colours. But these are quibbles. It is an excellent little book, warmly to be recommended to anyone who wishes to obtain an authoritative and balanced view of the concepts of nuclear physics. Even the price is a welcome surprise. B. H. FLOWERS

FLUID SYSTEMS IN CHEMICAL ENGINEERING

Chemical Engineering Practice

Edited by Herbert W. Cremer and Trefor Davies. Vol. 5: Fluid Systems I. Pp. vi + 695 + xxiv. (London: Butterworths Scientific Publications; New York: Academic Press, Inc., 1958.) 95*s*.; 13.30 dollars.

THERE is probably no aspect of chemical engineering that has received greater attention, and which so clearly indicates the special nature of this technology, than that of distillation. In the petroleum industry the installed capacity for distillation is greater than that for any other operation, and the modern petrochemical industry as well as the conventional organic chemical industry are wide users of distillation equipment. A large section of this volume is taken up with an account of the techniques of, and equipment for, distillation, and for this reason alone this work will receive much attention. The allied operation of liquid – liquid extraction is also covered, so that we have here an exposition of two of the really important chemical engineering operations which have been widely developed by chemical engineers. There are other important sections which will prove of considerable value not only to the professional chemical engineer but also to that wider body of engineers whose work brings them to chemical engineering from time to time. The main topics discussed are transportation of liquids and gases, the design of high-pressure vessels, the production of vacuum, liquid – liquid stage-wise operation, and distillation.

In the first chapter, Hey gives a summary of the types of pump available for handling liquids, including an adequate account of their construction and maintenance, and a very useful note on methods of controlling flow. One might have expected something on the newer types, such as electromagnetics, and some greater detail on the important class of metering pumps.

The next section, on the transport of gases, by Messrs. Barrett, Jackson and Brown from Imperial Chemical Industries, Ltd., contains a most readable discussion on blowers, fans and compressors, and is improved by having two examples worked out. Williamson, also from Imperial Chemical Industries, Ltd., provides a really practical guide to the design of pipe systems, in which he has condensed much practical experience in a chapter on a topic not previously discussed in the literature.

The design of high-pressure equipment is covered by Prof. D. M. Newitt and Mr. K. E. Bett, of the Imperial College of Science and Technology, London. The difficulties of creep, of high temperature, of gaseous diffusion, and of embrittlement are well brought out and the various methods for design and construction are described. They give a large number of references which are helpful; but work in this field calls for specialization for the few, and this chapter serves rather to underline the problems as seen by chemical engineers than to provide detailed design solutions which are more properly the province of mechanical engineering. One would like to have seen something on the heavy cost per unit volume of reactors for very high pressures.

Section 5, by Barrett and Power, from the Edwards High Vacuum Company, provides a good account of the selection of equipment for this duty. While there is some repetition of earlier work on fluid friction, the real problems of flow at very low pressures are well explained with one or two illustrations.

Almost the whole of the second part of the book is devoted to the operations of liquid – liquid extraction and of distillation. Prof. F. H. Garner and his colleagues from Birmingham first describe the nature of the phase equilibrium in liquid – liquid systems both for ternary and multicomponent systems and then outline the calculations required to determine the number of stage-wise units required. The section on selectivity of the solvent is perhaps the most interesting, and the illustrations of the use of the triangular and rectangular co-ordinate diagrams will help many readers. The examples given here are both well chosen and well presented.

In a somewhat parallel chapter, Prof. S. R. M. Ellis describes the calculations of the stages required for a distillation operation. He gives all the normal methods and illustrates them with good examples. He has provided a useful analysis of the batch still, a subject too frequently neglected.

The section on equipment for both operations is by Dr. Freshwater, and, although he describes the problems of entrainment, capacity and pressure-drop, one is left a little wondering if it all fits together. One really good example from practice would have brought out the order of magnitude of the various terms and left a clearer idea of the operating conditions. The use of computers for the calculation of changes in composition in stills with multicomponent systems is not indicated, and little is said as to the range of temperature and pressure for which the design techniques are satisfactory. The problem of handling widely different ratios of liquids and gases is not emphasized.

This volume catches the spirit of chemical engineering; there is no doubt one is dealing with real chemical plant. This is a good text which will be used by many.

J. M. COULSON

INTELLIGENCE, FAMILY BACKGROUND AND EDUCATIONAL PROGRESS IN SCOTLAND

Eleven-Year-Olds Grow Up

By John S. Macpherson. (Publications of the Scottish Council for Research in Education, No. 42.) Pp. xxiii+184. (London: University of London Press, 1958.) 15s. net.

THE Scottish Council for Research in Education here presents the first report on the information it has been collecting since 1947 concerning the educational and vocational progress of some 2,000 children born in Scotland in 1936. This group of children is a representative sample of all those born in that year; it is, as the report suggests, a "Scotland in miniature", "ranging over the whole scale of intelligence, born in every month of the year, from different social classes, from Lowlands, Highlands and Islands, from village, city and town, from large families and small". The report describes what has happened to this Scottish sample between 1947, when the last mental survey of the whole age-group was undertaken, and 1954, by which time practically all had left school and chosen or embarked on their first occupation. Many matters of interest and importance are dealt with; the effect of parental ambitions and sex differences on occupational choice, relationships between the occupations of sons and fathers, change of occupations, the attitudes of young workers to further part-time education, the leisure interests of young people and the attitudes of boys to National Service.

The report hinges, however, on the examination of the relation between measured intelligence at the age of eleven, and the subsequent educational and vocational progress of the pupils in the sample. It is, in fact, a description in some detail of the process of educational and occupational selection in Scotland, as reflected in the experiences of the age-group of children who entered secondary schools two years after the Second World War. The two questions of interest are the value of measured intelligence at the age of eleven as a predicter of future academic and vocational achievement, and the possible biasing influence of extraneous social factors on the process of educational and occupational selection whereby talent should find its own level.

So far as the predictive value of measured intelligence is concerned, the report makes it clear that this is limited to estimating for a group of pupils the proportion likely to be successful in following a particular school course or class of occupation, but that it would be impossible to predict on this basis alone the individual pupils who would go to make up the successful group. However, one further piece of information about each child involved makes it possible to predict relative chances at least one degree more accurately, and that is the father's occupation.

Social factors are strongly at work in the process of educational selection. The report under review, like that of the Central Advisory Council for Education in England ("Early Leaving", H.M. Stationery Office; 1954), although in a technically more refined manner, shows a relationship in the selective secondary school between the father's occupational class and a child's chances of completing the course and proceeding to advanced work which is practically independent of intelligence quotient (*IQ*). Thus, in the Scottish sample, for able boys with an *IQ* greater than 120 coming from working-class families (namely, those whose fathers are manual workers) the chances of completing the course are about 2 in 5; but for similarly able boys from other (that is to say, non-manual) families, the chances are about 2 in 3. For those with an *IQ* less than 120 there is the same difference in chances according to social background; for working-class boys at this level of ability they are about 1 in 5, but for others 1 in 2. However, the Scottish report explores the implications of this striking finding much less thoroughly and imaginatively than the English report. Related findings, such as that early leavers tend to be deficient in personal qualities such as industry, or had very difficult home circumstances, or did not find the course interesting or useful for the career they had in mind, or were known not to be succeeding in the course for other known or unknown reasons, are accepted at their face-value as psychological irreducibles. The English report, on the other hand, examines the possibility that those factors are systematically related to sociological variables such as father's occupation, size and sex of the school, or the social and economic character of the neighbourhood in which it is situated. Clearly these are the lines, sociological rather than psychological, on which further work on the problems of educational selection and performance must proceed. JEAN FLOUD

CRITIQUE OF WITTGENSTEIN'S PHILOSOPHY

The Later Philosophy of Wittgenstein

A Short Introduction, with an Epilogue on John Wisdom. By Dr. David Pole. Pp. vi+132. (London: The Athlone Press, University of London, 1958. Distributed by Constable and Co., Ltd.) 15*s*. net.

IN this book, small in size but weighty in learning, Dr. D. Pole sets out to be an interpreter and, in part, critic of Wittgenstein's later thought as expressed in his posthumous writings. Appropriately enough, a chapter is included on the work of Prof. Wisdom, whose method is characteristically British, though he has done much to graft it on (and this is in itself no mean achievement) to the Germanic, and even Hegelian strain running through Wittgenstein.

These essays begin with a discussion of the linguistic approach to philosophy, followed by some detailed observations upon logic and normative language, together with the place of inner experience. The main theme is rounded off by a consideration of the difficulties in Wittgenstein's philosophy. In all this, one cannot be blind to the immense change which came over Wittgenstein since he first startled the learned world with the "Tractatus" in 1922.

A favourite illustration is that of a machine running idle, or of a wheel spinning freely without engaging with the rest of the machinery. Such a mental situation derives from forgetting that language is something which we inherit, whereas a calculus is a deliberate construct. Noteworthy, too, is the view that for Wittgenstein a mathematician is more an inventor than a discoverer.

Yet Wittgenstein, himself no professional mathematician, helped that discipline substantially in several ways, not least by the realization that "in working with shapes, we create our concepts".

Perhaps it is hereabouts that Wittgenstein makes an incidental contribution of importance to psychology in throwing up, as it were, the nature of boundaries as perceived in geometric figures. This is common ground for *Gestalt-theorie*, behaviourism, and even for parts of isomorphism. Some of these may be out of fashion but they are part of man's heritage, and Dr. Pole has done well to include hints of them in his valuable study. F. I. G. RAWLINS

THE CLERK IN INDUSTRY

The Blackcoated Worker

A Study in Class Consciousness. By David Lockwood. (Studies in Society.) Pp. 224. (London: George Allen and Unwin, Ltd., 1958.) 21*s*. net.

THE position of the clerk in industry and commerce has changed considerably during the past forty years. Before the First World War the clerk commanded authority and respect *vis-a-vis* the manual worker. Because of his closeness to the employer he was paid more, was treated as a person of considerable status both because of his knowledge of the company's secrets and because of his literacy, and often succeeded to posts of management responsibility because of his experience in administration. Now, as David Lockwood shows in a scholarly, well-planned and carefully written investigation, the clerk's position is generally very different.

In the days of the counting-house, clerks were nearly all male and were recruited from middle-class families, frequently from the homes of clerks themselves. To-day, much of the work in a mechanized office is done by females, many of whom—as well as their male counterparts—are recruited from the lower social strata. Up to 1914 the ordinary adult clerk earned roughly the same as a skilled manual worker. In 1958 even the aristocracy of blackcoated labour—the banking and insurance clerks—no longer enjoy an economic status clearly distinct from the wage-earning classes; the mass of clerks are roughly on the same income-level as the average manual worker. The clerk's position is also changing relative to that of the manual worker with regard both to job security and 'fringe' benefits.

These are some of the generalizations which emerge from factual information so painstakingly gathered and sifted by the author. They reinforce the experiences of all who are concerned with the place of the clerk in industry and commerce and should illuminate the implication of modern trends. Reduced pay differentials, greater job insecurity and the difficulty of finding other jobs when declared redundant, as well as lessened chances of promotion with the introduction of management trainees, are some of the factors combining to make the clerk's position more unstable. As a consequence, many firms are already finding it difficult to recruit sufficient clerks of the right quality. Lockwood's book should be read by all employers who are faced with this problem and are prepared to tackle it before it becomes too unwieldy.

A NEW SOLUTION TO THE ATLANTIC EEL PROBLEM

By Dr. DENYS W. TUCKER
British Museum (Natural History)

TWO nominal species of Atlantic eel (*Anguilla*) are currently recognized, mainly distinguished by their myomere/vertebra counts. *A. rostrata* (Le Sueur) of North America has 103–111 vertebræ (mode 107); *A. anguilla* L. of Europe and North Africa has 110–119 (mode 115). These two eels are more closely allied in every respect than either is to any other[1]; the remaining discriminating characters comprise small differences in mean numbers of branchiostegals (11·03 : 10·78), pectoral rays (16·73 : 17·37), etc., and minor differences of body-form of no greater importance than those formerly held to justify the recognition of a dozen European 'species'[2]. Both include 'long-nosed' and 'broad-nosed' varieties; both have a sexual disparity of size. Their larvæ "are outwardly so alike as to be hardly distinguishable"[3].

Two thousand years of speculation on the life-history of the European eel[2] culminated in the classic solution of Schmidt[3,4], a well-publicized saga which scarcely requires detailed repetition. Schmidt, sorting the *A. rostrata* and *A. anguilla* leptocephalus larvæ on their myomere counts, laboriously plotted the limits of distribution of larvæ of various lengths (Fig. 1) and so eventually traced their apparent origins to two supposedly distinct, though partially overlapping, areas in the region of the Sargasso Sea which were presumed to embrace the actual spawning-areas. The last was an assumption based on circumstantial evidence; eggs were never found, and, for those who disallow the careful claim of Fish[5], denied by Schmidt[6] and by Tåning[7], never have been. Furthermore, the *A. rostrata* prelarvæ have yet to be found; *Anguilla* adults have yet to be taken in the open ocean (one from the stomach of a cachalot off the Azores[8] is obviously suspect of local provenance); naturally ripe eels in full breeding-dress (as demonstrated by hormone-injection experiments[9]) have yet to be observed. However, Schmidt did demonstrate the fact of an oceanic spawning and show conclusively that the American eels complete their pelagic stages in one year, whereas the European ones require three years before they enter the inshore waters of their respective continents.

Schmidt's now generally accepted solution demands, not only a long journey on the part of the nearest

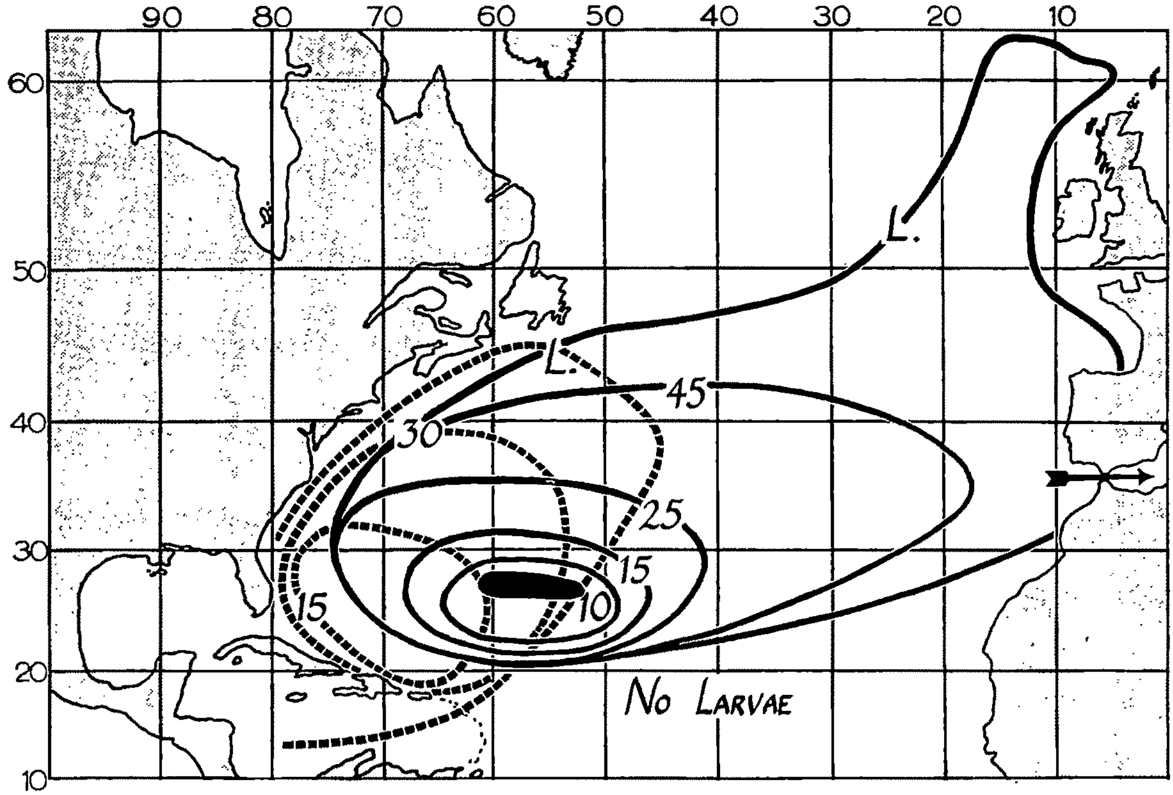

Fig. 1. Distribution of Atlantic *Anguilla* larvæ. ——, *A. anguilla*; – – –, *A. rostrata*. The curves show the limits of occurrence of larvæ of the indicated mm. lengths. The black area shows the distribution of newly hatched (5–7 mm.) *A. anguilla* prelarvæ. Curves *L* mark the limits for unmetamorphosed larvæ. (After Schmidt, refs. 3 and 4)

American eels returning to their spawning area, but a much longer one, of the order of at least 3,500 miles on a great circle course, by the European eels. The present article rejects the latter assumption and proposes a new and drastically different interpretation of the observed phenomena, namely :

(1) That the European eels need not and do not succeed in returning to the ancestral spawning-area, but perish in their own continental waters.

(2) That the American and European eels are not distinct species, but merely eco-phenotypes of *Anguilla anguilla*, their apparent distinguishing characters being environmentally determined (in the manner of numerous precedents) by demonstrable differences in temperature conditions encountered during the ascent from different parts of the American eels' spawning area to the surface, and their distribution by demonstrable coincident differences in the subsequent transport of the surface water-masses.

(3) That the populations of the so-called 'European' eels, *A. anguilla*, are therefore entirely maintained by reinforcements of larvæ of American '*A. rostrata*' parentage.

The evidence and arguments are presented under three broadly corresponding headings.

(1) Evidence against the Return of the European Eel to the Spawning Area

Differences between the morphological and physiological states of the European and American eels on their descent to the sea are remarkable in a context quite apart from taxonomy. The European eel is already well advanced towards being a reproductive oceanic fish, and this despite the long journey which supposedly lies before it. The American eel, with a much smaller distance/time to go, is yet relatively retarded. The two conditions are the reverse of what any reasonable consideration of adaptive characters and natural selection would predict.

The American eel[10], on average a larger and four times heavier fish than the European (females, 56 : 14 oz.), descends to the sea as a 'bronze' or 'black' eel, in a migration livery which is little more than a darkening of the normal colour accompanied by metallic reflexions. Fat has accumulated to about one-third of the total body-weight ; feeding has ceased and the gut begun to degenerate. The gonad has been scarcely studied, but there is certainly no enlargement of the eye, no change from the normal short, rounded form of the pectoral fin, no blocking of the vent nor any assumption of silver coloration[10]. Its condition thus approximates to that of the 'yellow' eel of Europe.

The European eel[2] descends as the well-known 'silver' eel, having a broad band of guanine running the length of its belly. Along with a profound degeneration of the gut and perceptible enlargement of the gonads, there is marked enlargement of the sense-organs ; the eyes, in particular, double their diameter[10,11], though without increasing the number of retinal elements[12] which were previously intensely crowded behind a contractile pupil[13]. The pectoral fin becomes lengthened, lanceolate and black[10,11]. One apparently normal (that is, non-pathological) fish from the North Sea showed complete occlusion of the vent[14]. In very few examples (*post*) has any more advanced gonadial condition been observed in Nature. We have, therefore, in the typical case, a fish degenerate and unable to feed, having a fat reserve which must provide for the maturation and vast enlargement of the gonads as well as for the propulsion of the enfeebled body on a presumed 3,500-mile journey. Instances of longevity in eels (fed or starved) in captivity[2,10,15] are irrelevant to this problem, since their normal physiological modification had, in every case, ceased or regressed after capture.

The European eel shows positive reactions to higher temperature and salinity ; negative ones to solid bodies and to light[2]. Agreed that all *A. anguilla* are derived by passive dispersal from one breeding area, there can be only one common inherited pattern of behaviour, yet this has hitherto been assumed adequate to direct the return journeys of eels leaving points all over Europe and North Africa and successfully traversing a great variety of conditions to a common oceanic terminal. Any lingering resistance to the new hypothesis may be dispelled by a study of Sverdrup *et al.*[16] considering, for example, the complexly involuted current/temperature/salinity conditions in the inner Mediterranean, the flow of Mediterranean water through the Atlantic, the north-going Norwegian Coastal Current which leaves the Baltic and heads for the Arctic, and the complicated counter-clockwise circulation of the North Sea. How could eels regularly negotiate such systems and end up in the western tropical Atlantic ? Furthermore, while theories demanding either passive transport by currents alone or active response to gradients alone are inadequate, since many of the currents are of the order of a mile a day and many of the gradients gradual over vast areas of ocean, theories involving both must, under European conditions, obviously contain a large degree of self-contradiction (Fig. 2). There can be only one inherited pattern of behaviour ; therefore, moreover, a hypothetical pattern of complicated and successive changes of behaviour which might take a Baltic eel via the Azores or via Jan Mayen to the Sargasso would serve no purpose to one leaving the Black Sea.

Marking experiments have proved the passage of eels along the Baltic[17] ; eels have been captured rarely at the mouth of the English Channel[18,19] ; the exodus has been observed at many points around the Mediterranean[20,21]. But these cases provide proof only of local short-range migrations. The eels, if they survived, would be abundant. Why have they never been taken by research vessels in the open Atlantic or by the intensive fisheries along the Continental Slope ? Are agility and this or that depth of swimming adequate explanations ? The expected passage of the vast Mediterranean populations through

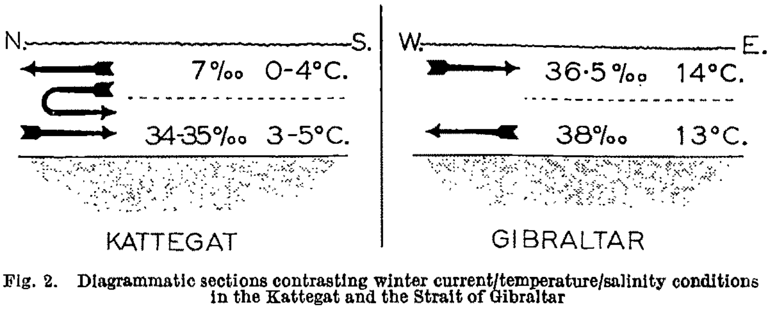

Fig. 2. Diagrammatic sections contrasting winter current/temperature/salinity conditions in the Kattegat and the Strait of Gibraltar

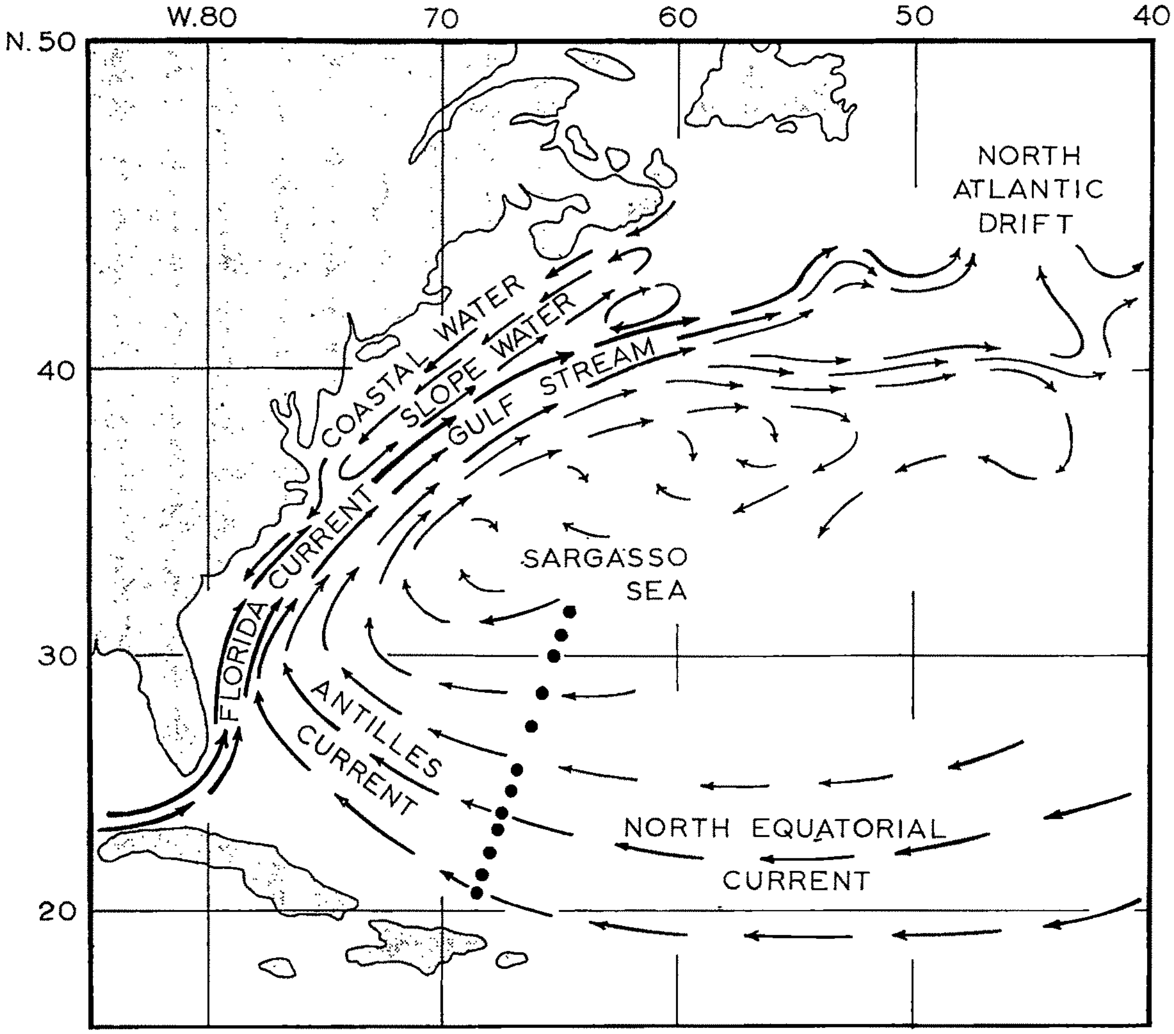

Fig. 3. Atlantic surface currents affecting the distribution of *Anguilla* larvæ. The map also indicates the positions (● ●) of the *Atlantis* stations involved in Fig. 4. (Adapted, after Sverdrup *et al.*, ref. 16, and Iselin, ref. 34)

the sharp focus provided by the Strait of Gibraltar has never been witnessed, despite much study; indeed, Ekman[22] has anticipated me in denying that it occurs, which is already tantamount to saying that the Mediterranean stocks at least are maintained by breeding populations from elsewhere. Quite apart from the difficulties of navigation, it may well be that the distances from the great Mediterranean river-mouths to Gibraltar are already beyond the eels' capabilities.

Supporting evidence comes from another direction. There is a substantial uniformity of condition and unanimity of action in the departure of the eels from the rivers[2]. Yet from time to time isolated individuals are found in adjacent seas in advanced conditions of ripeness; in the Baltic[23], English Channel[19] and Mediterranean[20]. These isolated individuals may be the last survivors of stocks which have migrated from much farther east. Heavy eel-mortalities have been observed even in the Mediterranean[20]; elsewhere, "In consequence of excessively stormy weather this month (Feb. 1655) many thousands of dead eels were cast out upon the banks of the North Loch at Edinburgh, to the admiration of many"[24].

In the Mediterranean, again, are several deeps which offer conditions apparently identical to those of the Sargasso, yet eels do not spawn in them nor anywhere in that Sea[25]. In the open Atlantic the Cape Verde Basin, Monaco Deep and West Indian Basin, all on the obvious migration route, are likewise devoid of young larvæ.

Explanations of the hypothetical long-range migration in the open ocean have ranged from notions of voluntary point-to-point navigations to the idea that the eels first passively ride the Canary Current and are afterwards carried in the North Equatorial Current[26]. A proper scepticism towards all these suggestions has hitherto been inhibited by the inescapable fact of the Sargasso larvæ. Speculation has gone as far as "Les Amours des Anguilles"; the parting words of a legendary watcher by the Rhine may now seem more appropriate[27]: "Ihrem Ende eilen sie zu, die so stark im Bestehen sich wähnen".

The east-coast American migration, by contrast, presents little difficulty. Along that coast the coastal water and immediately adjacent slope water are moving in a south-westerly direction (Fig. 3). Recent *Discovery II* work[28] has confirmed the hypothesis

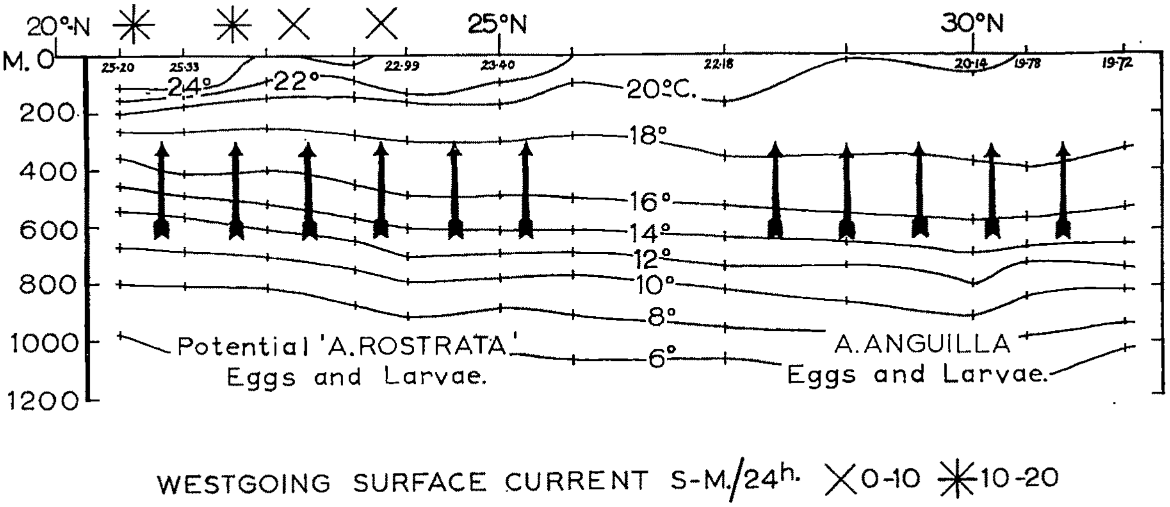

Fig. 4. Section across the *Anguilla* spawning area. Isotherms after Iselin (ref. 34) based on *Atlantis* stations 1208–1219, Haiti to Bermuda, April 7–13, 1932. Surface-current velocities for March inserted after Dietrich (ref. 36)

of Stommel and proved the existence, 150 miles off South Carolina, of a strong south-going current (up to 8½ miles a day) deep under the Gulf Stream. This system provides a simple, rapid and direct path, and without demanding any differences of behaviour among the different eastern groups of American eels. Temperature and salinity gradients encountered on this route[16] are such that active migration would reinforce passive transport. The fate of the Mississippi eels need not concern us.

We may here meet Bertin's demand[2] for a migration theory containing all the observed phenomena of physiology and behaviour. The evidence shows that the debility of the (European) eel which is obliged to drift passively downstream in the current is due to demineralization of the starving body at the inception of gonadial and other hormone activity, and that re-mineralization and resumed liveliness occur when the eel reaches the sea[2,29]. (The survival of silver eels captured and imprisoned in fresh water[15] shows that with gonad-regression continued life is still possible, that is, through re-mineralization accomplished at the expense of the gonad, so that in the early stages the process is reversible.) Thus far no voluntary activity is called for.

With continuing gonadial activity, further demineralization occurs which can only be remedied under conditions of higher ambient salinity. The eel experiences a malaise alleviated by migration towards higher salinity and aggravated by passage into lower-salinity waters; here is the mechanism of the observed halotaxis. Failure to migrate leads, by this stage, to increasing mineral unbalance and to death. The better-adapted American eels migrate until they are trapped in the warmest, deepest part of the North Atlantic Central Water under the Sargasso, in a salinity of $35^{0}/_{00}$–$36^{0}/_{00}$, where the climactic stages of gonadial maturation, de-mineralization and spawning occur. Death after spawning may be assumed; European males experimentally ripened and spawned died within 12–24 hr. of emission[9], while *Conger conger* is known to become more debilitated after spawning[30,31] than any *Anguilla* yet observed.

The reproductive metabolism is clearly geared to the need to produce gametes which will be isotonic or hypertonic to the water in which they are spawned; that metabolism in turn imposes the selection of spawning area. If, as is very likely, many forced spawnings occur short of the Sargasso, unfavourable osmotic and temperature conditions would speedily efface the evidence.

(2) Evidence concerning Possible Temperature Effects and Transport of Eel Larvæ

A substantial body of evidence[32] shows that vertebral numbers in fish populations are inversely correlated with ambient temperatures. Experimental studies, for example, on *Salmo trutta*[33], of effects of temperature in ontogeny, have shown that there is also a supersensitive period in the development of the egg during which a temperature change may have a shock-effect; means of 56·86 and 60·06 vertebræ were obtained in batches of young from the same parents, a difference proportionally similar to that pertaining between whole populations of Atlantic *Anguilla*. Other meristic characters, such as numbers of rays in median and paired fins, are likewise affected[33], not necessarily at the same time or in the same direction.

If we may assume that *Anguilla* shares the common susceptibility to such factors, hydrological data are available to show how phenotypic differentiation may occur.

Consider the rectangle between 20–30° N., 50–70° W. The surface-current system in this region (Fig. 3) comprises the west-flowing North Equatorial Current with its north-westerly continuation, the Antilles Current. Conditions are substantially similar throughout the moving water-mass just defined[34]; any section normal to the direction of flow provides a fair picture of the whole, wherefore the section Haiti–Bermuda given by *Atlantis* Stations 1208–1219[34] may be taken as a basis for discussion of conditions over the eel spawning area (Fig. 4).

Assume a linear spawning area extending from 20–30° N. and at a depth (400–700 m.) below the influence of surface currents. Eel eggs, rising through the lower layers, will encounter a substantially identical temperature gradient until they strike the 18° C. isotherm at about 300 m. From then on several conditions become differentiated simultaneously, roughly in relation to latitude.

Eggs and larvæ at the southern limit pass through the gradient 18–25° C. during the last 250 m. ascent; in particular, they encounter an abrupt 4° rise between 200 and 100 m. which may well have the effect of ending segmentation and so fixing the number of somites/vertebræ in the range 103–111 recognized as typifying '*Anguilla rostrata*'.

At the northern limit, however, the temperature gradient remains gradual right up to the surface, where a maximum temperature of barely 20° C. is encountered. No temperature effect, certainly no shock effect, is likely, wherefore the addition of somites presumably continues to the genetically determined limit and results in the population with 110–119 somites/vertebræ which we recognize as *A. anguilla*.

Further biological effects may be assumed. First, in the '*A. rostrata*' larvæ, the higher ambient temperatures must result in a higher metabolic rate, supported by the higher zooplankton concentrations along their route[35], hence the higher growth-rate and, probably, the shorter larval life; duration of life and growth-rate in the adult have not been studied but may also be affected by the extreme conditions of this earlier phase. For the *A. anguilla* population the converse assumption and observations hold.

Secondly, as in any such system, the Antilles Current runs deeper[16] as well as faster[36] at its periphery. This means that the '*A. rostrata*' larvæ begin to be transported westwards while still at a considerable depth; for the *A. anguilla* larvæ such lateral movement does not commence until they approach the surface, and even then is much slower than in the other case. Consequently our original north–south linear spawning area produces, some weeks after spawning, a surface population of larvæ which lie along a line more or less skewed from north-east to south-west. A spawning-area pattern of any shape or size, lying between the prescribed limits, will be similarly transferred when the resulting larvæ approach the surface.

It will be observed that the zone of *A. anguilla* prelarvæ mapped by Schmidt (Fig. 1) tallies with the hypothesis raised in relation to Fig. 4, and there can be no reason for doubting, from the abundance of stations worked and from our knowledge of the hydrological conditions, that this is the spawning area for this section of the *Anguilla* population. The concentric contours of the early stages are likewise compatible with slow migration at random over an area of weak surface currents.

Schmidt's postulate of a distinct '*A. rostrata*' spawning area to the south-west appears invalid. We are given the limit for larvæ of 15 mm., which, at a moderate estimate, must be a month old; resting in a current system travelling at 10–20 miles a day they must be at least 300–600 miles from their point of hatching and up to twice as far from the spawning area. Considered in relation to the Antilles Current, it is evident that the distribution is not compatible with a source lying within the 15-mm. contour. The 15-mm. contour must enclose the surface, the oblique section, of a solid cone of larvæ of diminishing age the truncated vertex (the spawning area) of which lies deeply embedded very much farther back in the current, practically due south of the *A. anguilla* area and contiguous with it. Geographically there is probably only one spawning area altogether, of which the mass of resulting larvæ becomes obliquely and sharply divided and differentiated by the sheer of the sharply defined current. This analysis removes the need for belief in a critical discrimination of spawning areas by adults of two species, related to micro-isotherms[8], bottom topography or some other biologically improbable factor.

In fairness to Schmidt, it must be said that he lacked much of the information now available and that his terms of reference from his Government were to locate the birthplace of the European eel. The '*A. rostrata*' larvæ were, to him, an unexpected nuisance. In the area now suggested as the source of the '*A. rostrata*' phenotypes the Danish Expeditions took only a score of stations[37]; those of the R.V. *Margrethe* were worked in during November–December 1913, too late in the year, while the remainder, at miscellaneous dates and shallow depths, were worked by amateurs from commercial vessels, in a region of rapid currents and, on my hypothesis, minute deep-lying prelarvæ. Closing nets were not used.

It may be objected that '*A. rostrata*' is said to breed during January–February, *A. anguilla* during February–March[3,7]. Against this simple statement must be balanced the fortunes of collecting, the lengths of overall journeys from various starting-points, disparities in sexual maturation, velocities of currents at various possible migration-depths, durations of spawning periods and annual variations in all these; effects of temperature on rates of hatching and early development and rates of ascent of larvæ over different parts of the spawning area. The criticism is more easily answered than made.

'*A. rostrata*' larvæ reach their limit of 60–65 mm. in about nine months and metamorphose into 'glass eels'[3]. Many, still travelling on the periphery of the Gulf Stream system, lie along the North American coast which they approach as pigmented elvers the next spring, a year after hatching. Some laggards colonize brackish ponds in Bermuda[38]; vast numbers of *A. anguilla* all by-pass that island.

A. anguilla larvæ travel mainly on the inside of the current system (some being trapped for a year or more in the Sargasso[3]) so that large numbers travel east and north-east across the Atlantic. Metamorphosis occurs off the edge of the Continental Shelf, except in larvæ which penetrate the Mediterranean to beyond the heel of Italy. Lower temperatures and metabolic rates prolong the pelagic phases to three years and extend the limit of growth to 75 mm.[3].

Environmental conditions affecting metamorphosis have been little studied. The limits of successful larvæ of both groups coincide with the spring surface isotherm for 8° C., which marks the margin of the Gulf Stream system and coincides with the edges of the Continental Shelves, but there are many complicating factors to be considered: turbidity of inshore waters, lateral mixing with lowering of temperature and increased oxygenation, upwelling of cold water at the edges of the slopes (and off Bermuda ?) and possible changes in salinity relations which would affect the hydration observed at metamorphosis. The situation is too complex for theoretical consideration.

It is, however, certain that thyroid secretion is important at metamorphosis; Murr and Sklower[39] have shown that in the late leptocephalus the thyroid increases to ten times its previous size and regresses again in the glass eel. This mechanism must ultimately be under genetic control (modified by ambient temperatures through metabolic rates); '*A. rostrata*' in mid-Atlantic and *A. anguilla* in the tropical Atlantic normally perish without making landfall and metamorphosis is delayed only for part of the Mediterranean transit. In both, therefore, whether forms or species, the hormone regulatory system must act ultimately regardless of unfavourable environmental conditions; we shall need this point again later.

The proposition of Schmidt[3] (p. 204, lines 20–40: "How do the masses of larvæ in the Western Atlantic sort themselves out . . . ?") has led to misunderstanding, especially among lay authors. The situation is, that of the mixed aggregations of larvæ, those which make landfall too soon, too late, or not at all are doomed to perish; the former because their hormone mechanism cannot be triggered early enough by environmental conditions, the latter because the same mechanism decrees that metamorphosis can no longer be delayed. The process is not a sorting, but rather an elimination, of the mis-directed and consequently ill-adapted.

(3) Implications of the New Hypothesis

As a syllogism, the new hypothesis may at least claim parity with Schmidt's, since both theories provide an explanation for the origin of the European eel larvæ and both make a single unsubstantiated assumption. As a biological proposition, however, the probability of the assumed effect of temperature, with its numerous precedents, may be considered more reasonable than that of a 3,500-mile directive migration for which there is no parallel among fishes.

The differentiation of *A. anguilla*/'*A. rostrata*' phenotypes is shown to be credible without genetic intervention; the need for a return migration by European eels to the Sargasso has been removed, so that this problem may be considered divorced from any assumption that it must occur; and we are left with the implication, seemingly more likely and no less remarkable, that Europe and North Africa are regularly colonized by eels of American ancestry doomed to perish in a fruitless suicide-migration.

It remains to provide an explanation of the physiology of the European eel. We know that males attain the age of 7–12 years, females 9–19 years in fresh water[2]; we also know authenticated cases of eels in captivity attaining an age up to 88 years under conditions in which sexual maturation was suppressed[10,15]. The disparity is remarkable; many cases are known of the antagonism between growth and reproductive metabolism, and of animals which breed once and then die; but there is surely no parallel to this. The desperate rapacity of the eel is well known; moreover, Bertin[2] shows that growth-rates vary enormously in different European rivers, evidently in relation to size of water and available supply of food. From this evidence and from considecations of early larval life an explanation can be drawn.

Migration and sexual maturation in *Anguilla* are controlled by a hormone system—hypophysial[40], thyroidean[41] and gonadial[42]—which is certainly genetically determined and, by my hypothesis, preconditioned by early environment. Growth in length appears to be genetically limited[10,43], but growth in bulk is subject to external environmental conditions of temperature, living-space and supply of food. Under American conditions (fishery statistics[10] almost permit us to say St. Lawrence and Great Lakes conditions) of higher ambient temperatures in the larval stages, larger rivers and better supplies of food throughout life, the predetermined sexual maturation and environmentally determined growth-metabolism are synchronized in a viable life-cycle. Under less-favourable European conditions, the predetermined hormone system functions prematurely, and the mechanism of sexual maturation is invoked before the body can sustain its consequences. We have already seen this hormone system in action under unfavourable conditions in mid-Atlantic larvæ; if it can act catastrophically at the first metamorphosis it can surely do so at the second? The disparities in mean weights of American and European eels point to this view, as do the longer stays of the females, the gonads of which have, under optimum conditions, to accumulate greater resources of food. The disparities between American and European eels on their departure likewise fit the picture; the European eel delays to the last possible moment and the migration livery appears before the still premature (and unnecessarily premature) migration is invoked. Environment may advance migration activity a little (in the American eel) or retard it (in the European), but outside the permitted range of variation, in the adult as in the larva, there can be no modification of an inexorable predetermined system.

Since selection pressure upon the Atlantic *Anguilla* acts only in relation to American conditions there is no means by which the deadlock of the 'European' eels can be broken; they represent, in perpetuity, the waste of a major part of the American eels' breeding-potential, compensated for by the adequate numbers of the latter and the ten million or so eggs[10] which a female can produce.

Conditions for the proof of either hypothesis are easily formulated, if difficult to execute. Schmidt's requires the capture of ripe 'European' eels in the spawning area. Mine, the easier, would require experimental production of '*A. rostrata*'-type larvæ from artificially fertilized 'European' eel eggs; alternatively, from eggs collected at the northern limits of the original *A. anguilla* spawning area. The last experiment may have been performed already, quite inadvertently, unknowingly and successfully, by Fish[5].

On July 16, 1925, the *Arcturus* collected four eggs from 500 fathoms at 32° 02′ N., 65° 00′ W., which were reared in the laboratory by Fish and carefully and responsibly reported as *A. rostrata*; criticism of this identification[6,7] does not seem to be conclusively destructive. One larva was reared and had "between 105 and 110 muscle segments" when it died at 10 mm. An embryo had "at least 105 and not more than 109 segments", about 64 of them pre-anal and 41 post-anal. The temperatures of the water during incubation were recorded: 27·7° C. when cleavage began to 23·9° C. at hatching, a range of the order of 10° C. higher than that which would have been encountered in Nature. Thus, from north of the original *A. anguilla* ground were reared, under conditions in which a temperature effect must appear inevitable, larvæ which were arguably of '*A. rostrata*' type. That the eggs were so far north and late in the year and lacking a concentrated oil-globule, facts cited against the *Anguilla* identification, may be explained by the assumption that they merely represented one of many mistimed and misplaced spawnings and might well have died immediately but for their respite under laboratory conditions.

I would like to express my thanks to numerous colleagues, notably Dr. E. Trewavas and Mr. P. H. Greenwood, who have been my patient *advocati diaboli* during this work.

INFORMATION THEORY AND ITS APPLICATIONS TO FUNDAMENTAL PROBLEMS IN PHYSICS*

By Prof. L. BRILLOUIN

Columbia University, New York

THE scientific theory of information, developed during the past few years, has yielded some very important applications in the field of telecommunications, but it has also led to many interesting discussions about the fundamental definitions of experimental science. Among other things, it has obliged the physicist to re-examine the role of experimental errors and has required a complete re-appraisal of their actual importance.

Formerly, errors were usually considered as a secondary effect, a nuisance that could be neglected in most occasions, and which should be ignored by theory. The assumption was that errors could be made as small as might be desired by careful instrumentation, and played no essential part. This was the point of view of mathematicians discussing the axioms of geometry, and most physicists accepted, implicitly or explicitly, this kind of idealization. Modern physics has had to get rid of these unrealistic schemes, and to realize the unpleasant fact that errors cannot be made as small as one wishes, but must be taken into account as an integral part of the theory.

Errors, Uncertainties and Observations

Until the end of the nineteenth century, most scientists assumed that experimental observations could reveal the 'laws of Nature'; of course, observations were perturbed by all sorts of errors, but it was customary to generalize the imperfect data available and to formulate simple mathematical laws; these *exact* laws were supposed to govern the outside world, whether it could be observed in principle or not. For example, Newton's laws of mechanics and of universal gravitation were accepted as rigorous, even though they had been verified only within the limits of experimental error.

The first difficulties were encountered in connexion with statistical thermodynamics: How was it possible to derive irreversible thermodynamics from strictly reversible mechanical laws? There was also the problem of determinism, which was assumed to be proved by scientific investigations, although in practice it remained impossible to verify such a rule by any experimental device.

With Heisenberg's 'uncertainty principle', the importance of errors in observations came into the foreground. Physicists realized that it was impossible to measure accurately, and at the same time, a co-ordinate x and its momentum p_x, and that the corresponding errors were coupled by the relation:

$$\Delta x \,.\, \Delta p_x \geqslant h \qquad (1)$$

Any experiment measuring x with an error Δx perturbs the system and introduces an unknown change Δp_x in p_x, making its exact determination impossible. It is a fundamental and inescapable fact that an observation always creates a perturbation. If you have a physical system which is completely isolated and unperturbed, you cannot observe it. An observation necessarily requires a certain temporary coupling between the system and a measuring instrument; this coupling results in a perturbation of the observed system.

This general remark was given a precise statement in a law discovered by me, and called the 'negentropy principle of information'. It states that an observation yields a certain amount of information ΔI, that this information can be measured quantitatively, and compared with an inevitable increase in entropy ΔS in the measuring device during the experimental measurement. The net result is (in entropy units):

$$\Delta S \geqslant \Delta I \quad \text{or} \quad \Delta I + \Delta N \leqslant 0 \qquad (2)$$
$$\text{with } \Delta N = -\Delta S \quad \text{neg(ative) entropy}$$

These conditions mean that a finite amount of energy ΔE must be degraded and changed into heat:

---

* Based on a series of five lectures delivered at King's College, London, during October 21–29, 1958. Work done under contract *Nonr* 255 (56).

$$\Delta E = T\Delta S \geqslant T\Delta I \text{ (}T\text{, absolute temperature)} \quad (3)$$

The definition of the quantity ΔI can be summarized in a simple way[1]: let P_0 be the number of equally possible cases before the measurement, and P_1 the number of such cases after the observation. Then, by definition:

$$\Delta I = k \ln \frac{P_0}{P_1} \quad (4)$$

where k is Boltzmann's constant. If the accuracy is very high, P_1 becomes very small and the amount of information is very large. Infinite accuracy, with infinitely small error, would mean an infinite increase in information; hence an infinite amount of energy ΔE is degraded, which is quite impossible[2].

A similar opinion has been expressed by Born[4,5] in a series of papers based upon the obvious fact that every method of observation has its limitations, making experimental errors unavoidable. This is, in a general way, what is stated more precisely in our conditions 2.

When extreme accuracy is required, a new restriction arises, which makes it even more difficult to make a measurement of very small distances. It may be shown (ref. 1, p. 235) that a very large amount of energy ΔE is needed for the observation of a distance x within a very small error Δx:

$$\Delta E \,.\, \Delta x \geqslant \tfrac{1}{2}\, hc \quad (5)$$

This very large energy ΔE is partly dissipated, according to the previous conditions 2 and 3, and when Δx becomes extremely small (smaller than 10^{-13} cm., for example), the new condition 5 requires an expenditure in energy very much higher than that which would result from equation 3.

The preceding conditions 3 and 5 can be explained in simple terms. It has been realized since the work of Ising that Brownian motion (thermal noise) sets a limit to the accuracy of observations. Thermal agitation involves energies of the order of kT per degree of freedom. For a reliable observation of one degree of freedom, an energy larger than kT must be used in order to overcome irregular motions of magnitude kT. If the observation is made on many degrees of freedom, it will require an energy proportional to T; this energy is degraded, and yields an increase of entropy ΔS independent of T. This is practically the mechanism underlying equations 2 and 3.

As for condition 5, a simple numerical computation shows[3] that the energy ΔE, translated into electron-volts, corresponds to the many millions of volts required to measure the cross-sections of particles having very small diameters, Δx; relation 5, in fact, is applicable to the synchrotrons or other powerful accelerators used for measuring the very small cross-sections encountered in collisions of atomic particles.

To sum up: an observation is an irreversible process, necessarily involving an increase of entropy in the measuring apparatus: the information obtained is paid for in negentropy. As Gabor has commented, "You can never get something for nothing, not even an observation". This remark has far-reaching implications, which will now be discussed.

The Objective World and the Problem of Determinism

In a brilliant discussion, Schrödinger has explained[6] how much we owe to the Greek philosophers, from whom we inherited many fundamental ideas. These concepts have been extremely useful, but we have now reached a point where we must revise them drastically. The scientist used to step back into the role of an external observer, and to assume the existence of 'a real, objective world around us', governed by accurate mathematical laws (the laws of Nature), according to which it would proceed unperturbed, whether we observe it or not.

The modern point of view is different: when we are not making any observation, it must now be admitted candidly we do not know what is happening; and when we make an observation, we certainly perturb the 'outside world', by some coupling between observer and the observed. So the assumption of accurate laws of Nature is gratuitous; it is a philosophical creed, but it is not supported by experimental facts. All we can prove is the existence of certain correlations: given the result of a certain experiment, we are able to predict (within certain limits) the possible outcome of a later experiment. This, however, does not require any objective outside world: that is an additional assumption which may provide a convenient model for most large-scale experiments, but the model is definitely wrong at the atomic or sub-atomic scale.

Bridgman has repeatedly emphasized the danger of introducing into our theories too many unmeasurable quantities. Sooner or later these unobservable concepts will have to be rejected, and this will often mean a very painful re-appraisal of actual facts and data.

In many cases, strict causality must be replaced by statistical probabilities; a scientist may or may not believe in determinism. It is a matter of creed, and belongs to metaphysics; physical experiments are unable to prove or to disprove it. This general point of view may be called the 'matter-of-fact' point of view.

Relations 1 to 5 above show that it is quite impossible to eliminate experimental errors completely. They are not only a practical limitation but also they represent an absolutely unavoidable feature of the experimental method. Laplace invented, more than a century ago, a demon who was supposed to know exactly the positions and velocities of all atoms in the universe, and to compute exactly the future evolution of the whole world. The present discussion constitutes an exorcism of Laplace's demon. Both the uncertainty principle and the negentropy principle of information make Laplace's scheme of exact determinism completely unrealistic.

In order to measure very accurately the initial positions and velocities of all the atoms in the universe, the demon would need an infinite amount of energy, according to equations 3 and 5. The exact determination of initial conditions is thus physically impossible.

The negentropy principle of information had already provided a definite answer to the paradox of Maxwell's demon; it also eliminates Laplace's demon without further discussion. Experimental errors cannot be made as small as one may wish, for they belong to the actual facts of experiment and must be included in the theory.

PHOTOREACTIVATION OF NUCLEIC ACID FROM TOBACCO MOSAIC VIRUS

By F. C. BAWDEN, F.R.S., and A. KLECZKOWSKI
Rothamsted Experimental Station, Harpenden, Herts

SOME types of injury caused by ultra-violet radiation to systems containing nucleic acids can be reversed by subsequent exposure to visible light. Irradiated viruses cannot be directly photoreactivated; but, except for strains of tobacco mosaic virus, all those yet reported on can be reactivated by exposing recently infected hosts to visible light[1]. In other words, when irradiation has destroyed about 99 per cent of the initial infectivity of a preparation, only strains of tobacco mosaic virus have shown the same residual infectivity whether inoculated hosts are kept in light or in darkness. Two explanations for their exceptional behaviour are self-evident: (1) their nucleic acids may be exceptional in not undergoing the type of change that is reversed by visible light; or (2) the manner in which their nucleic acids is combined with protein may prevent them from undergoing the reversible changes. *A priori*, as the morphology of tobacco mosaic virus differs from that of photoreactivable viruses, the second explanation seemed more likely to be true. Also, there is evidence that the protein protects against ultra-violet radiation, for the nucleic acid needs much more irradiation to be inactivated to a given level when in the virus than when free[2]. That the manner of combination with protein, or the quality of the protein, also affects sensitivity to irradiation is shown by the fact that different strains of the virus inactivate at different rates when intact, although their separated nucleic acids are equally sensitive[3].

The discovery that preparations of the nucleic acid from tobacco mosaic virus can be infective[4,5] made it possible to test these alternative explanations. This we have done and found that nucleic acid irradiated when freed from its protein can be photoreactivated. This alone would not establish the fact that the protein protects against the reversible type of irradiation damage, for the protein might prevent visible light from reversing the damage. However, the point seems to be fully established by the fact, shown in Table 1, that nucleic acid separated from irradiated virus was not photoreactivated. The solution of tobacco mosaic virus was irradiated so that about 99 per cent of the initial infectivity was destroyed, and the residual was the same whether measured on plants kept in light or darkness. The nucleic acid was separated from the virus by the phenol method[5] and its infectivity compared with that of nucleic acid similarly separated from unirradiated virus. The relative infectivities of the two nucleic acid preparations were of the same order as those of their parent virus preparations, and were the same whether the test plants were kept in light or darkness after inoculation.

Table 1. FAILURE OF LIGHT TO AFFECT INFECTIVITY OF NUCLEIC ACID FROM IRRADIATED TOBACCO MOSAIC VIRUS (T.M.V.)

Inoculum	Dilution of the inoculum	Total number of local lesions obtained on twelve half-leaves	
		Dark	Light
Irradiated 1 per cent T.M.V.	1/50	401	416
Non-irradiated 1 per cent T.M.V.	1/2,000	783	860
	1/10,000	397	417
	1/50,000	132	139
Nucleic acid from irradiated 1 per cent T.M.V.	1/1	45	42
	1/5	10	7
Nucleic acid from non-irradiated 1 per cent T.M.V.	1/20	198	172
	1/100	38	23
	1/500	9	7

5 ml. of a 1 per cent solution of tobacco mosaic virus in *M*/60 *p*H 7·0 phosphate buffer were irradiated at 3,030 μW./cm.^{2} in a Petri dish of dia. 6·6 cm., so that 2·5 joules were absorbed and scattered per 1 mgm. The number of lesions obtained with the intact virus cannot be directly compared with those obtained with the nucleic acid, for they came from different tests on different sets of *Nicotiana glutinosa* plants. 'Dark' and 'Light' mean respectively that the plants were in darkness or daylight after they were inoculated.

Table 2. PHOTOREACTIVATION OF NUCLEIC ACID IRRADIATED WITH ULTRA-VIOLET LIGHT AFTER ISOLATION FROM THE VIRUS

Time of irradiation (min.)	Absorbed energy (joules per mgm.)	Dilution of inoculum	Number of lesions		Log$_{10}$ of remaining proportion of initial infectivity			
			Dark	Light	Found Dark	Found Light	Computed Dark	Computed Light
1·25	0·63	1/1	297	722	−1·1	−0·53	−1·0	−0·5
3·5	1·76	1/1	11	194	−2·7	−1·4	−2·8	−1·4
0	0	1/5	596	543	—	—	—	—
0	0	1/50	91	100	—	—	—	—
0	0	1/500	12	7	—	—	—	—

The undiluted nucleic acid was a 0·66 mgm./ml. solution in *M*/60 *p*H 7·0 phosphate buffer, of which 2·5 ml. were exposed to radiation of intensity 870 μW./cm.^{2} in a Petri dish of dia. 4·5 cm. The log. of the remaining proportions of the initial infectivity were found from the curve obtained by plotting the numbers of lesions produced by the control preparation against the log. of their dilutions. The computed values were obtained from the equation $\log_{10} p = -kv$, where p is the remaining proportion of the initial infectivity, v is the energy absorbed in joules per mgm. and k is assumed to be 0·79 with photoreactivation ('Light') and 1·58 without photoreactivation ('Dark').

Nucleic acid preparations have only a small fraction of the infectivity per unit of phosphorus of intact virus and most of this must be destroyed to demonstrate photoreactivation. Hence, the test plants (*Nicotiana glutinosa* L.) must be highly susceptible, and ours were raised in shade and kept at 37° for a day before they were inoculated. Both these treatments increase susceptibility to infection by intact virus but do so much more when nucleic acid is the inoculum. Table 2 shows the results of an experiment in which two aliquots of nucleic acid made by the phenol method from a 2 per cent virus solution were irradiated to different extents, after which their infectivity was compared with that of unirradiated nucleic acid inoculated at three concentrations. The nucleic acid was kept at 0° between the time it was made and used as inocula, and samples were irradiated as thin layers in Petri dishes kept rocking in a bath of iced water. Twelve plants were used, and each solution was inoculated to twelve half-leaves distributed equally on each plant and at each leaf position. After inoculation, six plants were exposed to daylight and six put in darkness. The greater relative infectivity of the irradiated nucleic acid in plants in the light is obvious. With or without photoreactivation, inactivation approximately follows first-order kinetics, with photoreactivation equivalent to halving the dose of radiation. This factor of two places the nucleic acid of tobacco mosaic virus second only to potato virus *X* when plant viruses are listed according to the extent they show photoreactivation[1], but as the other viruses were irradiated only when intact, their nucleic acids might show the phenomenon more strongly if irradiated free from their protein.

McLaren and Takahashi[2] found that the infectivity of nucleic acid preparations was halved when 1 mgm. absorbed 0·43 joule. They do not say how their inoculated plants were treated, but it is likely they were placed in the light, for this value is close to the 0·38 joule which can be calculated from the data in Table 2 for plants in the light, whereas the value for 50 per cent inactivation without photoreactivation is 0·19.

Siegel, Wildman and Ginoza[3] concluded that the differences between sensitivity of different strains of tobacco mosaic virus reside in the nature of the bonding between the protein and nucleic acid. As none of the strains yet tested, although they differ in their sensitivity to inactivation, shows photoreactivation when irradiated intact, all seem to share a type of bonding that protects the nucleic acid from changes reversed by light. We have not attempted to see whether recombining separated nucleic acid with the protein would prevent photoreactivation, but the type of bonding in 'reconstituted' virus particles seems to differ from that in the original virus because the recombination does not restore the original degree of resistance to inactivation by irradiation[3]. Even the most sensitive strain of tobacco mosaic virus requires much more energy to be inactivated than does potato virus *X*, which has the same content of nucleic acid. It seems, then, that the nucleic acids of different viruses may resemble one another in sensitivity to irradiation and in undergoing more than one type of change, but that their proteins protect them to very different extents from changes of different kinds. It is possible that we have not measured the full potential of tobacco mosaic virus to be photoreactivated, for separating the nucleic acid from its protein may have changed some of the groups that otherwise could have undergone reversible changes.

We used two low-pressure mercury lamps, both of which have most of their radiation of wave-length 254 mμ, and one of which had a filter excluding wave-lengths shorter than 240 mμ. Both gave qualitatively similar results: photoreactivation when the separated nucleic acid was irradiated, but not when intact virus was, whether the inoculum was intact virus or nucleic acid separated from the irradiated virus.

OBITUARIES

Sir Claude Gibb, K.B.E., F.R.S.

SIR CLAUDE DIXON GIBB, who died suddenly in the United States on January 15, was one of the outstanding engineers of our time. He was also pre-eminent as an administrator, manufacturer and scientist. He was sixty years of age.

After qualifying at the University of Adelaide, he became a senior research assistant in the Engineering Laboratory there after a short interruption as a pilot in the Royal Australian Flying Corps. He went to Great Britain in 1924 to gain experience as a fitter with the firm of Messrs. C. A. Parsons and Co., Ltd. Such was his ability that he was made general manager in 1937 and managing director in 1943. In 1940, loaned by his Company to the Ministry of Supply, he rapidly moved from engineering assistant to director-general, Munitions Production, and afterwards to director-general, Armoured Fighting Vehicles, and chairman of the Tank Board.

He was elected a Fellow of the Royal Society in 1946 and has been noted for his particular interest in research, originally on steam turbine components and latterly in nuclear work for the production of power. In 1946 he was appointed a member of the Board of the National Physical Laboratory, and became a member of the Council of King's College, Newcastle upon Tyne, in the same year.

In 1947 Sir Claude was appointed a member of the Advisory Council on Scientific Policy and became chairman of the Committee on Research and Productivity. He has also been chairman of the Sectional Committee on Engineering of the Royal Society and was a member of the Mechanical Engineering Research Board of the Department of Scientific and Industrial Research. In 1949 he was a vice-president of the British Association and in 1951 president of Section *G* (Engineering) of the Association. He was also chairman of the Board of Governors of the Rutherford College of Technology.

Sir Charles's own scientific work has been described in technical papers given to the major institutions in Canada, Australia and the United Kingdom. Under him, Messrs. C. A. Parsons have an order for a 550 MW. set for the Thorpe Marsh Power Station—at this time the largest in the world. As a result of his work, this Company became the main contractors for the first nuclear power station, namely, Calder Hall. The Company has also been engaged in the very large items of equipment for Chapelcross Power Station and the large new power station under construction at Bradwell. Sir Claude was also mainly instrumental in the negotiations in Italy to build a nuclear power station at Latina, near Rome.

Sir Claude received many well-deserved honours. Such is the brilliant record of a man who from fundamental knowledge of science with a strong basis of practical imagination brought so much honour to the firm and country which he chose as his own.

T. W. F. BROWN

Prof. W. Wardlaw, C.B.E.

The very large number of scientists who knew him personally were grieved to learn of the death of Prof. William Wardlaw on December 19, at the age of sixty-six.

Wardlaw was educated at Newcastle upon Tyne, first at Rutherford College, and then at Armstrong College, in the University of Durham. Although he lived for a large part of his life in the Midlands and in London, he never forgot his connexion with Northumberland and often referred with pride to his early days in the North Country. In 1918 he joined the staff of the Department of Chemistry, University of Birmingham. He proved to be an admirable university teacher and progressed to the rank of senior lecturer in inorganic chemistry. He was appointed to the chair of physical chemistry in the University of London, tenable at Birkbeck College, in 1937, and he held his professorship for twenty years until his retirement in 1957, when the title of professor emeritus was conferred on him.

For more than forty years Wardlaw carried out valuable research in inorganic chemistry. During the early stages of his career he investigated some inorganic oxidation processes and made contributions to the chemistry of molybdenum. In the 1930's his interest turned to the stereochemistry of metal complexes. This subject continued to hold his attention for the rest of his life, and by his work he made an important contribution in this field of study. On taking up his appointment in London, Wardlaw had barely succeeded in getting his new department organized when the Second World War began and a halt was called to his research activities. At the conclusion of hostilities he was faced with two major tasks. He had to build up afresh a research group, and to plan and equip a new department, since his College was transferred to new quarters in Bloomsbury. He attacked both tasks with characteristic vigour. An extensive programme of research on the esters of transition metals was initiated, and under his direction a flourishing research school was developed in the new well-equipped laboratories. The results of this last phase of his research work have had an important influence on the development of modern ideas of the inter-relation of physical properties with molecular structure.

Wardlaw held strongly the belief that university scientists should not lead an 'ivory tower' existence, and he seized every opportunity to broaden the impact of chemistry upon the community. He sought to widen the range of contacts of scientists in the universities, in industry, and in research associations, and his membership of the Society of Chemical Industry dated from 1917. He was extremely sympathetic towards the difficulties which faced science masters in schools through poor laboratory accommodation, and often spoke up strongly on this point. Scientific publication interested him enormously, and he gave considerable thought to the best ways of dealing with the ever-increasing volume of chemical papers. To the professional societies he gave generously of his time and found much pleasure in this service. In later life he reached high office in these societies, but his many friends testify that his support was equally enthusiastic at the commencement of his career.

During the difficult period 1940–48, he was honorary secretary of the Chemical Society, and he became president for 1954–56. His first membership of the Council of the Royal Institute of Chemistry dates from 1929 and at the time of his death he was president. To be elected president of both the Chemical Society and the Royal Institute of Chemistry is an honour accorded to few, and is a measure of the esteem in which Wardlaw was held by his professional colleagues and the confidence which his sound judgment inspired.

He had strong sympathy with the aims of the British Association, and the active part he played in its affairs demonstrates his strong conviction that the chemist has responsibilities which extend beyond the boundaries of his profession. In 1952 he presided over the meetings of Section *B* (Chemistry) and more recently took office as one of the general secretaries. He was closely connected with the current developments in the activities of the Association.

During the Second World War Wardlaw was a joint secretary of the War Cabinet Scientific Advisory Committee, after which he became scientific advisor to the Committee of Appointments in the Ministry of Labour and National Service. Undoubtedly he had a flair for accurate judgment of character and ability, and his advice has been of great national benefit. In 1949 he was created C.B.E.

Wardlaw was always sympathetic to his students and ready to assist in their problems : they responded to his interest with a deep sense of respect and grateful affection. He could not bear slipshod work or laziness, and on occasion his comment and censure could be forthright.

Being a humorous man of much charm, he had a great many friends. His colleagues at Birkbeck College and throughout the University of London always welcomed his company and found joy in his unvarying friendliness. His devoted and wholely selfless service to learning, the public welfare, the advancement of science and the selection and production of scientists, add up to a life-time's work of inestimable value. Scientists, and especially chemists, owe a great deal to Wardlaw, and it is hard to realize that no longer will it be possible to call on his services or to seek his wise counsel.

In 1932 he married Doris Whitfield, who had herself been trained as a chemist, and he never failed to pay tribute to her sympathetic understanding and help in his work. She and their daughter survive him.

W. G. Overend

Prof. A. R. Fulton, M.B.E.

Angus Robertson Fulton, emeritus professor of engineering and drawing in the University of St. Andrews, died at his home in Dundee on November 21.

Born in Dundee on June 23, 1871, he suffered the early misfortune of being left an orphan at the age of five. This affected his opportunities for education, but by courage and determination he acquired a training as an engineer. On qualifying, he worked for some years with Hurst and Nelson, of Motherwell, and it is a testimony to his ability that, although up to that stage he had no university degree, he was invited by Prof. T. Claxton-Fidler to be his assistant in the Engineering Department of University College, Dundee. He spent the rest of his professional life, from 1902 until 1946, on the staff of that Department.

He graduated B.Sc. in 1907, and was the main assistant, first, to Prof. Claxton-Fidler, then to his successor, Prof. A. H. Gibson. During the First World War he served for some time in the Royal

Flying Corps and worked as an investigator of accidents caused by mechanical failures. For this work he was mentioned in dispatches and was made M.B.E.

On returning to Dundee, he continued his researches on stresses in materials and received the degree of D.Sc. in due course. He was appointed professor of engineering and drawing in University College, Dundee, in 1920, and held this post until he retired in 1946. During 1939–46 he was also principal of University College, Dundee. In both posts he was highly respected by his colleagues for his academic abilities, for his powers as an administrator, and for his sincerity.

J. DICK

NEWS and VIEWS

Zoology at Cambridge:

Sir James Gray, C.B.E., F.R.S.

SIR JAMES GRAY, who is to retire from the chair of zoology at Cambridge in September, has been one of the chief architects of the structure of modern British zoology. He and the men and women he has trained have been largely responsible for the growth of experimental zoology and for the replacement of comparative anatomy by studies of the living animal in zoological laboratories throughout the Commonwealth. After serving with distinction in the First World War, he returned to Cambridge as Balfour student and then as reader in experimental zoology; his cytological researches during this period culminated in the publication of "Ciliary Movement" in 1928 and "A Textbook of Experimental Cytology" in 1931. The design and building of the new zoology laboratory at Cambridge during 1932–34 provided him with his first major administrative task and it is a tribute to his skill that few people who work there to-day would wish to change the building. He was appointed to the chair in 1937 at a time when his interests were moving away from cytology to the analysis of animal movement, and he pioneered the application of physical principles to many different aspects of this study. Until after the Second World War his work was perhaps not widely known to the world at large, but this was remedied in 1951 by a series of Christmas Lectures at the Royal Institution, which were afterwards published under the title "How Animals Move". Before, and even more after, the War he has been active in the wider spheres of administration, being president of the Marine Biological Association, twice on the Council of the Royal Society, a member of the Agricultural Research Council during 1942–47 and for many years a development commissioner and chairman of the Advisory Committee on Fishery Research. This year he is president of the British Association. As editor, almost from its inception until 1954, of the *Journal of Experimental Biology* he has made a notable contribution to clarity in the publication of scientific results. Altogether, his influence will continue to be felt in his subject for many years.

Prof. C. F. A. Pantin, F.R.S.

DR. C. F. A. PANTIN, who has been elected to succeed Sir James Gray as professor of zoology in the University of Cambridge, has been reader in invertebrate zoology in the University since 1937. After taking his degree from Christ's College, Cambridge, he was physiologist to the Marine Biological Laboratory, Plymouth, during 1922–29, and returned to Cambridge as Harding Lecturer and Fellow of Trinity College in 1929. His researches have ranged over a wide field of invertebrate zoology. During 1923–31 he published a series of papers which laid the foundation of our knowledge of amœboid movement; in 1931 he established the role of calcium in the osmotic regulation of the body fluid of the marine worm *Gunda* (*Procerodes*). His analysiis during 1934–36, of the physiology of crustacean muscle was the starting-point for extensive subsequent work on this tissue; at this time also he became interested in the Coelenterata, the neuromuscular physiology of which he has continued to clarify in a series of papers since that date. On his appointment to the readership, he found time to study the terrestrial Nemertines, hitherto largely unknown in Britain. His experiments have been characterized by a clarity and simplicity which has made them the basis of practical courses in comparative physiology throughout the world; his insistence on the need for a parallel study of structure and function has done much to unify the different approaches to the study of invertebrate animals.

Dr. Pantin was president of Section *D* of the British Association in 1951, Croonian lecturer of the Royal Society in 1952 and is now president of the Linnean Society. He has given much assistance and encouragement to marine biology overseas, particularly in New Zealand and Brazil. Since 1947 he has been editor of the *Quarterly Journal of Microscopical Science*. His wide experience and skill as a teacher will ensure the continuation of the high standards of zoology at Cambridge.

California Institute of Technology, Radio Observatory:

Dr. J. G. Bolton

JOHN GATENBY BOLTON has been appointed the first director of the California Institute of Technology's newly established Radio Observatory, which is situated near Big Pine in the picturesque Owens Valley of California. Bolton, while a member of the Radiophysics Division of the Australian Commonwealth Scientific and Industrial Research Organization, was responsible for some of the pioneering discoveries in radio astronomy, notably of the existence of 'radio stars'. In 1947, he was the first to put an upper limit (8′ of arc) on the size of the previously reported source in Cygnus, to define its position with sufficient accuracy to be able to say it was in a region of the Galaxy distinguished by the absence of bright stars and nebulæ, and to point out that the radio noise from it was out of all proportion to the optical radiation. Soon after, in 1948, he announced the position of other point sources; made the first identification with an optical object—that in Taurus with the Crab Nebula, the remains of an old supernova; and took some of the first steps in using the radio observations to throw new light on the structure of the Galaxy. With this background, it is not surprising that the research programme of the new Radio Observatory will be concerned principally with studies of radio stars. The main instrument will be an interferometer consisting of two steerable parabolic reflectors, each 90 ft. in diameter and having a mesh covering suitable for use down to 3 cm. The reflectors are each mounted on bogies on 35-ft. gauge railway tracks running north–south and east–west, so that when the pair is used as an interferometer the spacing and orientation can be varied.

The Institution of Electrical Engineers : Mr. C. W. Speirs

MR. CHARLES W. SPEIRS has been elected to honorary membership of the Institution in recognition of his contributions to the advancement of electrical science and engineering, and of his outstanding support for the work of the Institution, particularly of its Incorporated Benevolent Fund. Mr. Speirs studied at the University of Durham and in 1891 entered the works of Messrs. C. A. Parsons and Co. at Heaton as an engineering apprentice. In 1898 he joined the Morgan Crucible Co., Ltd., as engineer and technical adviser, remaining with that organization until his retirement in 1933. In 1944 Mr. Speirs made a substantial gift of land from his estate at Malden, accompanied by a notable endowment, to the Incorporated Benevolent Fund. These gifts, supplemented by the contributions of members to the 'Homes Fund', brought into being the residential estate for beneficiaries of the Fund known as the Chesters Estate.

Signor Luigi Emanueli : Faraday Medallist

SIGNOR LUIGI EMANUELI (who, we regret to announce, died on February 17) has been awarded the thirty-seventh Faraday Medal of the Institution of Electrical Engineers for his outstanding contribution of inventions and new applications in the field of electrical cables, and particularly for the invention of the oil-filled cable. Signor Emanueli, who was born in Milan in 1883, graduated in electrical engineering from the Milan Polytechnic in 1906. He is vice-president of the Pirelli Company of Milan, where he started his professional life in 1907. He was elected a member of the Institution of Electrical Engineers in 1922. Signor Emanueli has been connected with numerous scientific inventions and applications in the electrical cable and the rubber industries including the oil-filled cable, universally known as the Emanueli cable, which represents a turning point in technical progress in this field.

Increased Grants for Universities in Britain

IN a written answer in the House of Commons on February 9, the Chancellor of the Exchequer, Mr. D. H. Amory, said that the University Grants Committee has recommended that in consequence of unexpected increases in student members and also increases in costs, the recurrent grants to universities in Britain for the last three years of the quinquennium should be increased. Existing grants were fixed on the expectation that by 1961–62 the number of full-time students would rise to about 102,000. In the current academic year this estimate would be exceeded by at least 6,500 and by the end of the quinquennium the increase was likely to be even greater. Mr. Amory said he is satisfied that some further assistance should be given to the universities and stated that he proposed to ask Parliament to provide for an increase of £2,550,000 in the recurrent grants for 1959–60, £2,660,000 for 1960–61 and £2,720,000 for 1961–62, exclusive of the provision required to meet the improved salary scales announced on March 12, 1957.

Research on Fuel and Power in Britain

THE Parliamentary Secretary to the Ministry of Power, Sir Ian Horobin, replied in the House of Commons on Monday, February 9, to a series of questions about fuel and power research. He said that the Scientific Advisory Council of the Ministry of Power is concerned with the co-ordination and development of research in the utilization of the fuel resources of Britain. The Council works under an independent chairman and includes representatives of the fuel and power industries, the Department of Scientific and Industrial Research, industry generally and the universities. Experimental work with liquid methane is being paid for by the British gas industry and the American interests concerned, and the total cost to the gas industry is estimated at £1·5 million. The National Coal Board has decided to terminate experimental work on underground gasification at Newman Spinney on the ground that present results do not justify further expenditure. Research on the production of gas from oil is being concentrated upon hydrogenation of oil, and a commercial plant to work initially on oil and later on coal has been commissioned by the Gas Council. The gas industry estimates that its consumption of tail gas and other refinery surpluses may increase, in terms of coal equivalent, from the present 500,000 tons to 2 million tons in 1965.

The Tropical Products Institute

THE Tropical Products Institute is to become one of the research stations of the Department of Scientific and Industrial Research, following the decision to transfer the responsibility for the Institute from the Secretary of State for the Colonies to the Lord President of the Council, so that Commonwealth countries which have recently achieved independence, and thus no longer come within the scope of the Colonial Office, may still avail themselves of the services of the Institute. Support will continue to be provided by the Colonial Office, from the Colonial Development and Welfare Funds, for work of primary interest to the Colonies. The main objective of the Tropical Products Institute is to ensure the economic viability of the under-developed territories of the Commonwealth within the tropics, by improving the technology of industries that already exist and introducing new industries as a result of research into new uses for tropical plant and animal products (including waste products of existing industries). Particular attention will be directed to the needs for diversification in those territories which have a one-crop economy.

New European Nuclear Energy Project

THE third international project in the programme of the European Nuclear Energy Agency for the development of nuclear power for peaceful purposes on a European basis has been approved by the Agency's Steering Committee. Six European countries, together with Euratom, will combine in a joint investigation of the use of high-temperature gas-cooled reactors for nuclear power stations and other applications. The new project, known as *Dragon*, will be based mainly on the construction of an experimental power-producing reactor, developing several megawatts, at the United Kingdom Atomic Energy Authority's Research Establishment at Winfrith Heath in Dorset. The cost of the five-year programme of research and experiment is estimated at some £13·6 million. £10 million will be provided by the United Kingdom, Euratom (43·40 per cent each), Austria, Denmark, Norway, Sweden and Switzerland. The excess £3·6 million will be borne by the United Kingdom, which will retain ownership of the reactor and installations on conclusion of the *Dragon* project. The agreement inaugurating the project is expected to be signed at the Organization for European Economic Co-operation headquarters in Paris. Previous joint nuclear energy undertakings initiated by the European Nuclear Energy Agency comprise a twelve-country Convention setting up the European Company for the Chemical Processing of Irradiated Fuels (Eurochemie) with plant and laboratories under construction at Mol in Belgium; and a Boiling Heavy Water Reactor at Halden in Norway, in the operation of which five Organization member countries and the Euratom Commission are participating.

New Reactor to be Built at Windscale

A NEW low-power research reactor is to be built at Windscale, which is being expanded as one of the national centres for the development of gas-cooled reactors. The new reactor, to be known as *Hero* (hot experimental reactor of zero power), will cost about £1¼ million and will be built near the advanced gas-cooled reactor (*Agr*), on which work has already started. Its function will be to complement the work of *Agr* by making it possible to carry out measurements at low radiation-levels and to experiment with several alternative arrangements of fuel to obtain the best results. It will be completed early in 1961 and will be operated and studied by physicists of the Research and Development Branch of the United Kingdom Atomic Energy Authority at the Windscale laboratories. *Hero*, which will generate a few kilowatts of heat, will consist initially of a graphite structure 19 ft. in diameter and 19 ft. high, but an important feature is that it will be possible to dismantle it and rebuild it in a variety of ways. The graphite core will be contained in a steel vessel connected to a pipe circuit with pumps and heaters so that it can be operated at high temperature in carbon dioxide. It will, in fact, be the reverse of *Agr*, since the carbon dioxide gas will supply heat to the core instead of removing heat from it. The fuel will consist (as in *Agr*) of clusters of rods of uranium oxide sealed into beryllium cans, arranged in channels in the graphite in a regular lattice.

Advanced Gas-cooled Reactor Power Stations

IT is expected that from about 1965 onwards the reactors for nuclear power stations in Britain will be based on *Agr*, using uranium oxide fuel and beryllium instead of magnesium cans. This will permit higher operating temperatures and heat ratings and consequently will lead to greater efficiencies than can be achieved in the reactors now being built for the electricity authorities. The levels of radiation inside the reactors will be considerably higher. Two broad categories of problems are raised by these more severe conditions: those of reactor physics and those of reactor materials. The most important material problem is to develop fuel elements which can withstand high burn-up under the exacting conditions of high temperature and high flux, and the main purpose of the *Agr* prototype is to test various types of fuel at high power for prolonged periods (100,000 kW. of heat). It is essentially a fuel-element development reactor. The reactor-physics problems concern the behaviour of neutrons within the reactor. The high radiation-levels necessary in *Agr* for fuel testing and power production prevent the physicist from gaining access to the parts of the reactor which need most careful study. Sensitive techniques, however, are available with which it will be possible to carry out the necessary measurements at low radiation-levels in *Hero*. In addition, there are the problems of the kinetics and stability of highly rated reactors. *Agr* fuel is intended to remain in the reactor for a long time, building up very substantial amounts of plutonium. The reactivity of such a system is strongly dependent both on the fuel and moderator temperatures and on the isotopic content of the fuel, and careful study is therefore needed of the stability and control of such reactors.

Conservation Corps for Young Volunteers

ONE important purpose of the Council for Nature is to assist in the conservation of areas important to naturalists and country-lovers. The Council for Nature has embarked on a new venture and has started to organize a Conservation Corps for young volunteers. The volunteers will combine a holiday of manual work on a site needing attention with study of the natural history of the area under expert guidance. This scheme will achieve two ends: the education of young people in the principles of nature conservation, thus establishing a pool of future leaders for further studies in natural history; and the restoration and preservation of areas of special interest for future generations. This plan will require expenditure over the next five years of £25,000, and towards this the Carnegie United Kingdom Trust is making a provisional grant of £9,000 to be spread over the first three years. The response from other sources, particularly the larger industrial firms, has been encouraging and the Council is confident that the project will develop in its entirety. The Council has appointed as organizer of the Conservation Corps Brig. E. F. E. Armstrong, a retired officer of the Royal Engineers. His last Army appointment was concerned with the selection of young men and women for regular commissions, and since leaving the Army he has been warden at the Loughborough College of Technology. He has had considerable experience in the Boy Scout movement and Toc H and is also a keen naturalist.

Regiomontanus's Astrolabe at the National Maritime Museum

THE National Maritime Museum has recently placed on exhibition a small brass astrolabe made in 1462 by Johannes Muller, of Königsberg, known to posterity by his Latin name, Regiomontanus. This astrolabe was the first scientific instrument he made—it was a gift to his patron, Cardinal Bessarion, who had brought the young scholar to Rome from Nuremberg and given him access to his fine manuscripts on classical Greek astronomy. Later, Regiomontanus returned to Nuremberg and erected there an observatory, a press for printing scientific books and a workshop for making scientific instruments. It is this activity, spreading out from his centre, that marked the rebirth of astronomy and the beginning of the Renaissance of science. The astrolabe is a circular star map that can be rotated so as to calculate the positions of the Sun and the stars at any time of any day of the year; it could also be used for simple observations. The style of the instrument and its special arrangement of star pointers were copied by later workers, and the exquisite craftsmanship pointed clearly the way of later precision instruments. The instrument was presented to Dr. William Somerville (husband of Mary Somerville, after whom Somerville Hall, Oxford, was named) in Rome; he gave it to his friend, Sir John Herschel. It has remained in the Herschel family ever since and has now been lent to the Museum by Commander M. H. Hardcastle, R.N.

Council of Europe Competition in Advanced European Research

A prize of one million French francs is to be awarded every two years by the Secretariat-General of the Council of Europe for an original thesis of high academic standard on a given subject of European importance. It must not have been previously published, and must represent an original contribution on the subject set. The subject chosen for the first competition is "Consequences of the Use of Nuclear Energy for the European Mode of Life". Theses may be written in English, Dutch, French, German, Italian or Spanish, and entries must be submitted before the end of 1960. A jury, chosen by the Secretariat-General on the advice of the Committee of Cultural Experts of the Council of Europe, will award the prize. Further information can be obtained from the Secretariat-General, Council of Europe, Strasbourg, France.

Support for Institutes for Advanced Study in Science

The North Atlantic Treaty Organization has established a fund to provide financial assistance to institutes and summer schools for advanced scientific study in those cases where a large degree of international participation is anticipated among both the faculty and the students. No precise pattern has been defined for eligible institutes, but it is expected that the programmes will normally last between two weeks and two months, will be at a postgraduate or higher level, and will provide for concentrated study of a restricted scientific field. It is hoped that this fund will encourage the establishment of institutes for advanced study similar to the highly successful summer schools of theoretical physics at Les Houches and Varenna, but in other scientific fields. Institutes and summer schools for advanced study in any of the natural sciences or technology may appropriately apply for grants. Although the eligible institutes must be situated in one of the fifteen member nations of the North Atlantic Treaty Organization, no nationality or other restrictions for either the staff or the students are in any way implied. Further information on the programme can be obtained from the Science Adviser, NATO Headquarters, Palais de Chaillot, Paris XVI, to whom applications for grants should be made.

Reform of the Calendar

A brief review of the history of the calendar by Y. G. Perel (*Priroda*, 7, 47; 1958) suggests the urgent desirability of establishing a world calendar, such as was proposed by India in 1953 before the United Nations. According to this proposal, the year will be divided into four quarters of thirteen weeks each, with the first month of thirty-one days and the following two of thirty days each. An additional day (the day of peace and friendship) is added after December 30, and on leap years an additional day after June 30.

The Rockefeller Institute Press

The Rockefeller Institute Press has been established to publish books on science and related subjects in association with the Oxford University Press, New York. Editorial responsibility for the books will rest primarily with the Institute, while Oxford will be chiefly responsible for design, printing and distribution. It is expected that the first books will be issued in the autumn of 1959. While many of the books and monographs will be the work of Institute faculty members, works by others will also be published. The Rockefeller Institute Press will be under the direction of Charles I. Campbell, administrative associate for information services at the Institute.

Lapis

Lapis, a monthly journal of industrial opportunities, the first number of which appeared in October 1958 (pp. 28. Subscription rates, including postage for one year: inland, £10 10*s*. 0*d*.; abroad, U.S.A. and Canada, 30 dollars; France, 15,000 francs; Italy, 19,000 lire. London: Kenneth Mason, 1 Old Burlington Street, W.1), lists patents available for disposal by licence or sale. These are classified in two parts: general, mechanical and electrical; and chemistry and chemical engineering. There is also a list of agents and agencies wanted. Details of patents for disposal and partnerships for development are sought from all over the world.

National Museum of Wales

The annual report of the National Museum of Wales for 1957–58, after giving details of the personnel of Court, Council and staff, records that the third application to the Treasury for permission to establish a Department of Industry was granted. A sum of £2,000 was provided for this purpose. To supplement this an appeal for £5,000 has been addressed to local industrialists. The keeper of geology, Dr. F. J. North, acted as keeper of the new Department, and in addition to arranging a typical exhibit illustrating the development of the miners' safety lamp, was able to establish some useful contacts for the future. An impressive series of seventeen temporary exhibitions was arranged during the year. In the Department of Geology the emphasis has been on the reserve and study collections, while the chief task of the Department of Botany was to organize an exhibition illustrating paper and its uses. In the Glanely Gallery three cases, "Animals without Backbones", "Butterflies and Moths" and "The Main Group of Insects", were entirely re-arranged, while in the Department of Archæology reorganization has continued. In the Department of Art displays of Sheffield plate, the regalia of the Gorsedd of Wales have been added and other exhibits enlarged. The Welsh Folk Museum was chiefly concerned during the year with the re-erection of three houses from Cilewent, Radnorshire; Hendre'r-Wydd, Denbighshire; and Llandfadyn, Caernarvonshire. Such a record of progress in all Departments is a measure of the devotion of the staff of this Museum to the interests of the community.

1959 Waverley Gold Medal Competition

The Waverley Gold Medal and a prize of £100 will be awarded for an essay of about 3,000 words based on recent scientific research or development (whether the author's work or not), giving an outline of the scientific background, the experimental results and its potential application in industry. Essays will be judged for technical content, clarity of presentation and for style. A second prize of £50 will also be awarded; and an additional prize of £50 is offered for the best entry from a competitor under the age of thirty on July 31, 1959. The competition is open only to persons engaged in scientific work during January 1–July 31, 1959. Further details can be obtained from the Editor, *Research*, 4/5 Bell Yard, London, W.C.2, to whom all entries must be submitted before July 31.

Bell Telephone Laboratories: Kelly Award

Bell Telephone Laboratories and the American Institute of Electrical Engineers have announced the establishment of an award for achievement in the field of telecommunications, to be known as the Mervin J. Kelly Award. The award is named in honour of Dr. Kelly, formerly president and now chairman of the board of Bell Laboratories, who will retire on March 1 after forty-one years of scientific and administrative service with the Bell Telephone System (*Nature*, 183, 221; 1959). The Kelly Award will be given annually by the American Institute of Electrical Engineers to an individual who has made an outstanding contribution to the advancement of telecommunications. The prize will consist of a bronze medal, a cash award of 1,000 dollars and a certificate. The first award will be made in 1960. The Award is being sponsored by Bell Laboratories but will be administered solely by the Institute.

"Electrode Potentials and Compound Formation in the Palladium–Platinum–Hydrogen System"

Referring to the communication under this title in *Nature* of January 3, p. 39, Messrs. A. W. Carson, T. B. Flanagan and F. A. Lewis write: "The platinum content of the palladium–platinum alloys investigated should be read as weight per cent. It had previously been reported (Stetsenko, A. I., and Tverdovskii, I. P., *Zhur Fiz. Khim.*, 26, 647; 1952) that the upper limit of platinum content in palladium–platinum alloys, which allows of the formation of a two-phase region close to 25° C. in the palladium–platinum–hydrogen system, is about 9 per cent by weight platinum and not 5 per cent as incorrectly quoted by us".

Burden Neurological Institute: Dr. W. Ross Ashby

Referring to the note on the appointment of Dr. Ross Ashby as director of the Burden Neurological Institute, Bristol (*Nature*, January 24, p. 220), it has been pointed out to us that he will not be succeeding the retiring director, Prof. F. L. Golla, until May 1. Dr. Ross Ashby was referred to as "previously director of the Research Laboratory at Barnwood House, Gloucester"; he is in fact director of research at that Institute. For eleven years Dr. Ross Ashby was pathologist at St. Andrew's Hospital, Northampton. Among his publications is "An Introduction to Cybernetics", which has been translated into French, Spanish and Russian. In 1932 he obtained the Bronze Medal and Prize of the Royal Medico-Psychological Association, and in 1948 he obtained the Burlingame Prize (£100) offered by the Institute of Living, Hartford, Connecticut, for the best piece of original research carried out during the previous year. In 1956 he was granted a fellowship at the Center for Advanced Study in the Behavioral Sciences, Stanford, California.

Announcements

Prof. R. O. Redman, director of the Observatories in the University of Cambridge, has been elected president, for 1959–60, of the Royal Astronomical Society, in succession to Dr. W. H. Steavenson.

The Secretary of the United States Army, Mr. W. M. Brucker, has presented a replica of *Explorer* 1, the first American Earth satellite placed in orbit, together with its *Jupiter-C* carrier rocket, to the Smithsonian Institution.

Arrangements have been made by the British Council with the assistance of the Foreign Office, the Board of Trade and the Nuclear Energy Consortia for Prof. W. Murgatroyd, professor of nuclear engineering in Queen Mary College, London, to visit Venezuela, Colombia, Peru and Mexico during March 30–April 29. Under similar arrangements Prof. J. M. Kay, professor of nuclear power in the Imperial College of Science and Technology, London, is to visit Chile, Argentine, Uruguay and Brazil during March 23–April 29. They will lecture to scientists and engineers on British nuclear developments and aims, and also discuss the possibilities for future co-operation with the United Kingdom.

The Proceedings of the Fourth International Congress of Biochemistry, held in Vienna in 1958, are being published by the Pergamon Press by arrangement with the International Union of Biochemistry. The fifteen volumes include all the contributions, invited discussions, symposia and colloquia presented.

A debate, organized jointly by the Royal Institute of Chemistry (London Section), the Classical Association (London Branch) and the Haldane Society, on the motion "That the Education of our Future Rulers should be primarily in the Sciences rather than in the Humanities", is to be held in the Beveridge Hall, Senate House, University of London, on March 18. The chairman will be Sir Cyril Hinshelwood; for the motion, Sir Alexander Fleck and Prof. A. R. Ubbelohde; against the motion, Prof. B. Farrington and Prof. W. Beare.

The Plant Phenolics Group is holding a symposium on "Phenolics in Plants in Health and Disease" in the Department of Engineering in the University of Bristol on April 2 and 3. Further details can be obtained from the honorary secretary, Dr. T. Swain, Low Temperature Research Station, Downing Street, Cambridge.

The annual International Starch Convention organized by the German Cereal Research Station at Detmold is to be held in Detmold during April 21–23. It will be followed on April 24 by a special Convention to celebrate 75 years of potato research and also on April 24 and 25 there will be held at Detmold the first plenary session of the newly formed International Committee for the Standardization of Analysis of Starch and its By-products. Further information can be obtained from Dr. Eric Dux, Sichel Adhesives, Ltd., 6 Friar's Lane, Richmond, Surrey.

FUEL AND POWER IN BRITAIN

A DEBATE in the House of Lords on January 21 on fuel and power policy in Britain was opened by Viscount Hall, who questioned the policy of replacing the use of coal by oil, particularly at four of the new nuclear power stations, and also suggested that the nuclear power policy might need revision in view of the rate of development and the possibility of building stations that would rapidly be outdated. Replying for the Government, the Minister of Power, Lord Mills, said that current government policy is following the general lines endorsed by the Ridley Committee. He stressed the importance of the Scottish Gas Board's decision to construct a Lurgi plant in Fife for the total gasification of poor-quality coal; this has arisen from close co-operation between the National Coal Board and the gas industry. A similar plant is to be constructed by the West Midlands Gas Board to use deep-mined coal of poor quality, and as an outcome of co-operation between the refineries and the gas industry, surplus products from refineries are to be delivered to gas works and processed into town's gas. Coal still provides the bulk of the fuel requirements of Britain—more than 200 million tons a year—and he hoped that research and development will in due course create new demands for our indigenous coal resources. The Scientific Advisory Council of the Ministry, under the leadership of Sir Alexander Fleck, has been asked to study these possibilities.

In view of the present excess of supply over demand for coal in Britain, the Government has been strongly urged to reduce further the production of opencast coal, to restrict the increasing use of oil fuel and to scale down the nuclear energy programme. Lord Mills stressed the temporary character of the present shortage. As regards opencast coal production, the output is to be reduced by 3 million tons this year; further reduction would involve breaking contracts with an industry in which £27 million has been invested in plant for this purpose. The Government, however, does not agree that the use of oil, which now represents 15 per cent of the fuel consumption of Britain compared with 7 per cent before the War, should be restricted. This would be inconsistent both with the fuel policy of the country and with the Government's general policy of removing restrictions on international trade. The liquid methane imports mentioned by Lord Hall represent, he said, an experimental trial of the technical and economic possibilities. As regards nuclear power, Lord Mills regretted the suggestion for curtailing the programme to increase the market for small coal. Cheap and abundant power is the basis of a thriving and progressive economy. Thanks to the work of scientists and engineers, Britain leads the world in the use of nuclear energy for the generation of electricity, but we could only utilize that lead by developing an industry continuously advancing the applications of nuclear energy by designing and applying reactors and associated engineering works. This would lower capital and operating costs, to the ultimate benefit of users of electricity and, although great improvements had been made in power stations operated by coal, we should reach a stage when the cost of nuclear power would justify our programme. Any practical results from the fast breeder reactor, of the type being constructed at Dounreay, were probably 10–15 years away, and from *Zeta* still further, but they are all promising developments.

Production of phurnacite has increased to 600,000 tons a year, but there have been setbacks in the development of full-scale manufacture of the process for binding anthracite known as shape. The Coal Board is now completing a pilot installation for the underground gasification of coal at Newman Spinney, near Chesterfield, and it was hoped that gas from this installation would shortly be generating electricity in a small temporary power station erected there by the Central Electricity Board. The programme of the Board for 1958–63 would provide new installed capacity of 12,800 megawatts, of which 10,730 megawatts will be steam driven, including seventeen new stations and three extensions to consume 25–30 million tons of coal a year when in operation.

On the matter of costs the Paymaster-General, Mr. R. Maudling, said in the House of Commons, on the second reading of the Electricity (Borrowing Powers) Bill on January 20, that while the capital cost of nuclear power stations at Bradwell and Berkeley will be about three times that of a coal-fired station, that of Hinkley Point will be down to 2·5 times. The present calculation is that the Hinkley Point station, of which the capital cost will be £120 a kilowatt, as against £145 for the earlier stations, will be marginally slightly more economic than a coal-fired station operating in the same area. Assuming 5 per cent interest-rate, 20 years life for the plant and a 75 per cent load factor, he believes that by the earlier 'sixties the nuclear plant will be marginally more economical than conventional plant.

SECONDARY EDUCATION IN BRITAIN

THE Government White Paper, "Secondary Education for All: a New Drive"*, marks no real change of policy but gives some welcome assurance of continuity. The imminent but temporary decline in the school population is to be utilized to improve the quality of education, and the bulk of the new expenditure is to be concentrated on the secondary schools. By the mid-1960's the worst inadequacies of the schools will have been remedied. There will be more and better school buildings; more and better trained teachers; and smaller classes. The Government, however, considers it would be wrong to dissipate the improvement in educational standards to be secured under this immediate five-year programme by attempting too much too soon. The main objective is to encourage those young people who wish to stay on voluntarily at school beyond the minimum school-leaving age and there is nothing in the White Paper about fixing dates for measures to extend the compulsory period of education. The programme is part of a concerted drive to create an educational system adequate to meet both national and individual needs in the modern world. The keynote is opportunity for the individual boy or girl to go as far as his or her keenness or ability will allow, and the nation must grasp the opportunity to develop the educational system so that it can better fulfil its task of producing citizens who are fitted by character, knowledge and skill to play their full part in an increasingly educated and responsible democratic society.

---

* Secondary Education for All: a New Drive. Pp. 10. (Cmnd. 604.) (London: H.M. Stationery Office, 1958.) 9*d*. net.

Before outlining the specific programme, the White Paper points out that the Government does not wish to rule out experiments with comprehensive or similar schools proposed on genuine educational grounds, but is convinced that it would be wrong to abandon the grammar schools, though they alone cannot provide sufficient numbers of highly trained citizens. There is still plenty of room for experiment in the precise pattern of organization to be adopted. The widest possible range of opportunities should be provided for boys and girls of different capacities and fitness, but it is wrong to think that each school can do everything or that each type of school must have a fixed and self-contained exclusive territory.

As a first step the Government proposes to launch and carry through a continuous building programme for primary and secondary schools, rising from £55 million in 1960–61 to about £60 million in 1961–62 and costing £300 million in the five years to 1964–65. An immediate increase is being made in the volume of minor works which local education authorities and school governors can undertake, and the limit of cost is being raised from £10,000 to £20,000. The reorganization of the remaining 'all-age schools' in which are more than 150,000 pupils of eleven or more is to be completed, and resources will also be found for improving conditions in existing secondary schools. Reference is made to the improvement of science facilities, and although it is not expected to bring all secondary school buildings up to modern standards, by concentrating first on the tasks that will most quickly yield improvements it is hoped to make a big advance towards secondary education for all within the five-year programme. As regards the reduction in the size of classes, the Government's policy is first to increase the supply of teachers, and apart from the expansion of teacher training colleges already announced the Government's policy is to increase recruitment from universities also as far as is consistent with the maintenance and improvement of quality. It is determined that the size of primary classes should continue to be reduced as quickly as possible so that classes of more than forty children are virtually eliminated by the middle-1960's. A decisive general improvement in secondary school classes is also expected within the next five years. The White Paper includes a useful summary of progress under the Education Act of 1944.

THE COUNCIL FOR SCIENCE AND TECHNOLOGY OF WESTERN GERMANY

AN important event during the past year was the foundation of the *Wissenschaftrat* (Council for Science and Technology) in Western Germany. It was constituted on February 8 with the Federal President himself taking the chair, following a proposal by the president of the German Research Association (*D.F.G.*), Prof. Hess. Previously, at its annual general meeting, the Industrial Donors' Association had already welcomed the idea and stood squarely behind it from the outset. The tasks of this new body are as interesting from a purely practical as they are from an idealistic point of view. Just as interesting is its composition, reflecting all sections of academic, public and industrial life, with members who may be expected to take a large and important share in research, university teaching and training, and the application of pure and applied research in industry and commerce. The academic element, as is traditional in Germany in such matters, is in the majority—sixteen professors, all prominent nominees of the German Research Association, the Max Planck Society and the Committee of German Vice-Chancellors (*Rektorenkonferenz*). In addition to this academic core, the Federal and Land Governments delegate jointly six members, and the Federal Government alone six further leading Civil servants. The latter represent the Ministries of the Interior, Finance, Economics, Food, Transport and include a Secretary of State from the Ministry for Atomic Energy and Waterpower. Also the *Länder*, the highest education authorities, including universities, are themselves represented at ministerial level, by one delegate each, including Berlin, thus adding nine members. This adds up to thirty-seven, to which the industrialists as sponsors and donors (*Stifterverband für die deutsche Wissenschaft*) also send their honorary president and curator and six further members.

These forty-five men forming the new Council are thus a significant mixture of prominent personalities and well qualified, it would seem, to deal with their brief. This was summarized in the *Bulletin Wirtschaft and Wissenschaft*, published in the spring of 1958:

(1) The reflexion to the outside world of the unity and equality of all science, that is, of the equal importance of research, teaching and training in Germany. This Council could be described as the 'scientific conscience of the nation'.

(2) The Council will have to assess and determine the total requirements of the three tasks, research, teaching, and training, covering the whole federal area.

(3) The Council has to hold a watching brief over a proper flow of young men of promise from university institutions, industry, public life, into positions of responsibility and leadership.

(4) Reforms and developments have to be taken care of, with regard to all three aspects mentioned above, and the financial implications to be worked out in collaboration with the Ministry of Finance.

(5) A key to apportioning financial liabilities among Federal and Land governments has to be found, possibly on a quinquennial basis. (The latter point recalls the five-year period in the fiscal commitments

of the Treasury in Britain, through the University Grants Committee, and it is not improbable that the German suggestion was influenced by the British example. There is ample evidence that the latter was carefully studied.)

(6) The Council will have to smooth out inequalities and co-ordinate measures taken by the central and local governments (*Länder*, cities and districts), as regards the promotion of interest in science and research.

(7) Finally, it will be the Council's duty to scrutinize a proposal to create a central agency for the promotion of science, scholarship and research, under a federal ministry.

This is only a brief statement of the main aims for which this Council was called into being. Conditions for its proper functioning will, of course, be :

(1) The provision of adequate grants for supra-regional research institutions and projects, from the central Government and the land authorities, inasmuch as the latter cannot adequately finance them.

(2) The willingness of *Länder* governments to supplement federal funds in financing certain regional institutions.

(3) The readiness of industrial and commercial organizations to give larger sums than hitherto for the general promotion of science and for scholarships, over and above those which benefit industry directly.

(4) Parliament will have to strengthen and support the Council by accepting its advice and legislating in the light of this advice. The Council should in time achieve considerable public importance, comparable to that of the University Grants Committee.

(5) Finally, the Council should devise broad reforms for staff–student relations in institutions of higher education, for only this can ensure the vigilance necessary for 'talent-spotting' in the future.

Perhaps the most important of these points is Parliament's job of budgeting for developments in science, scholarship and technology. The first step has already been taken : annual returns have been abandoned in favour of five-year plans. A carry-over of unspent funds must obviously be permissible. Altogether, a generous, non-bureaucratic attitude seems to have been emphasized from the outset, as befits a body composed of representatives drawn from so many sources.

All members of this new Council are aware that they have to make up a good deal of lost time and, for the sake of their country's great tradition in research and scholarship, they are anxious to regain a new leading place in international science.

J. Horne

PHOSPHATES AND ORGANIC SUBSTANCES IN NITROGEN DEFICIENCY

THE International Association for Research on Phosphates, with its headquarters at 28 rue Saint-Dominique, Paris VII^e, held its third congress at Biarritz during October 21–24. Approximately one hundred scientists and chemical engineers from twenty-three countries attended the Congress, which which was on the greater utilization of phosphates.

Communications on mining phosphate rocks, their solubility, residual effects in soils, influence in plant growth and value when incorporated with organic substances were read and discussed.

Drs. L. Schmitt (Darmstadt, president of the Association), F. Van der Paauw (Gröningen), F. Scheffer (Göttingen), L. Gisiger (Liebefeld, Switzerland), Ed. Hofman (Weihenstephan, Germany), L. Wiklander (Uppsala) and G. Barbier (Versailles) considered different aspects of the solubility of natural rock phosphates when added to soils and the phosphates present in soils under various conditions.

Drs. J. Cuzin (Paris, secretary of the Association), A. Fardy (Athens), Mme. Bireska (Warsaw), Drs. S. Nicolic (Belgrade), K. Nehring (Rostock) and M. Homes (Brussels) presented their observations on drop growth fertilized by different sparingly soluble calcium phosphates and phosphate rocks. Dr. O. Arrhenius (Grödinge, Sweden) reported a favourable effect on growth of trees when fertilized by powdered rock phosphates at the rate of one kgm. per tree.

All over the world there is a tendency towards a greater utilization of basic slag, phosphate rocks and strongly heated phosphate rocks instead of superphosphate and other soluble phosphates. This is certainly good for permanent agriculture, because the basic calcium phosphates leave a greater residual effect in soils and decrease the leaching of lime from the land. Dr. G. W. Cooke (Rothamsted) reported a more marked gain in the phosphate status of land when treated with bone meal than when superphosphate was utilized in the Saxmundham experiments over fifty-six years. It is of interest to note in this connexion that Dr. S. Nordengren (Landskrona, Sweden), the leader of the superphosphate industry in Sweden, is considering the manufacture of under-acidulated superphosphate and triple superphosphates for the market.

Interesting experiments on the solubilization of rock phosphates by the action of soil micro-organisms were described by Drs. L. Meyer and Eva Köning (Hohenheim-Stuttgart) and Dr. J. Pochon and Mlle. A. Roche (Pasteur Institute, Paris).

Dr. N. R. Dhar (Allahabad) discussed the augmentation of atmospheric nitrogen fixation in soils by incorporating different phosphates, with organic substances like green manure, farmyard manure, straw, municipal waste, leaves, grass sods, sawdust, legumes, or finely divided coal dust ploughed into the soil. He also reported that when basic slags, phosphate rocks or superphosphates are added to these organic substances during the process of composting, there is more fixation of atmospheric nitrogen in light than in the dark, and that the total nitrogen contents of the phosphated composts vary from 1·6 to 2·4 per cent as against 0·6–1 per cent present in the Indore composts of Howard. In this connexion it is interesting to record that Dr. L. Borasio (Vercelli, Italy) obtained good results in rice cultivation with a mixture of powdered rock phosphate and farmyard manure. Similar observations were described by Drs. E. Bottini (Turin) and A. Zeller (Vienna).

Recently the Soil Association at Haughley (England) obtained a yield of 30·4 cwt. of barley grain per acre by ploughing in 99 lb. phosphate per acre as basic slag mixed with barley straw. The yield with 112 lb. nitrogen as ammonium sulphate added to the same amount of straw was 20·8 cwt. per acre and in the control field containing only straw the yield was 14 cwt. per acre.

That phosphates and organic matter can fix atmospheric nitrogen in the soil and supply available nitrogen, phosphate, potash, humus and trace elements is of supreme importance in meeting the nitrogen shortage in the world (see *Nature*, **164**, 597 ; 1949).

The food production in the world is estimated to be approximately 1,100 million tons, for feeding the 2,700 million people. Out of this food, about 650 million tons consist of cereals (producing 1,100 million tons of straw containing 7–8 million tons of nitrogen) and 450 million tons of other foodstuffs. As only 25 per cent of the added nitrogenous fertilizers and manures is normally recovered in crops, and the average nitrogen content of the food materials is 2 per cent, approximately 110 million tons of fixed nitrogen seem to be necessary for the food production of the world. But chemical industry is supplying only 7 million tons per year (Table 1).

Table 1. WORLD PRODUCTION AND CONSUMPTION OF FERTILIZERS, 1955–56

Region	Production (1,000 tons)			Consumption (1,000 tons)

It has been estimated that 4,000 million acres of land are available for cultivation in the world, and of this only 1,000 million acres are considered as first-class land. Consequently, if the fertilizers consumed in the world were evenly applied to the 4,000 million acres, each acre of land would receive 3·5 lb. nitrogen, 4·05 lb. phosphorus pentoxide and 3·3 lb. potassium oxide per year. It is an interesting coincidence that the fertilizers consumed in the United States per acre in 1956–57 are of the same order, that is, 4·2, 4·6 and 4·0 lb., respectively. Evidently these amounts are inadequate for intensive cultivation.

Moreover, the industrially under-developed countries find it difficult to construct nitrogen fixation factories. Table 2 shows the capital cost involved in the different types of ammonia synthesis plants for manufacturing 100 tons of ammonia per day.

Table 2. CAPITAL INVESTMENT (DOLLARS) FOR DIFFERENT TYPES OF AMMONIA SYNTHESIS PLANTS

In a study on "Observations on the Planned Provision of Nitrogen Fertilizer", Prof. Tinbergen and others of the Netherlands Economic Institute, Rotterdam, have reported that the world demand for nitrogen fertilizer in 1960–61 is expected to be 8·1 million tons (Europe, 3·1 million tons ; United States, 2·4 million tons ; other areas, 2·6 million tons). They also concluded that the consumption of nitrogen per acre of land is directly proportional to the population density of the country. This is shown in Table 3.

Table 3. NITROGEN CONSUMPTION IN 1956–57 IN KGM. PER HECTARE PER YEAR

Japan	109·6	Greece	12·1

The average of the Organization for European Economic Co-operation area is 16·8 kgm. per hectare. It has been reported that there is shortage of chemical fertilizers in the U.S.S.R. The figures for nitrogen consumption in Table 3 show that, except in Japan, Taiwan, Belgium, Iceland and Holland, the nitrogen supply to crops as fertilizers is low. Only the countries having a large population density are compelled to use large amounts of industrial nitrogenous compounds, but not enough phosphates are used for producing the required amount of cereals. Moreover, in a recent publication (1957) on "Industrial Uses of Nitrogen" by the European Productivity Agency the following lines occur : "As world nitrogen production is outstripping the expansion of demand for traditional purposes (particularly for nitrogenous fertilizer), all producers are looking round for new outlets". It appears, therefore, that due to the high cost of nitrogenous fertilizers, farmers find it uneconomical to use the required amounts of chemical nitrogen for crop production.

The other nitrogen sources are legumes, precipitation, farmyard manure, municipal refuse and garbage. It has been reported that in the United States two million tons, and in the whole world five million tons, of nitrogen are fixed by the legumes in the soils of the Earth. Rain, snow and hail supply about 4–5 lb. per acre, that is, about 10 million tons of available nitrogen fall on the 4,000 million acres of agricultural land in the world, but a good deal is wasted as run-off. According to the U.S.A. Department of Agriculture, the world produces 1,400 million tons of manure containing 7–8 million tons of combined nitrogen, but only 15 per cent of this is actually utilized in cultivation. All over the world there is an attempt to prepare composts from city refuse and sewage sludge, which contain approximately 5 million tons of total nitrogen per year, but only a very small amount is actually reclaimed at present.

As the world reserves of phosphate rocks are not less than 21,000 million tons (United States, 7,000 million tons ; U.S.S.R., 6,500 million tons ; North Africa, 5,000 million tons ; other areas, 2,500 million tons) and the annual consumption has been estimated to be 30 million tons by R. Saint Guilhem, technical director-general of the North African Phosphate Company, the natural rock phosphates should, at the present rate of consumption, last for at least 700 years. Consequently, a much greater application of these phosphatic materials, and basic slag from the expanding world steel industry, mixed with organic waste, would be of great value to permanent agriculture in all parts of the world.

MEASUREMENTS AT LEEDS FOLLOWING THE WINDSCALE REACTOR ACCIDENT

From the Department of Medical Physics, University of Leeds, The General Infirmary, Leeds, 1

Iodine-131 in Human Thyroids and Iodine-131 and Cæsium-137 in Milk

By Dr. P. R. J. BURCH

FOLLOWING the announcement of the Windscale reactor accident of October 10, 1957, an apparatus was assembled to measure the trace uptake of iodine-131 in human thyroids and the concentrations of iodine-131 and cæsium-137 in milk.

A 4-in. dia. × 2½-in. sodium iodide (thallium) crystal was optically coupled to a 5-in. diameter photomultiplier, the output from which was fed via a cathode-follower and a linear pulse-amplifier to an *MkI* 'Sunvic' pulse-analyser operated on its 60-channel range. The resolution obtained for the cæsium-137 photopeak was 14 per cent. Measurements were made inside a steel room, with walls and ceiling 9 in. thick, and a 12-in. thick floor, affording excellent attenuation of local γ-rays. The crystal-photomultiplier assembly was mounted on a bracket of adjustable height, and in the thyroid investigations the centre of the crystal was placed opposite the thyroid of the seated subject, so that the spacing between the crystal casing and the anterior skin surface over the thyroid was within the range of 1–2 in. Short separations were chosen to give the requisite high sensitivity, although this involved a sacrifice in calibration accuracy due to the uncertainties in the size and exact location of the thyroid. Calibration was performed at various separations with a mock thyroid, consisting of an iodine-131 solution in a glass bottle inserted in a wax 'neck' between the head and trunk of a water-filled 'phantom'.

Detailed γ-ray spectra over the energy-range 0·05–1·0 MeV. were taken in several cases, but due to the time-consuming nature of this operation it was not possible to employ it throughout, and in the remaining cases only the total count-rate for the energy-range 0·05–1·0 MeV. was recorded. Corrections for the contribution given by the cæsium-137 and potassium-40 contents of the body were deduced from detailed spectra. From experiments with a phantom, it was estimated that the count-rate from iodine-131 distributed through the body was less than 1 per cent of that from the thyroid, and consequently this small correction was ignored.

The results for the iodine-131 contents measured in human thyroids are summarized in Table 1 and the series of observations for subjects *A* and *B* are plotted in Fig. 1.

For the milk measurements, 1-pint bottles were clamped in a standard position against the end of the crystal casing, the axis of the bottle being at right angles to the crystal axis. Detailed γ-ray spectra were observed for a few samples, and corrections were derived for the potassium-40 contents of milk and bottle. The following response-rates for the energy-range 0·05–1·0 MeV. were determined: potassium-40 content of milk and bottle, 0·8 c.p.s.; 1·0 nc. (1 nc. = 10^{-9} curie) iodine-131, 3·6 c.p.s.; 1·0 nc. cæsium-137, 2·6 c.p.s. In the early samples the cæsium-137 contribution to the total counts was small compared with that from iodine-131 (Table 2); in the later samples, potassium-40 and cæsium-137 contributed, on the average, approximately 1 c.p.s. Where the cæsium-137 content was not directly determined from the detailed spectrum, the iodine-131 content was calculated by assuming that potassium-40 and cæsium-137 jointly contributed 1 c.p.s.

The milk results are summarized in Table 2, and the results for suppliers—one of the Leeds multiple dairies and the farm at Farsley—are plotted in Fig. 2. For the period October 16–25 the decrease of the iodine-131 content in milk samples from these suppliers was roughly exponential (there is evidently some alteration in the routine for milk delivered on a Saturday from the first suppliers) and the effective 'half-period' was approximately 3 days. Over the period October 26–November 13 the decrease in content was less rapid, the effective 'half-period' for samples from the above two suppliers being approximately 5·5 and 5·2 days, respectively.

The results are too few and too scattered for reliable generalizations concerning the iodine-131/cæsium-137 ratios in milk. The average for samples delivered on October 16 and 17 was 16 with extremes of 6 and 50. On November 6 and 7 this average ratio had fallen to 2·9. If the change in ratio had been due simply to the difference in physical decay of the two nuclides, the expected ratio on November 6 and 7 would have been 2·6.

This increase in cæsium-137 intake above that due to world-wide fall-out should have produced a significant increase in the body burden and this was, in fact, observed. In early 1957, the total body burden of cæsium-137 in subject *A* was 4·9 nc., but on April 1, 1958, this had risen to 11·5 nc. Assuming an effective half-life of 140 days[1] for

T	Resident in Cambridge until November 2 p.m.

For explanation of abbreviations see Table 2.

cæsium-137 in the body, it is estimated that there should have been an increase on this date of about 5 nc. due to the additional intake of cæsium-137 from the Windscale incident, through milk alone. Over the same period, the cæsium-137 body burden of subject *B* rose from 7·9 nc. to 19·5 nc.

Fig. 1, showing the initial rise and subsequent fall in the iodine-131 contents of the thyroids of subjects *A* and *B*, reveals clearly the connexion with the Windscale incident. Iodine-131 has been detected in human thyroids after nuclear weapon tests[2]; but the maximum uptake observed was of the order of

10^{-10} c., in contrast with the maximum uptake of the order of 10^{-8} c. reported here.

Where the intake of iodine-131 from milk can be estimated, a close association with the uptake of iodine-131 in the thyroid is observed. It is interesting to note that subjects *J* and *K*, who had been in the Keswick area of the Lake District until October 17, had appreciably lower iodine-131 uptakes than Leeds residents—an illustration of the effect of wind directions during and after release of activity from the pile. Subject *T*, who until the afternoon of November 2 had been resident in Cambridge, had a thyroid content of less than 10^{-9} c. iodine-131 when measured on November 3.

An attempt was made to estimate the fraction of iodine-131 taken up by the thyroid of subject *A* and its effective half-life, by relating the observed uptake to the estimated intake through milk. (Although milk was undoubtedly the main source of iodine-131, it is possible that it was not the only one.) Reasonable agreement (Table 3) was obtained for a thyroid uptake of 44 per cent and an effective half-life for iodine-131 in the thyroid of 7 days. Both figures are rather high for a normal subject, but the exact intake of milk was somewhat uncertain and, furthermore, the response was sensitive to the thyroid-detector geometry. However, a value of 8·5 nc. measured for this subject on November 1 at the Radiological Protection Service, Sutton[3], is slightly greater than the value of 7·5 interpolated from the smooth curve of Fig. 1 (although a straight line drawn through the points for October 31 and November 2 intersects the ordinate for November 1 at 8·5 nc.).

The dose to subject *A*'s thyroid tissue was calculated by performing a numerical integration for the period October 13–27 and assuming that the decay of activity from October 28 to infinity was exponential, with an effective half-life of 9·6 days. Assuming a thyroid mass of 30 gm. and that the γ-dose was 10 per cent of the β-dose, the total (β + γ) dose was $0{\cdot}09_5$ rad. A similar calculation for subject *B* gave a total (β + γ) dose to thyroid tissue of $0{\cdot}09_1$ rad.

Table 3. COMPARISON BETWEEN MEASURED UPTAKE OF IODINE-131 IN THE THYROID OF SUBJECT *A*, AND CALCULATED UPTAKE, ASSUMING AN AVERAGE INTAKE OF 1·2 PINTS MILK DAILY FROM A LEEDS MULTIPLE DAIRY (*MA*), AN IODINE-131 UPTAKE OF 44 PER CENT IN THE THYROID AND AN EFFECTIVE HALF-LIFE FOR IODINE-131 IN THE THYROID OF 7 DAYS

Date	Observed uptake (in units of 10^{-9} c. iodine-131)	Calculated uptake (in units of 10^{-9} c. iodine-131)	Date	Observed uptake (in units of 10^{-9} c. iodine-131)	Calculated uptake (in units of 10^{-9} c. iodine-131)

29	9·8	10·1	14	3·3	

These doses are about the same as the soft-tissue dose received in one year from natural sources of radiation[4] (predominantly local γ-rays, potassium in tissue and cosmic rays). Thyroid doses for adult Leeds residents drinking about one pint of milk daily from the Farsley farm would have been about 0·2 rad and adult Skipton residents would have received some 0·3–0·5 rad. Since the uptake of iodine-131 in the thyroid of subject *N* (4-year-old Leeds boy drinking milk from one of the Leeds multiple dairies) is about the same as for adults drinking similar quantities of the same milk, the dose to his thyroid tissue will be higher (by about four times), in inverse ratio to the thyroid masses.

I am a member of the External Scientific Staff of the Medical Research Council, and am indebted to Mr. D. B. Appleby for extensive assistance with these observations.

Increase in Background Gamma-Radiation and its Correlation with Iodine-131 in milk

By PROF. F. W. SPIERS

MEASUREMENTS of the γ-ray dose-rate over a lawn and in a house in Leeds had been made during August and September 1957 and it was possible to repeat the measurements on October 19, 1957, and to continue them for some months thereafter. Small, but significant, increases in dose-rate above the summer values were observed in October and it is interesting to consider their relation to the iodine-131 activity in Leeds milk reported in the previous communication.

The measurements were made with a portable high-pressure ionization chamber having long-term stability of response. The chamber, which has a steel wall 0·12 in. thick, operates with a gas filling of 50 atm. of nitrogen, and the change of potential of the central electrode is measured by applying a balancing voltage to the grid of a miniature triode in a Townsend balancing circuit. A drift of 1 V. corresponds to a dose of 0·092 µrad of radium γ-radiation and to 0·108 µrad of γ-radiation from iodine-131. A background γ-ray dose-rate of the order of 10 µrad per hour can be measured with a standard error of ± 1·5 per cent in a single observation of 3–4 min. The standard error of the observations reported here (means of 5 or more readings) is about ± 0·5 per cent.

The stability of response of the instrument is indicated by calibrations carried out with a standard radium source at a dose-rate of approximately 12 µrad/hr., which is of the same order as that from local γ-radiation. The '4π' calibration thus obtained in a large hall, under conditions of minimum scatter, was 0·092 µrad/V. in July 1957, and 0·093 and 0·094 µrad/V., respectively, in April and May 1958. The instrument response to radiation (mainly cosmic) in the Leeds steel room (see previous communication) was 0·465, 0·496, 0·517 and 0·493 V./min. on dates in July, October 1957 and March, May 1958, respectively. The radiation-level in the steel room is unaffected by adventitious changes in the local γ-ray intensity outside it; but the cosmic-ray ionization under the 9-in. steel shielding shows a variation with barometric pressure of − 3 per cent per cm. mercury. Apart from this effect, the response of the instrument in the steel room reflects the stability of the grid current of the electrometer valve which, at 1·9 × 10^{-15} amp., is equivalent to 2 per cent of the current obtained for a typical background γ-ray level. Tests showed that leakage across insulators was insufficient to cause a significant error in the instrument response.

Measurements made at intervals from August 1957 onwards are shown in Fig. 3 for a point 1 ft. above a small lawn, surrounded on three sides by garden but relatively close to the building line, and also for a point in the centre of a ground floor room facing the garden. The results show that, on October 19, 1957, the instrument response over the lawn was 0·23 V./min. above the summer value of 1·75 V./min., corresponding to an increase in γ-ray dose-rate of 1·36 µrad/hr. or about 12 mrad/year. The increase in dose-rate indoors was rather less than half this amount. After falling from the high values of October 19, the γ-ray dose-rates over the lawn and in the house then showed a more or less continued rise which levelled off in the spring of 1958; the relation of these later observations to possible bomb fall-out is the subject of a separate investigation. There can be little doubt that the sharp rise and fall of dose-rate shown in October 1957 was caused by deposition from the Windscale cloud. It is known from Chamberlain[1] that the escape of radioactivity from the reactor was mainly iodine-131 with at first a considerable fraction of the 3·2 day isotope tellurium-132 and its decay product iodine-132; small percentages of other γ-ray emitters, cæsium-137, rubidium-103 and zirconium-95 – niobium-95, were also present. It can thus be estimated that, of the total increase in γ-ray dose-rate of 1·36 µrad/hr. on October 19, 0·6 µrad/hr. was attributable to the isotope iodine-131.

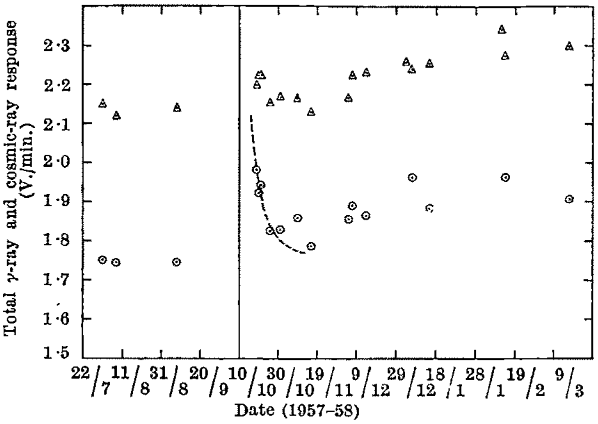

Fig. 3. Total response of a high-pressure ionization chamber to cosmic radiation, local γ-radiation and γ-radiation from adventitious radioactivity. △ over a lawn; ⊙ in a house. The dotted curve indicates the expected decay of the response for the iodine-131, tellurium-132, iodine-132 and other isotopes in the Windscale deposit

The relationship between the observed γ-ray dose-rates and the milk activity in Leeds can be compared with deductions from observations of the higher dose-rates and milk activities made in Cumberland by the Atomic Energy Authority. In order to compare directly with the Cumberland observations, however, some allowance must be made for the fact that the Leeds measurements were in a built-up area where the ionization chamber was screened from a considerable fraction of the radiation it would have received in open country. Chamberlain[1] has shown that the dose-rate at 1 m. above a circular area of radius 10 m. contaminated with iodine-131 is only 40 per cent of that from an infinite plane. It can be deduced that at the Leeds site, at about 3 m. from the building line, the observed dose-rate would be some 60 per cent of that for similarly contaminated open country. In addition to this shielding effect, the deposition of radioactivity would be affected to some extent by the 'shadowing' of near-by buildings. A very approximate factor of 2 has therefore been introduced at this stage, as an adjustment, before comparing the Leeds and Cumberland observations. In the following three comparisons the 'open country' dose-rates for the Leeds area on October 19 have been taken to be 2·7 µrad/hr. for the total increment in the γ-ray dose-rate and 1·2 µrad/hr. for the iodine-131 fraction.

(1) Calculations by Chamberlain[1] give the dose-rate over a uniformly contaminated plane as 7·7 µrad/hr. at 1 ft. for a contamination of 1µc. iodine-131 per $m.^2$. The iodine-131 dose-rate of 1·2 µrad/hr. corresponds, therefore, to a contamination of about 160 nc. iodine-131/$m.^2$ on October 19 and hence to 200 nc./$m.^2$ on October 16, on which date other measurements are available. The activity on the grass itself is about one-third of this (see below) and a figure of the implied magnitude, ~ 70 nc./$m.^2$, fits in with the nearest reported grass activities of 81 nc./$m.^2$ at Sheffield and 169 nc./$m.^2$ farther west at Burnley[2] on October 16.

(2) Chamberlain[1] reports a ratio of grass activity/ground activity of 0·16 on October 28 and it can be inferred from this and other results in his paper that the ratio was about 0·3 on October 19. Furthermore, a milk activity of 1 µc./l. was found to be associated with a grass activity of 11 µc./$m.^2$. It follows that a ground contamination of 160 nc/$m.^2$ in Leeds on October 19 should yield a milk activity of about 4·3 nc./l.

(3) A further empirical relationship evident in the Atomic Energy Authority results indicated that a milk activity of 1 µc./l. was associated with a γ-ray dose-rate of 0·45 mrad./hr. at 1 ft. above open ground.

The increment in the γ-ray dose-rate in Leeds of 2·7 μrad/hr. on October 19 would be associated, on this basis, with a milk activity of 6·0 nc./l. This expected value and that in (2) are in reasonable accord with the iodine-131 contents of Leeds milks which on October 20 ranged from 2·5 to 10·5 nc./l. with a mean of 7 nc./l.

It is evident from these comparisons that, with the introduction of a factor 2 for the shielding in the built-up area, the ratios of the γ-ray dose-rates to the milk activities, measured at trace-levels in Leeds, are in substantial agreement with those observed at levels some hundred times greater in Cumberland.

In addition to comparisons with similar observations by the Atomic Energy Authority, it is of interest to see to what extent the results of the milk and γ-ray measurements fit in with theoretical estimations based on the cow's known grazing habits and its metabolism of iodine. The basic data required[3] are the average area grazed by a cow per day and the iodine-131 level in cow's milk on the days following the ingestion of a known quantity of that isotope[4]. A relationship between the activity on the ground and the fraction retained by the grass must also be known; this can be based on measurements given by Chamberlain[1] for October 28. It is to be expected that this fraction must change with time and there is experimental evidence for this in Fig. 4 of Chamberlain's paper, where the ratio of ground iodine-131 activity to the milk activity increases with time. If, following Chamberlain's data, the ratio of grass to ground activity is assumed to be 0·45 on October 11, and falling to 0·3 on October 18, the ground contamination of 160 nc./m.[2] given above for October 19, together with the biological data, would lead to an expected milk activity of 48 nc./l.—a value some seven times higher than the mean observed in Leeds. Other calculations, on the basis of a grass/ground fraction of 0·16 on October 18 and a half-period of 3 days for iodine-131 on grass (as was observed for Leeds milk), lead to lower values for the milk activity, but such assumptions would seem to be less plausible.

Neither the Leeds observations, nor, by inference, those of the Atomic Energy Authority, would seem to fit the biological data at all well, but it is scarcely to be expected that any close correlation would be shown when milk is drawn from a wide area and the autumn feeding regime is likely to be very variable. Further experimental investigations of the relation between grass contamination and ground γ-ray dose-rate and its variation with time after deposition would, however, appear to be very worth while.

I am indebted to Mr. D. B. Appleby and to Mr. R. Corry for assistance in the design of the portable high-pressure ionization chamber and for its construction.

VITAMIN B$_{12}$ AND PROTEIN BIOSYNTHESIS

Vitamin B$_{12}$ and Biosynthesis in Chick Liver

By Dr. M. J. FRASER and Dr. E. S. HOLDSWORTH

National Institute for Research in Dairying, Shinfield, Nr. Reading

In recent years evidence has been produced that the steps of incorporation of amino-acids into proteins include: (i) an activation dependent on adenosine triphosphate of the amino-acids through the COOH group, with the formation of an amino-acid–adenosine monophosphate complex by means of enzymes present in the soluble cell-sap; (ii) stabilization of the activated amino-acid by the transfer to a ribonucleic acid of low molecular weight present in the soluble cell-sap; (iii) a transfer dependent on guanosine triphosphate of the amino-acid to the microsomal ribonucleoprotein where peptide bond-formation apparently takes place.

A microsome-rich preparation which contains all the necessary components for these steps of incorporation was prepared by Wagle, Mehta and Johnson[1] from the livers and spleens of vitamin B$_{12}$-deficient and normal rats. They found that the deficient preparations incorporated less carbon-14 labelled methionine, alanine or phenylalanine into protein. Addition of vitamin B$_{12}$ *in vitro* significantly increased incorporation into both deficient and normal preparations. In a later paper[2], these workers suggested that vitamin B$_{12}$ is associated with the enzymes concerned with the activation of the amino-acids.

The purpose of this communication is to report on observations we made with preparations from normal and deficient chick livers, which have led us to different conclusions.

Experimental methods. All the chicks used in this work were hatched from eggs from hens given an all-vegetable diet deficient in vitamin B$_{12}$ and were maintained for 4 weeks as described by Coates, Harrison and Kon[3]. Typical weights at 4 weeks were: deficient birds, 120 gm.; control birds (receiving vitamin B$_{12}$ 1 μgm./100 gm. diet), 200 gm.

The carbon-14 labelled amino-acids and phosphate (^{32}P) were obtained from the Radiochemical Centre, Amersham. Vitamin B$_{12}$ labelled with cobalt-60 was kindly provided by Dr. E. L. Smith, of Glaxo Laboratories, Ltd.

We are grateful to our colleague, Dr. M. E. Gregory, for the microbiological assays of vitamin B$_{12}$, which were made with *Lactobacillus leichmannii* (Gregory)[4].

Determinations of cobalt-60 were made in a well-type, activated sodium iodide crystal scintillation counter. Standards were counted at the same time and all results are expressed as micrograms of vitamin B$_{12}$. All carbon-14 and phosphorus-32 samples were counted in a 'Tracerlab' gas-flow counter. The counts recorded here are presented as counts/min./cm.^{2} at infinite thickness, corrected for background.

The chicks were killed by breaking the neck. Livers were quickly excised and plunged into ice-cold 0·25 *M* sucrose, or medium *A*[5]. After cooling for a few minutes, they were dried rapidly on filter paper and minced with an ice-cold metal mincer. The mince was then suspended in 2·3 volumes of medium *A*, or 3·0 volumes of 0·25 *M* sucrose, buffered or unbuffered according to the particular needs of the experiment. The suspensions were homogenized in a Potter–Elvehjem homogenizer having a loose-fitting

Table 1. Distribution of Cobalt-60-B_{12} in Chick Livers

Cell fraction	mμgm. Cobalt-60 vitamin B_{12}	Percentage of total
Debris	11·6	58·8
Mitochondria	0·75	3·8
Microsomes	0·93	4·7
Supernatant	6·5	32·8

(ii) *p*H 5 supernatant	5·3	26·9

nylon pestle, six passes at approximately 1,000 rev./min. being made within 20 sec. The cell fractions were then separated by differential centrifugation for 10 min. at 700*g*, to sediment debris and nuclei, for 10 min. at 7,000*g* for mitochondria and for 1 hr. at 105,000*g* to sediment microsomes. The *p*H 5 enzymes were prepared essentially as described by Hoagland, Keller and Zamecnik[6], washed once with approximately 10 volumes of ice-cold 0·15 potassium chloride and the precipitated *p*H 5 enzymes redissolved in a volume of the appropriate medium equivalent to the weight of tissue used in the preparation. Under these conditions the concentrations of protein (10–15 mgm./ml.) and of soluble cell-sap nucleic acid (2·5–3 per cent of the protein) from both B_{12}-deficient and normal chick livers were the same. The concentration of soluble cell-sap nucleic acid was determined by the method of Hoagland, Stephenson, Scott, Hecht and Zamecnik[7].

The protein samples for counting were isolated by precipitation with 10 per cent trichloracetic acid containing 1 per cent of appropriate carrier. The precipitates were afterwards put through the twelve-stage procedure described by Simkin and Work[8]. The total *p*H 5 fraction, consisting of *p*H 5 protein with soluble cell-sap nucleic acid, was precipitated in ice-cold 5 per cent trichloracetic acid containing 1 per cent carrier, washed twice with ice-cold 5 per cent trichloracetic acid, then with 95 per cent ethanol, acetone, ethanol/ether (3 : 1) and finally ether.

Vitamin B_{12} in Chick Livers and its Distribution in the Cells

The vitamin B_{12} content of the deficient chick livers used in these experiments ranged from 0·012 to 0·017 μgm./gm. fresh liver, whereas those of control birds contained 0·077–0·090 μgm./gm. Only a small proportion (approximately 10 per cent) of the vitamin was found in the *p*H 5 enzymes isolated from these livers; for example, the *p*H 5 enzymes from 1 gm. fresh deficient liver contained 0·8 mμgm. vitamin B_{12} and those from 1 gm. normal liver, 7·0 mμgm. vitamin B_{12}. To study the distribution of vitamin B_{12}, three deficient chicks, average weight 120 gm., were given two intramuscular injections of 1 μgm. cobalt-60 vitamin B_{12} (= 0·24 μc.), one 48 hr. and the other 24 hr. before removal of the livers. The livers were pooled, minced and cell fractions prepared. The distribution of cobalt-60 radioactivity, which is assumed to be vitamin B_{12}, is shown in Table 1. The deficient livers, which would probably contain approximately 15 mμgm./gm. of 'natural' vitamin B_{12}, took up another 20 mμgm./gm. of the vitamin; but, contrary to the findings of Wagle *et al.*[2], the *p*H 5 enzymes contained only a small proportion, 5·9 per cent, of this additional vitamin B_{12}. The largest amount of the vitamin was found in the cell supernatant fraction. Very similar results were obtained by incubation of 3 gm. deficient liver mince from similar birds with 2 μgm. cobalt-60 vitamin B_{12} *in vitro*. Therefore, there seems no reason for describing the *p*H 5 enzymes as the "vitamin B_{12} enzyme"[2].

In vitro Incorporation of Amino-acids in Chick Liver

(i) *Mince experiments.* Immediately after mincing, 3-gm. portions of deficient or normal livers and 9 ml. ice-cold Krebs–Ringer bicarbonate–glucose buffer[9] were put into Krebs pots. The buffer contained 0·25 *M* sucrose and 2 μc. carbon-14 *Chlorella* hydrolysate (specific activity 60 μc./mgm.). The samples were incubated at 38° C. in a Warburg bath with gentle shaking and continuous gassing with oxygen + 5 per cent carbon dioxide. After appropriate intervals the flasks were removed and kept in an ice-bath. The mince suspensions were homogenized in their medium, cell fractions separated and counted.

In all, four mince experiments were carried out. In two there was a slight effect of addition of vitamin B_{12} to deficient livers and in the other two no effect. The results are shown in Table 2. In Table 2*A* it is shown that the deficient livers incorporated less carbon-14 amino-acids into cell debris, mitochondria and supernatant proteins, although there was no difference in incorporation into microsomes, which is taken to be the first site of peptide bond formation. In these two experiments with deficient livers when vitamin B_{12} had an effect, the incorporation increased up to the level of that in control livers without affecting incorporation into microsomes. The other type of situation encountered is shown in Table 2*B*. Here the deficient livers incorporated less amino-acids into cell fractions, including microsomes, but addition of vitamin B_{12} had no effect on the incorporation.

In view of the variable results obtained with the minces, we examined microsome-rich and pH 5 enzyme systems.

(ii) *Microsome-rich fractions.* The microsome plus supernatant fraction, prepared from a homogenate of liver mince with 3 vol. of 0·25 *M* sucrose, was incubated together with the carbon-14 amino-acid (final concentration usually 0·5 μc./ml.), magnesium ions, adenosine triphosphate buffer at pH 7·4, and with potassium 3-phosphoglycerate as described by Simkin and Work[10]. Incubation was at 38° with vigorous gassing with either nitrogen + 5 per cent carbon dioxide (anaerobic) or oxygen + 5 per cent carbon dioxide (aerobic), and samples were taken at 0, 20 and 40 min. for precipitation with 10 per cent trichloracetic acid containing 1 per cent carrier to give microsome-rich protein fraction or for dilution with ice-cold 0·25 *M* sucrose, containing 0·005 *M* carrier amino-acid, from which the microsomes were separated by centrifugation.

With carboxyl-labelled DL-alanine the effect of graded amounts of cyano- or hydroxo-cobalamin on incorporation into microsome-rich protein was studied and the results are shown in Table 3. With this amino-acid, in two experiments, we obtained greater incorporation into the deficient preparations, and *in vitro* addition of *both* forms of the vitamin slightly increased incorporation into deficient preparations.

The generally labelled amino-acids of *Chlorella* hydrolysate were incorporated to the same extent into the microsome-rich protein of deficient and normal chick livers (Table 4). Vitamin B_{12} added *in vitro* to deficient preparations was without effect (two experiments) and there was no difference in incorporation in aerobiosis or anaerobiosis. Table 5 shows the incorporation of carbon-14 L-leucine into microsomal proteins, and in this instance there was less incorporation into deficient preparations; but again vitamin B_{12} had no effect on the amount of incorporation. The anilide of the monocarboxylic acid prepared from vitamin B_{12}[11,12], which has a growth inhibition index for *E. coli* 113/3 of 2,000, had a very slight depressing effect on incorporation when used at a high concentration of 280 μgm./ml. Dr. M. E. Coates (personal communication) has found that this substance antagonizes the growth of chicks. Chloramphenicol at a bactericidal concentration (200 μgm./ml.) did not inhibit incorporation. This phenomenon has been noted by other workers in mammalian systems (for example, rat liver and guinea pig mammary gland, Fraser, M. J., Shimizu, H., and Gutfreund, H. G., unpublished work) and suggests that the reported incorporations are not due to bacterial contamination. In further experiments with leucine, vitamin B_{12} and the anilide did not alter the amount of amino-acid taken up; but in these experiments there was no difference between normal and deficient preparations.

Amino-acid Activation

(i) *Hydroxamate test.* The particle-free supernatant fraction was used to follow the rate of formation of amino-acid hydroxamate essentially as described by Hoagland, Keller and Zamecnik[6]. The incubation mixture contained 5 ml. 2 *M* salt-free hydroxylamine, 1 ml. 0·01 *M* magnesium potassium adenosine triphosphate (MgK_2ATP), 2 ml. complete amino-acid mixture giving in the medium a 0·02-*M* concentration of each amino-acid, 1 ml. 1 *M tris* buffer pH 7·6 and 1 ml. cell-supernatant proteins. The blank control contained everything except the amino-acid mixture, and the substantial colour obtained in it was due to formation of hydroxamate by endogenous amino-acids and other compounds in the supernatant fraction.

Three experiments on the formation of hydroxamate were carried out and the results of one are shown in Fig. 1. In all experiments the deficient supernatant fraction had a rate of formation of hydroxamate, that is, of amino-acid activation, nearly twice that of the normal preparation, and it was not changed by *in vitro* addition of vitamin B_{12}.

(ii) *Pyrophosphate exchange.* A dilution of the pH 5 enzyme 1 : 10 with *tris* buffer pH 7·6 was used to measure the adenosine triphosphate–phosphate (^{32}P) exchange. The final incubation mixture contained 0·002 *M* adenosine triphosphate, 0·002 *M* phosphate (^{32}P), 0·01 *M* magnesium chloride, 0·5 mgm./ml. of pH 5 enzyme, 0·1 *M tris* buffer pH 7·6 and a single amino-acid, 0·001 *M*, either alanine, leucine or tryptophan. After incubation at 37° C. for various lengths of time, 3-ml. samples were taken into

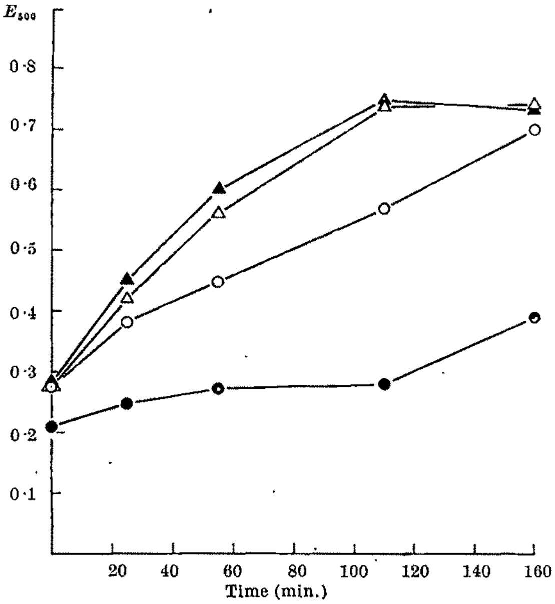

Fig. 1. Formation of hydroxamate in chick liver supernatant fractions

Hydroxamate formed after incubation of cell supernatant with a complete mixture of amino-acids. △, Deficient-liver supernatant; ▲, deficient-liver supernatant + 200 μgm. B_{12}/ml.; ○, normal liver supernatant; ●, blank, that is, without amino-acid mixture

7 ml. 10 per cent trichloracetic acid. The precipitated protein was removed and the adenosine triphosphate (^{32}P) was adsorbed on 100 mgm. activated charcoal as described by Crane and Lipmann[13] and counted.

In duplicate experiments using alanine and leucine, there was no significant difference between deficient and normal *p*H 5 enzymes, in the amount of phosphate (^{32}P) exchange. Vitamin B_{12} added to the deficient enzyme had no effect on the system, as can be seen in Table 6. However, addition of 2 mgm. of the anilide of vitamin B_{12} to the normal enzyme did depress the amount of exchange, in confirmation of the report of Wagle *et al.*[2]. Vitamin B_{12} even at high concentration only partially reversed this inhibition. Omission of the amino-acid from the incubation mixture had little effect on the exchange. Since the amount of endogenous amino-acid left on the washed and diluted *p*H 5 enzyme was probably very small, the pyrophosphate exchange may not have been measuring amino-acid activation. That the reaction was enzymic is shown by its inhibition by 10^{-4} *M* *p*-chloromercuribenzoate.

Table 6. PYROPHOSPHATE EXCHANGE INTO ADENOSINE TRIPHOSPHATE USING *p*H 5 ENZYMES FROM NORMAL AND DEFICIENT CHICK LIVER
Final medium contained: L-leucine, 0·001 *M*; MgK_2ATP, 0·002 *M*; $P^{32}P$, 0·002 *M*; Mg^{2+}, 0·01 *M*; *tris* buffer, 0·1 *M* *p*H 7·6 and *p*H 5 enzyme

*p*H 5 enzymes gave final protein concentration 0·35 mgm./ml. normal and 0·39 mgm./ml. deficient. The concentration of soluble cell-sap nucleic acid was 0·010 mgm./ml. for normal and 0·011 mgm./ml. for deficient

Vitamin B_{12} added at 200 mμgm./ml. and the anilide of vitamin B_{12} at 200,000 mμgm./ml.

30	0·50	20·1	12·7	22·5	22·6

(iii) *Incorporation of carbon-14 amino-acids into p*H *5 enzymes.* The *p*H 5 enzymes were dissolved in a buffered medium similar to that described by Keller and Zamecnik[5] containing 0·35 *M* sucrose, 0·035 *M* potassium bicarbonate, 0·025 *M* potassium chloride, 0·01 *M* magnesium potassium adenosine triphosphate, and 0·5 μc./ml. carbon-14 amino-acid. Incubation was at 37° C. for various times. The total labelled *p*H 5 fraction (that is, soluble cell-sap nucleic acid + protein) and also the labelled *p*H 5 protein were isolated. Three experiments with carbon-14 generally labelled L-leucine and one experiment with carbon-14 *Chlorella* hydrolysate gave very similar results. Fig. 2 shows results with leucine. In all experiments the deficient *p*H 5 enzyme, in spite of its lower vitamin B_{12} content, became labelled faster than the normal *p*H enzymes, the rate in some experiments being at least double. The effect was tried of a number of substances on the rate of incorporation. Neither the anilide derivative of vitamin B_{12} nor

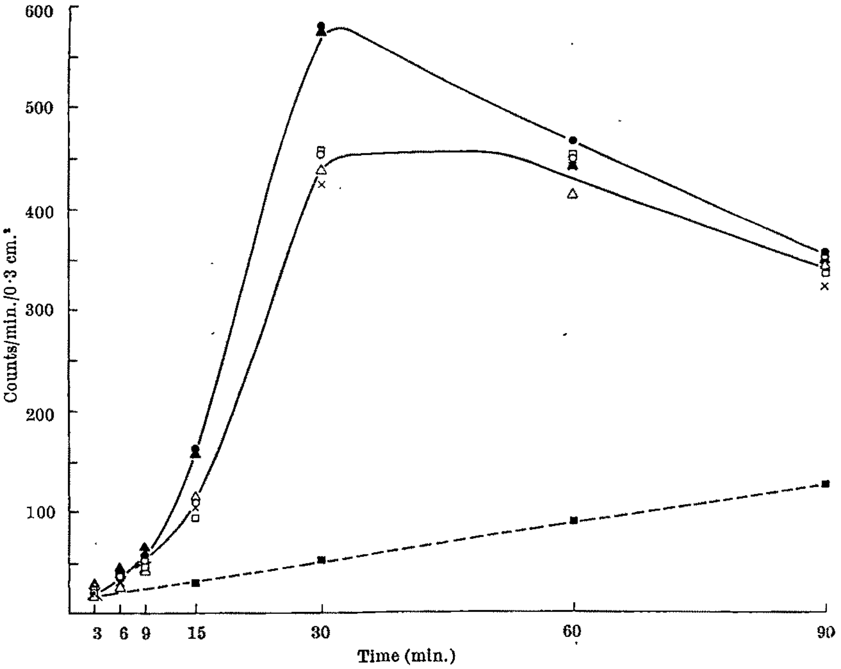

Fig. 2. Incorporation of carbon-14 L-leucine into *p*H 5 enzyme of chick liver *p*H 5 enzyme in medium *A* (ref. 5) with 0·5 μc. carbon-14 leucine/ml. Final concentration of soluble cell-sap nucleic acid of both enzymes was 0·25 mgm./ml. ○, Normal *p*H 5 enzyme; □, normal *p*H enzyme + 250 mμgm./ml. vitamin B_{12}; △, normal *p*H 5 enzyme + 50 μgm./ml. methylamide of vitamin B_{12}; × normal *p*H 5 enzyme + 50 μgm./ml. coenzyme A; ●, deficient *p*H enzyme; ▲, deficient *p*H 5 enzyme + 250 mμgm./ml. vitamin B_{12}; ■, protein fraction of *p*H 5 enzymes. All the points of the above six treatments coincide for the proteins alone

the corresponding methyl amide had any effect on the normal enzymes, and vitamin B_{12} itself did not affect deficient or normal preparations. Vitamin B_{12} deficiency often leads to an elevated level of coenzyme A in liver[14], which it was thought could account for the increased incorporation in deficient liver, since Airth, Rhodes and McElroy[15] have shown that coenzyme A can activate certain amino-acids via the carboxyl group in a manner analogous to acetate activation. However, it can be seen that coenzyme A did not increase the rate of incorporation of the normal *p*H 5 enzyme fraction. The proteins present in the *p*H 5 enzyme became labelled linearly to a final 26 per cent of the total carbon-14 in the soluble cell-sap nucleic acid plus protein fraction. Fig. 2 shows that both enzymes and the various treatments lead to the same amount of labelling in these proteins.

Discussion

For our study of the distribution of vitamin B_{12} in liver, we preferred to use deficient chicks, that is, chicks with depleted vitamin B_{12} stores, and inject a dose of cobalt-60 vitamin B_{12} smaller than that used by Wagle *et al.* for normal rats. A further difference was that our dose was given in two portions 48 hr. and 24 hr. before the liver was excised, allowing a greater chance for equilibrium to be established. In this way we found that most of the vitamin was in the *p*H 5 cell supernatant, and hence there was no reason for associating vitamin B_{12} with either the particulate fractions or more especially with the *p*H 5 precipitate that contains the amino-acid activating enzymes. This observation was further confirmed by the finding by direct microbiological assay that only 10 per cent of the total natural vitamin B_{12} content of both deficient and normal livers was present in the *p*H 5 fraction. Even though the *p*H 5 fraction from deficient liver contained only one-tenth of the vitamin B_{12} present in the normal *p*H 5 fraction, the rate of amino-acid activation measured by the hydroxamate test or by incorporation of labelled amino-acid into soluble cell-sap nucleic acid was twice as great as for the normal preparations. The total protein and nucleic acid concentration of the 'deficient' and 'normal' *p*H 5 enzymes were the same. Although the rate of activation appeared greater in deficient livers, the incorporation into microsomal protein was generally the same or lower than into the normal liver fractions. With the adenosine triphosphate – phosphate (^{32}P) exchange as a measure of amino-acid activation, the results are more difficult to interpret, since we did not demonstrate a requirement for amino-acid in our system. Whatever process this exchange is measuring, there was no difference between the normal and deficient *p*H 5 enzymes, and vitamin B_{12} did not affect the exchange. However, the exchange was 35 per cent inhibited by a high concentration of the anilide of vitamin B_{12}, in confirmation of the observation of Wagle *et al.*[2].

Using the more complex fractions rich in microsomes to measure all the steps concerned in the incorporation of amino-acids into protein, we observed in two out of six experiments that the deficient preparations incorporated less carbon-14 amino-acids than the normal. In only one experiment of the six with fractions rich in microsomes was there any indication of an effect of added vitamin B_{12}. Vitamin B_{12} was tested as its cyano-, hydroxo-, and peptide form, and was usually without effect on the incorporation of carbon-14 activity into protein. These results agree with those of Arnstein and Simkin (see following communication), who used vitamin B_{12}-deficient and normal rat-liver preparations rich in microsomes. The anilide of vitamin B_{12} was used at high concentration in two experiments, but there was no depression of incorporation.

Experiments with chick liver minces showed that incorporation of carbon-14 labelled amino-acids into these whole-cell preparations was always less in the minces of vitamin B_{12}-deficient liver. It appeared that a small and erratic effect was obtained in some experiments on the *in vitro* addition of vitamin B_{12}. In similar experiments in which carbon-14 amino-acids were given intravenously into live vitamin B_{12}-deficient chicks and also into deficient chicks that had been given large doses of vitamin B_{12} on two successive days before the experiment, we could find no difference in incorporation into liver or heart muscle proteins. These *in vitro* experiments varied in time from 30 min. to 5 hr. (Coates, M. E., and Holdsworth, E. S., unpublished work).

Since we have not been able to find a direct role of vitamin B_{12} in the activation of amino-acid or in the incorporation into fractions rich in microsomes, it seems probable that the differences in levels of incorporation occasionally observed between deficient and normal microsome-rich preparations, and usually observed in the mince preparations, may reflect an indirect role of vitamin B_{12}.

Vitamin B_{12} and Biosynthesis in Rat Liver

By Dr. H. R. V. ARNSTEIN and Dr. J. L. SIMKIN*

National Institute for Medical Research, Mill Hill, N.W.7

THE nutritional importance of vitamin B_{12} for a wide variety of organisms, including mammals, birds, and micro-organisms, is well established. The underlying biochemical functions of the vitamin are, however, still unknown, although several different mechanisms have been suggested (for a recent review see ref. 1). An attractive suggestion, which could explain the diversity of the observed metabolic disturbances in deficient organisms, is the direct participation of vitamin B_{12} in protein biosynthesis and hence in enzyme formation[2,3]. The experimental basis for such a function is the decreased incorporation of labelled serine and glucose into the liver protein of vitamin B_{12}-deficient pigs and rats compared with that found in control animals *in vivo*[2],

* Present address: Department of Biological Chemistry, University of Aberdeen.

and the reduced labelling of microsome protein of both liver and spleen in a cell-free system[3]. Moreover, the addition of vitamin B_{12} *in vitro* to such a cell-free system from deficient rats has been reported to stimulate the incorporation of labelled methionine, alanine or phenylalanine into protein and thus to be effective in partially restoring protein synthesis to normal levels[3]. This effect of vitamin B_{12} has been ascribed to a function in the carboxyl-activation of amino-acids[4].

Other experimental evidence, however, appears to be in conflict with the foregoing results on the effect of vitamin B_{12} on protein synthesis in the intact rat. Thus, in the rat the incorporation of carbon-14-labelled methionine[5], serine[6], glycine[6] and histidine[7] into protein *in vivo* was not markedly decreased by vitamin B_{12} deficiency. In view of this discrepancy, the present experiments were undertaken in order to investigate further the suggested relationship of vitamin B_{12} to protein synthesis.

Vitamin B_{12}-deficient albino rats were obtained by breeding from depleted mothers which had also been fed on the vitamin B_{12}-deficient diet during pregnancy. The diet[8] had the following composition (gm./100 gm.): soya protein (α-protein, Glidden Co., Chicago, Illinois), 35; lactose, 17; glucose, 30; semi-hardened arachis oil (m.p. 33–35°; British Oil and Cake Mills, Erith), 12; salts (Glaxo mixture No. *DL*6), 5; vitaminized arachis oil[9], 2; and choline chloride, 0·3. Control animals were given vitamin B_{12} (cyanocobalamin) orally soon after weaning in doses equivalent to 5 μgm./rat/day (Table 1). With this diet, differences in body-weight between deficient and control rats usually became quite marked after 4–6 weeks. All livers used in the present experiments were checked for vitamin B_{12} depletion by microbiological assay with *Ochromonas malhamensis* essentially as described by Ford[10]. The average vitamin B_{12} content of deficient livers was 25 mμgm./gm. fresh weight, while livers of control rats contained about 160 mμgm./gm. (Table 1).

Minces were prepared by forcing liver through a metal screen with holes of 1 mm. diameter. Samples (0·5 gm.) from non-fasted deficient and control rats were incubated for 1·5 and 3 hr. under 95 per cent oxygen – 5 per cent carbon dioxide in 10 ml. of bicarbonate medium[11] with or without glucose (10·8 mgm.) and either uniformly labelled L-[^{14}C]valine (0·2 or 0·4 μc.; specific radioactivity, 53 μc./mgm.) or L-[^{14}C]phenylalanine (1 μc.; specific radioactivity, 70 μc./mgm.). After incubation, the flasks were cooled in ice, the medium was decanted and filtered through cotton wool, and the mince was washed twice with 2·5 ml. of 0·56 per cent sodium chloride. An equal volume of 10 per cent trichloracetic acid was added to the combined medium and washings to precipitate the protein (medium protein). The washed mince was suspended in 10 ml. of 0·56 per cent sodium chloride and disintegrated in a Potter–Elvehjem homogenizer with a 'Teflon' pestle. The suspension was centrifuged at approximately 700g for 10 min., the sediment was washed with 5 ml. of 0·56 per cent sodium chloride and centrifuged again. The 'soluble cell protein fraction' was precipitated from the original supernatant and washings by adding 10 per cent trichloracetic acid (15 ml.). The 'insoluble cell protein fraction' was obtained by adding 15 ml. of 10 per cent trichloracetic acid to the washed sediment. Each protein fraction was purified by dissolving in *N* sodium hydroxide, adding 10 mgm. of the appropriate unlabelled amino-acid, reprecipitating with 10 per cent trichloracetic acid and removing nucleic acid and lipid as previously described[12].

Table 2 shows that all protein fractions from minces of deficient rats had a lower specific radioactivity than those of controls, the greatest difference being found in the protein of the incubation medium. Addition of vitamin B_{12} *in vitro* increased the radioactivity of the protein only very slightly, however, the increase being usually less than 10 per cent. Since the uptake of vitamin B_{12} by rat liver slices is known to be rapid[13], absence of any marked stimulation of protein synthesis after incubation for 3 hr. would appear to exclude any direct effect of vitamin B_{12} on protein synthesis by intact liver cells.

Cell-free preparations were obtained by homogenizing rat liver in 0·25 *M* sucrose and separating the

Table 2. PROTEIN BIOSYNTHESIS BY LIVER MINCE FROM VITAMIN B_{12}-DEFICIENT AND CONTROL RATS

All results are calculated on the basis of 1 μc. of carbon-14 amino-acid added per flask. Except for experiment No. 2, results are means of duplicate flasks; individual values differed from the mean by less than 10 per cent in nearly all cases. In experiments Nos. 1 and 2, glucose (10·8 mgm./flask) was added to the medium

Exp. No.	Animal	Radioactive amino-acid added	Cyanocobalamin (10 μgm./flask)	Specific radioactivity of protein (mμc./gm.) after incubation for 1·5 hr. and 3 hr.					
				Protein from medium		'Soluble' cell protein		'Insoluble' cell protein	
				1·5 hr.	3 hr.	1·5 hr.	3 hr.	1·5 hr.	3 hr.
1	Deficient	Valine	–	54	200	435	860	198	352
			+	66	221	414	907	131	337
2	Control	Valine	–	—	665	—	1,139	—	650
			+	—	631	—	1,170	—	650
3	Deficient	Phenylalanine	–	97	350	1,289	2,021	465	854
			+	99	429	1,316	2,275	485	939
4	Control	Phenylalanine	–	159	604	1,685	2,585	664	1,075

microsome – cell sap fraction[14]. Samples of that fraction (2·5 ml.) were incubated at 37° under 95 per cent nitrogen – 5 per cent carbon dioxide with 3-phosphoglycerate as adenosine triphosphate generator and other additions as described elsewhere[15], the total volume being scaled down to 3·6 ml. Each flask contained 2 μc. of L-[^{14}C]phenylalanine (specific radioactivity 70 μc./mgm.). At the end of the incubation period, 2·5 vol. of cold 0·25 *M* sucrose containing unlabelled phenylalanine (1 mgm./ml.) were added and the mixture was centrifuged[15]. Protein was isolated from the microsome and supernatant (cell-sap) fractions[15] and purified as described above.

Fig. 1 shows that the cell-free system from vitamin B_{12}-deficient rats which had been fasted overnight incorporated somewhat less radioactivity into the protein of the microsome and cell-sap fractions than a similar preparation from the control animals. *In vitro* addition of cyanocobalamin (final concentration, 28 mμgm./ml.) had, however, no effect either on the rate of incorporation of phenylalanine into protein or on the final level of labelling. In another experiment with non-fasted rats (Table 3) a higher level of cyanocobalamin (140 mμgm./ml.) was equally ineffective in stimulating incorporation of phenylalanine, either alone or when added together with glutathione ($2·5 \times 10^{-3}$ *M*). Glutathione itself stimulated incorporation (cf. ref. 16), but the effect was relatively small. In a similar experiment with fasted rats which had been fed on a soya flour diet[10] instead of on the α-protein diet, the incorporation of a mixture of labelled amino-acids from hydrolysed [^{14}C]*Chlorella* protein into microsome protein was studied. The growth of deficient rats was retarded, but their livers were not as markedly depleted as those in the experiments in Table 1. Deficient animals had body-weights of 87, 95 and 105 gm. and a mean level of vitamin B_{12} in the liver of 98 mμgm./gm.; the corresponding values for control rats were 122, 122, 119 gm., and 160 mμgm./gm. Incubation was carried out under either 95 per cent nitrogen – 5 per cent carbon dioxide (for 10 min.) or 95 per cent oxygen – 5 per cent carbon dioxide (for 10 and 20 min.) and cyanocobalamin was added at 100 mμgm./ml. There was no significant difference in the radioactivity of the microsome protein of the preparations from the deficient and control animals. The radioactivity of the protein of the deficient cell-free system was increased by the addition of vitamin B_{12} by less than 15 per cent.

* Flask kept at 0° C.

The experiments with liver minces indicate that the incorporation of amino-acids into protein was less in livers of vitamin B_{12}-deficient rats than in those of control animals. Factors such as the size of the free amino-acid pool can, however, influence the rate of incorporation of labelled amino-acids into protein. The greatest difference was found in protein of the medium, which would be compatible with a decrease in protein secretion rather than in protein synthesis in vitamin B_{12} deficiency. There is, however, no indication that addition of the vitamin stimulates incorporation appreciably. Moreover, the experiments with cell-free systems failed to confirm the reported stimulation of protein synthesis by addition of vitamin B_{12} *in vitro*[3].

While our results do not exclude the possibility that vitamin B_{12} deficiency may result in decreased protein synthesis, they suggest that such an effect is secondary to some other biochemical function of the vitamin.

Two Atmospheric Effects in the Orbital Acceleration of Artificial Satellites

As I first pointed out[1], the orbital acceleration of artificial Earth satellites shows fluctuations which cannot be explained on gravitational grounds. In satellite 1957 β 1, these oscillations were rather irregular, although cycles of 19 and 37 days could be discerned[2,3]. According to E. C. Cornford[4], a periodicity of about 25 days was indicated, and this gave rise to speculations about possible tidal effects from the Moon. The same hypothesis was tentatively advanced by D. G. King-Hele[5] to explain oscillations with a period of 27 days in satellite 1958 δ 1. Earlier[3], in collaboration with R. E. Briggs, I had found oscillations with a period of about 30 days in satellite 1958 β 2, but had rejected the tidal hypothesis in view of the many observed irregularities and also because lunar tides should result in oscillations with about half the observed period. It was suggested, rather, that the rotation of the Sun, which has a synodic period of 27 days, could be responsible for changes in upper-atmosphere densities through variable radiation.

The oscillations in the orbital acceleration of 1958 δ 1 were quite regular, much more so than in 1957 β 1. Their period, as derived from 5 cycles, was 29 days, and their semi-amplitude was about 10 per cent of the mean acceleration (that is, the amplitude of the waves increased as the acceleration increased with the spiralling in of the satellite). The most remarkable feature of these oscillations, however, was that they were in phase with those of 1958 β 2, as can be seen from Fig. 1. Accurate acceleration data are not available, at present, for satellites 1958 α and 1958 ε, but a qualitative inspection of the available material (Whitney, C. A., private communication) has revealed that their accelerations, too, oscillated in phase with those of 1958 β 2 and 1958 δ 1. Moreover, accelerations obtained by Siry[6] and Whitney[7] for satellite 1958 γ give a maximum at about April 7 and a minimum near April 22, in close agreement with a maximum and a minimum on the curve for 1958 β 2. It appears rather evident that we are dealing with a global effect—a rhythmic pulsation of the atmosphere as a whole. Since the relative amplitude of the oscillations is much greater for the high-orbiting satellite 1958 β 2 than for the other, lower, satellites, it appears that the amplitude of the atmospheric variations increases with height.

It must be admitted that the regularity of the fluctuations in 1958 δ 1 is a little embarrassing for the solar-radiation hypothesis. Also, the period cannot be brought down to 27 days, although a period of 28 days fits the observations well enough (high latitude plages on the Sun could be responsible for a somewhat longer period since the rotation of the sun becomes slower at higher latitudes). A third difficulty consists in the fact that a 27-day periodicity in geomagnetic and ionospheric phenomena often makes its appearance in times of sunspot minima, but generally not in times of maxima—and now we are near a high maximum. In spite of these difficulties, the solar-radiation hypothesis still appears to me, in default of anything better, as the only plausible solution in sight.

Another effect, which is definitely tied to solar radiation, can be detected in satellites 1957 β 1, 1958 β 2, and also in 1958 δ 1. This is a variation of the orbital acceleration with the angular distance ψ of the perigee from the sub-solar point. The acceleration is greater when ψ is smaller, and the relation between the two variables is quite smooth. In particular, there is no discontinuity at the time when the perigee passes from night into daylight or

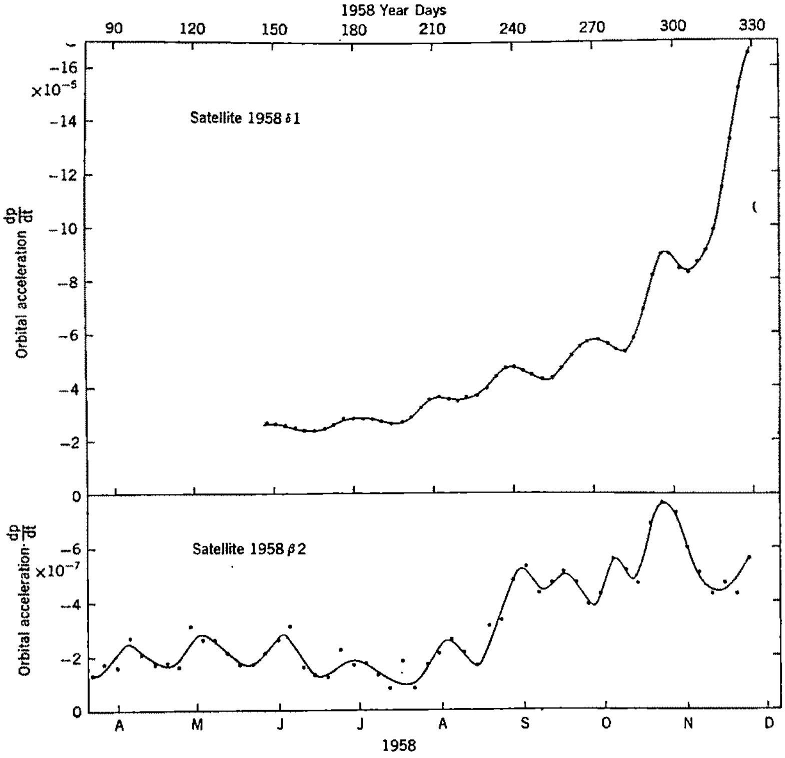

Fig. 1. Comparison of the orbital accelerations of satellites 1958 δ 1 and 1958 β 2 to show the in-phase fluctuations

vice versa, and the relation is quite discernible even in 1958 β 2, for which ψ always varied between 0° and 90° (that is, its perigee was always in the bright hemisphere). There are two possible explanations for this phenomenon. First, it could be due to variable charged drag[8] in an atmosphere in which the ionization decreases with increasing distance from the subsolar point. In this mechanism the satellite acquires a negative charge which will depend on the degree of ionization of the atmosphere, and there will be a supplementary drag caused by the positive ions it attracts from the sides. The second possibility is a real difference in density of the upper atmosphere between the bright and the dark hemispheres of the Earth. Fig. 2 illustrates the effect for satellite 1957 β 1.

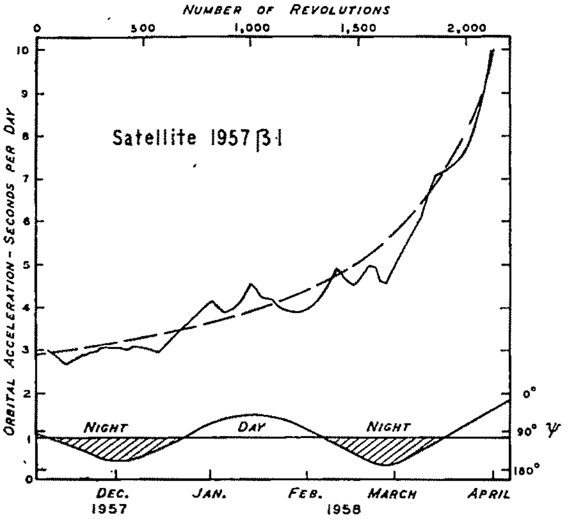

Fig. 2. Orbital accelerations of satellite 1957 β 1 compared with the geocentric angular distance ψ between the Sun and the perigee of the orbit of the satellite

Note added in proof, Jan. 14. In a communication dated Dec. 18, 1958, W. Priester, Universitätssternwarte, Bonn, finds a remarkable similarity between my acceleration curve of 1957 β 1 and the curve of the 20-cm. solar radiation in the interval Nov. 11, 1957–Feb. 10, 1958. Following this hint, I have compared the satellite data with the 10·7-cm. solar radiation data published by the National Research Council, Ottawa, during the period November 1957–December 1958. The correspondence is little short of perfect; there is a suggestion of a 2-day lag in the atmospheric (satellite) curve.

Irregularities in the Density of the Upper Atmosphere : Results from Satellites

WHEN an Earth satellite encounters air drag its orbit contracts and its period of revolution T decreases. For most of the satellites so far launched the rate of decrease of T has been irregular, thus implying irregularities in drag, which could be caused by changes in either the effective atmospheric density near perigee or the effective cross-sectional area S of the satellite perpendicular to the direction of motion. If, like most of those so far launched, the satellite does not point in a specific direction but rotates, S is to be taken as the mean cross-section during one complete rotation. The mean cross-section should remain constant as long as the mode of rotation of the satellite is unchanged, though it would not be constant if, for example, tumbling end-over-end changed to spinning like an aeroplane propeller. A clue to the mode of rotation is provided by the fluctuation in brightness of a satellite; if this remains almost the same for many months it is unlikely that the mode of rotation has changed appreciably.

For the rocket of *Sputnik* 3 (1958 δ 1), the rate of decrease of period was particularly erratic[1], but the brightness fluctuated regularly with a period which increased slowly from 8·5 sec. in July to 9·5 sec. in November. This strongly suggests that the mean cross-section did not vary significantly and that irregularities in the rate of decrease of period can be ascribed to variations in atmospheric density. Similar conclusions apply[2] to *Sputnik* 2 (1957 β). For both these satellites the perigee height decreased from 226 km. initially to about 180 km. 10 days before the end of the satellite's life, and any conclusions about air density relate to this height band.

The Royal Aircraft Establishment provided a prediction service for *Sputnik* 3 rocket, and more than 600 observations were received. A preliminary analysis of these has now been made, and the rate of change of nodal period has been calculated at intervals of 3 or 4 days. The results are shown in Fig. 1, in which the great majority of the observed values plotted are believed to be in error by less than 0·1 sec./day. For comparison, a theoretical curve, calculated on the assumption that density is constant from day to day, is also shown in Fig. 1. This curve is derived from the simplest theory, which gives :

$$\frac{dT}{dt} = -\frac{3e_0T_0}{4t_L\sqrt{1 - t/t_L}}$$

where t is time after launch, t_L is the total lifetime, e_0 the initial eccentricity, and T_0 the initial period. In assessing the irregularities in dT/dt, no advantage is gained by using a subtler theory.

The main feature which stands out in Fig. 1, and even more in Fig. 2, where the observed values have been divided by the theoretical, is an oscillation with a period of about 28 days. This oscillation seems more likely to be linked with solar disturbances than with lunar tides in the atmosphere, because the Moon completed one revolution, relative to the perigee of the satellite's orbit, in about 22 days; whereas the Sun rotates, relative to the Earth, once every 27·3 days. The rather sharp onset of the increases in drag, together with the fact that their periodicity agrees better with the solar period than the lunar one,

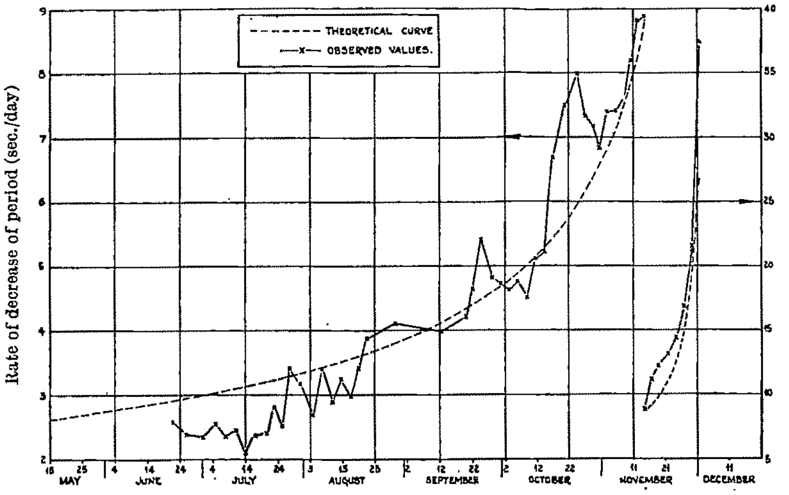

Fig. 1. Rate of change of period for *Sputnik* 3 rocket (1958 δ1)

suggests that the changes in air density are associated with the streams of particles which are projected radially from the Sun and sweep across the Earth at intervals of 27–28 days, giving rise to well-known periodicities in geomagnetic activity[3], cosmic rays and the aurora[4].

Other possible causes of irregularities in air density do not fit in well with the 28-day oscillation. If the movement of perigee from darkness into daylight is an important factor, as suggested by Sedov[5] and Groves[6], there would be an oscillation with a period near 3 months. Figs. 1 and 2 indicate that, though the change in density from day to night may well have some influence, it is not the dominant effect. Another possible source of irregularity is the variation of density with latitude[7]. During the life-time of *Sputnik* 3 rocket, the perigee moved from latitude 50° N. to latitude 20° S. The 28-day periodicity in the values of dT/dt implies maxima of density at intervals of about 10° in latitude. It seems unlikely that the variation of density with latitude should show an oscillatory pattern of this kind, though it cannot be entirely ruled out. It would, however, be surprising to find no variation of density with latitude, and if the irregularities are ignored Fig. 2 might seem to indicate that density increases by about 50 per cent between latitude 40° N. and the equator. The true increase in density is likely to be appreciably less than this, however, since part of the increase is accounted for by the Earth's oblateness, which reduces the height of perigee above the Earth's surface. For the *Sputniks* so far launched, with inclinations near 65°, perigee has taken about a year to make a half-circuit of the Earth, and the increase in the mean value of the quantity plotted in Fig. 2 between latitude 40° N. and the equator can be looked upon as one half-period of the oscillation in dT/dt produced by the periodic change in the latitude of perigee, though some seasonal effect may also be present.

Do the results from other satellites confirm the suggestion that solar disturbances are responsible for the irregularities in air density? For *Sputnik* 1 and its rocket (1957 α 2 and 1) the data available to us are not precise enough for any conclusions to be drawn. With *Sputnik* 2 (1957 β) a somewhat similar periodicity was discernible[2], with maxima of drag occurring about January 20, February 15 and March 15, 1958; and Nonweiler[8] found a significant correlation with solar flares. For *Sputnik* 3 (1958 δ 2), increases in drag occurred about 80, 110 and 140 days after launch, but accurate optical observations have been rather infrequent and the variations have not been accurately determined. For the United States satellite *Explorer* 1 (1958 α), and for *Explorer* 3 (1958 γ), except during its last weeks, perigee crossed the equator at intervals of between 24 and 30 days; the oscillations in dT/dt produced by the periodic change in perigee latitude therefore had a period between 24 and 30 days[9], and, in the present state of knowledge, cannot be reliably distinguished from solar influences of similar period. With *Vanguard* 1 (1958 β 2) somewhat irregular oscillations with [a period near 30 days have been observed and tentatively ascribed[10] to solar influences. Our information on *Explorer* 4 (1958 ε) is limited, but its drag, like that of *Sputnik* 3 rocket (Fig. 2), increased sharply about August 22, 1958, and decreased about September 8.

Thus, it appears that irregularities in air density, especially at heights between 180 and 225 km., tend to recur at intervals of about 28 days, and that this periodicity may well be related to solar disturbances. Variations in density from day to night and with latitude appear to be rather less important. These conclusions must, however, at present be regarded

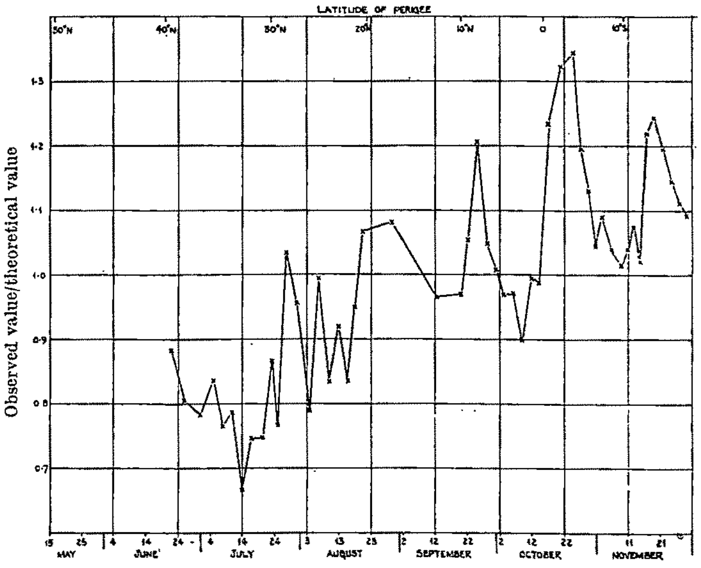

Fig. 2. Rate of change of period of *Sputnik* 3 rocket (1958 δ1). Ratio of observed values to theoretical

as somewhat speculative; there is need for data from further satellites and for a more thorough analysis of existing results.

Natural Magnetic Moments of Two Chondritic Meteorites

Most of the secondary or chondritic meteorites are composed of irregular grains of silicate, sulphide, phosphide, oxide and metal phases. They are generally thought to be fragments of secondary meteorite bodies which were themselves accumulations of debris from disrupted primary bodies. The process of compaction of the secondary bodies does not appear to have been accompanied by sufficient heating to have melted any of the constituent phases[1,2], which leads to the general conclusion that these secondary bodies did not have fluid, conducting cores capable of producing terrestrial-type magnetic fields, as is possible in the primary meteorite bodies[3]. This implies that alignment of magnetic particles or induction of thermo-remanent or chemical magnetization is unlikely to have occurred in the secondary bodies and therefore that the chondritic meteorites would not be expected to have magnetic moments other than those acquired on the Earth.

We have found substantial natural magnetic moments in the three chondrites which have been examined and have used two of them (Homestead and Mount Browne) in thermal demagnetization experiments to obtain information about the origin of their moments. The Homestead meteorite is a polymict, brecciated grey bronzite-chondrite[4], and a preliminary modal analysis indicates the magnetic constituents to be 1 per cent magnetite and 9 per cent metal by weight. The Mount Browne chondrite is very similar but with a higher proportion of metal, 19–34 per cent[5]. Samples of about 35 gm. were taken from parts of each of these meteorites, more than 3 cm. below the fused crusts, so that the samples could not have been heated above about 100° C. during ablation in the Earth's atmosphere[6]. Both meteorites were observed falls and no obvious oxidation of the metal phases has occurred in the samples examined.

The magnetic moments were measured in a spinner-magnetometer[7] simultaneously with heating to 800° C. in a nitrogen atmosphere. Each of the thermal demagnetization curves revealed three constituent magnetic moments not obviously related in direction; the differences in their directions were of considerable use in distinguishing them.

(1) The low-temperature moment disappeared at 100° C. in Homestead and 90° C. in Mount Browne. This moment was probably acquired after arrival on the Earth, apparently having been induced by a field comparable with that of the Earth in conjunction with possible heating to a temperature not greater than 100° C.

(2) The medium-temperature component behaved in much the same way as the natural moments of magnetically stable igneous rocks, several of which have also been examined with the magnetometer. This component is largely associated with the magnetite grains, although it finally disappeared at 630° C., some 50° C. higher than the Curie point of magnetite, indicating incomplete distinction from (3).

(3) The high-temperature component had a direction clearly different from (2) and disappeared at 775° C., approximately the transformation temperature of the metal phase (Parry, L. G., private communication).

The difference in character between components (2) and (3) was clarified by repeating the demagnetization measurements after the meteorite samples had been exposed isothermally to a field of 15,000 oersteds and also after cooling from 850° C. in a steady field of 10 oersteds. In each case component (3) appeared in the same direction as in the natural state, but (1) and (2) (no longer distinguishable) were in the direction of the inducing field, at a wide angle from (3). This unexpected and anomalous behaviour of component (3) is difficult to explain. It may be due to strongly anisotropic metallic grains from which a plane of layering might be inferred.

For the present purpose component (2) is the most useful one. For the Mount Browne sample this component has been vectorially subtracted from component (3) and displayed as a function of temperature in Fig. 1 for the three cases of natural

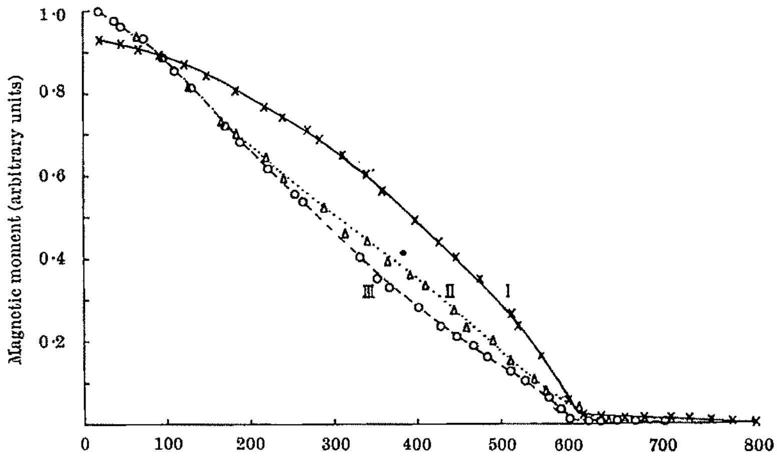

Fig. 1. Thermal demagnetization of Mount Browne chondrite. I, Artificial thermo-remanent moment; II, medium-temperature component of natural moment; III, isothermally induced moment. Curves normalized to coincide at 90° C.

moment (curve II), moment induced isothermally by 15,000 oersteds (curve III), and thermally by cooling in 10 oersteds (curve I). The curves have been normalized to coincide at 90° C.

Since curve III represents thermal demagnetization after saturation, moments induced isothermally by smaller fields would be less resistant to demagnetization and give curves lying below this. The fact that curve II lies above it suggests that the natural moment was induced either thermally or during the course of chemical or phase changes or grain growths, to which the general term chemical magnetization applies. Agreement with curve I, representing the artificial thermoremanent moment, is not very close, so that the natural moment may be due to chemical magnetization; it is known that the latter resists demagnetization more strongly than isothermally induced magnetism but less strongly than thermally induced magnetism[8].

Since it is evident that the chondrites have not been substantially heated or chemically changed after their arrival on the Earth, and that they have thermo-remanent or chemical magnetization, their natural moments must have been induced by extra-terrestrial fields. Also, components (1) and (2) of the natural moments are different, not by virtue of different magnetic constituents in the meteorites but by their having been induced in different fields, (1) being superimposed after (2) was established. Component (1) is evidently terrestrial in origin and component (2) apparently extra-terrestial.

It seems likely that the required extra-terrestrial fields originated in the secondary meteorite bodies themselves. Either these bodies had fluid conducting cores, contrary to the usual conception of them, or else fluid cores are not necessary for the generation of magnetic fields of terrestrial type. A choice between these alternatives may be made when we know whether the Moon has a magnetic field, since it is highly unlikely that the Moon has a fluid conducting core.

PHYSICS

Correlation of Sedimentation-Rates by Dimensionless Groups

DIMENSIONLESS groups are extensively used for correlating data involving fluid flow. Some of the best-known applications include flow through pipes[1-3], movement of bodies through fluids[2-5] and flow of fluids through porous media[5,6]. It is usual to plot a friction factor, ψ, against Reynolds number or a modification of it, B (say), and the relationship thus obtained is of the form:

$$\psi = \frac{K}{B^N} \qquad (1)$$

in which N and K are parameters.

The initial stages in the sedimentation of a suspension[5,7] are frequently characterized by a constant settling-rate, and it has been found that a good description of experimental results[8] is provided by:

$$U = U_0 \varepsilon^n \qquad (2)$$

in which U is settling-rate of the suspension; U_0 is settling-rate of the solids at infinite dilution; ε is porosity of suspension, that is, volume fluid per unit volume suspension ($\varepsilon = 1 - C$, where C is volume concentration of solids). Some approximate values for the parameter, n, are 4·7–5 for streamline flow for spheres, 2·4 for turbulent flow for spheres and 7–10 for rough particles.

If plug flow is assumed to account for the constant settling-rate, by forming force balance equations and using dimensionless groups, it can be shown that:

$$\psi = \frac{\varepsilon^2}{U^2 S}\,\frac{\sigma - \rho}{\rho}\,g \qquad (3)$$

$$B = \frac{U\rho}{(1 - \varepsilon)S\eta} \qquad (4)$$

in which S is specific surface area of solid per unit volume; η is absolute viscosity of fluid phase; σ, ρ are density of solid and fluid phases respectively.

The remaining symbols have their usual meaning and, in equation 4, B is called the Blake or modified Reynolds number. The theoretical model used is perhaps the simplest description of sedimentation, though two refinements were introduced into the derivation of equations 3 and 4. These were: (*a*) the velocity of flow in the interstices of the suspension (U/ε) was used instead of the sedimentation-rate, and (*b*) in place of the usual mean particle diameter, equivalent hydraulic radius of the bed was employed. Consequently, equations 3 and 4 are similar to (and could be considered as extensions of) the Blake–Carman correlation[5,6] for the flow of fluids through porous media. In this, $N = 1$ for laminar flow and equation 1 reduces to Kozeny's equation[5,6], in which $K \simeq 5$. For spheres the equation holds over the porosity-range of approximately 0·4–0·55.

If the relationship between equations 1, 2, 3 and 4 is examined, it can be shown that when $n = 5$ (the approximate value for streamline flow for spheres) and as ε decreases from 0·8 to 0·7, then N increases from 0·9 to 1·1, while K remains almost constant at 4·8. These values for N and K compare favourably with the constants of Kozeny's equation, which is of interest in view of the lower range of porosity for which this equation holds.

Whitmore[9] has reported measurements of sedimentation-rates with two sets of spherical particles. He found $n \simeq 4 \cdot 8$, and though the results are somewhat limited, correlating them with equations 3 and 4 shows that when $\varepsilon = 0 \cdot 75$ and $0 \cdot 80$ then $N = 1$ and $K = 5 \cdot 5$. The value of N remained constant at all porosities, but K increased with porosity, ranging from 6 when $\varepsilon = 0 \cdot 85$ to $13 \cdot 5$ when $\varepsilon = 0 \cdot 95$. This trend may be attributed to departure from plug-flow conditions, which will tend to become more serious as porosity increases. Further work on the sedimentation-rate of spherical particles has been reported by Richardson and Zaki[10], who found $n \simeq 4 \cdot 7$–5. Consequently, a correlation by equations 3 and 4 could be expected.

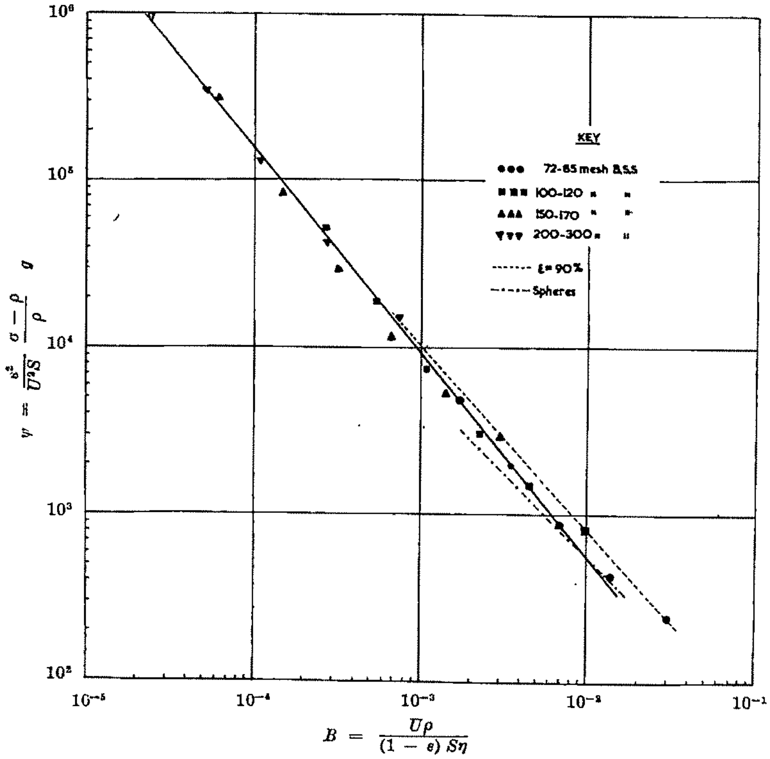

Fig. 1. Sedimentation of rough particles; relation between friction factor and Blake number

Particle shapes other than spherical introduce complications, and shape factors are generally employed to take account of this. However, results obtained by Whitmore[8] for four graded sizes of rough methyl methacrylate powders and correlated according to equations 3 and 4 are shown in Fig. 1. Values of surface area were calculated from the mean particle diameter assuming spheres or cubes, and are probably somewhat smaller than the true values. Thus, if the shape factor is independent of particle size, the true correlation would differ from that shown in Fig. 1 in only one detail, namely, the slope and the relationship of the points to each other would remain unchanged but K would be diminished. In the correlation, $N \simeq 1 \cdot 2$, which is not unexpected because $n \simeq 7-9 \cdot 5$, as compared with $4 \cdot 8$ for spheres. The points representing low concentrations of solids again diverge from the general trend but not in such a pronounced manner as with spheres. This may be because rough particles interlock more readily than spheres and as a consequence conditions of plug-flow may still persist at reduced concentrations.

The scope of this method of representation is yet to be investigated, especially with regard to the shape and effective size of the particle. Two important cases are flocculation and the apparent diameter of rough particles carrying fluid on their surfaces. A further possible investigation, which might be of interest, follows from the similarity between the present and the Blake–Carman correlation which would enable the transition from fluid flow through porous media into sedimentation to be followed on a single diagram. This could be considered to be a function of increasing porosity.

It is believed that equations 3 and 4 have not been proposed before, which is somewhat surprising in view of the widespread application of other similar correlations. In connexion with this, Dr. J. F. Richardson (private communication) has pointed out that Minz[11] employed dimensionless groups for dealing with sedimentation-rates; Minz employed the Blake–Carman correlation directly and worked in the Blake number range 0·1–100, where transition from laminar to turbulent flow takes place. He found that when $B = 1$, $N = 0 \cdot 95$ and $\psi \simeq 5$. Consequently, $K \simeq 5$, which compares favourably with the results obtained here.

Finally, it is possible to raise objections to the use of dimensionless methods to describe flow through porous media, since the method is based upon an assumption of dynamic and hence geometrical similarity which cannot hold for a system of particles in which geometrical configuration is varied in order to obtain different porosities. Consequently, as Rose[12] points out, the results may be empirical, but "the method is an extremely powerful tool for preliminary examination of a very difficult problem".

I wish to thank Prof. J. T. Whetton for interest and encouragement, and my colleagues, Mr. H. G. Smith, Dr. A. Jowett and Dr. G. D. Lill, for useful discussion, and also Dr. R. L. Whitmore, of the University of Nottingham, and Dr. J. F. Richardson, of the Imperial College of Science and Technology, London, for their comments on an earlier draft of this communication.

Variations in the Value of Reynolds Number at the Transition from Streamline to Turbulent Flow

THE flow of nitrogen through a porous copper disk has been investigated experimentally at mean pressures of 2–80 atm., and the flow of carbon dioxide through the same disk has been investigated up to mean pressures of 50 atm., at room temperature. The difference in pressure across the disk was never

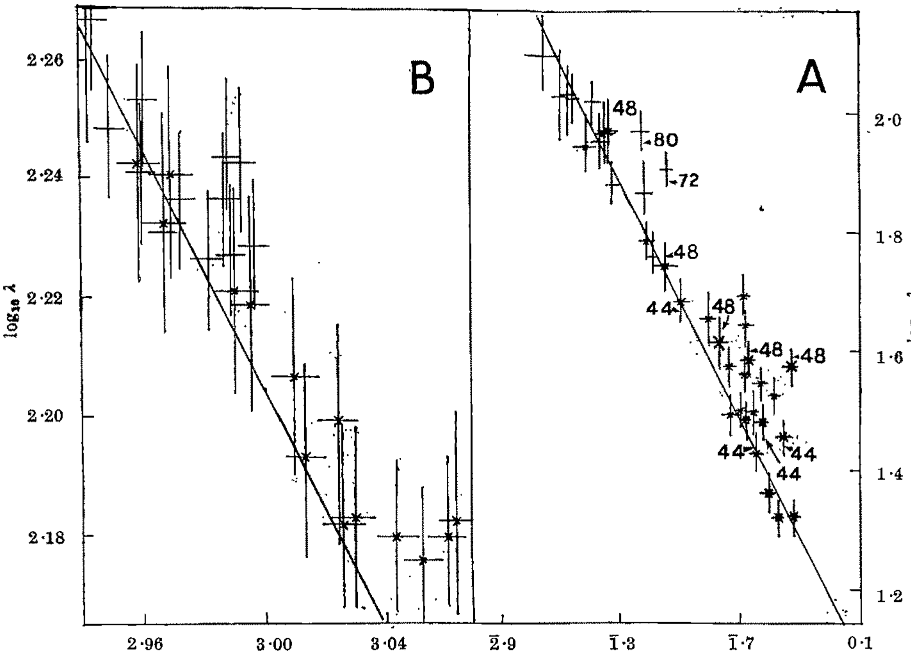

Fig. 1. Graph showing the variation of the friction factor, λ, with the Reynolds number, Re. *A*, For a porous copper disk mean pore radius about 10^{-4} cm. and thickness 0·005 cm.; *B*, for a copper tube about 1 m. long and 0·18 cm. dia. The lengths of the arms represent experimental errors. +, nitrogen; *, carbon dioxide. (Note: The scales are different in the two figures)

more than 0·6 atm. and was as small as 0·2 atm. in some experiments. As the mean pressure was increased from 2 atm. the flow through the disk remained streamline up to mean pressures of nitrogen of about 70 atm. and up to mean pressures of carbon dioxide of about 40 atm., the value of the pressure at which the flow departed from streamline flow being dependent on the pressure difference. Results showing the departure of the flow from streamline flow are given in Fig. 1*A*; some of the mean pressures are shown in Fig. 1 opposite the relevant points; but most pressures have been omitted so as not to confuse the diagram. The straight line represents streamline flow through the disk. Points lying off the straight line are usually attributed to the onset of turbulence; accepting this interpretation if R'_e be the value of the Reynolds number at which turbulence begins then it is apparent from Fig. 1 that (1) R'_e for nitrogen is different from that for carbon dioxide; (2) R'_e for carbon dioxide diminishes as the mean pressure increases.

When the results shown in Fig. 1*A* were first obtained, as an incidental part of a different research programme[1], the results were unusual; but corroborative evidence for variations in the value of Reynolds number at the onset of turbulence has been found since in Lindgren's work[2,3] and in our recent work. Lindgren worked with aqueous solutions of bentonite. He used birefringence to study flow patterns in the solutions as the solutions flowed through a cylindrical glass tube; in addition, he measured drop of pressure occurring in the flow. As the concentration of the bentonite solutions was altered variations were found in the values of Reynolds number at the onset of turbulence which could not be accounted for by changes in the variables occurring in Reynolds number, or by variations in such factors as entry length, which are known to alter the value of Reynolds number at the onset of turbulence.

In our recent work the flow of nitrogen and carbon dioxide at atmospheric pressure through a long copper tube was studied, the pressure difference being about 0·02 atm.; some results are shown in Fig. 1*B*. In Fig. 1*B* the maximum experimental errors are shown, and it is seen that the value of the Reynolds numbers for the onset of turbulence in nitrogen is certainly different from that for the onset of turbulence in carbon dioxide, although the difference is not nearly as marked as it is in the work with the porous copper disk.

In both the tube and the porous disk the values of the Reynolds number at the onset of turbulence are about those quoted for the critical Reynolds numbers for flow in tubes and porous media respectively. That a value for Reynolds number which is so near the value quoted for the critical Reynolds number should vary as the identity of the fluid is altered and also as the pressure is altered in a given fluid suggests a relevant dimension is omitted in the analysis; the temperature is a dimension which is omitted, and it may well be that energy transfer occurs in the gases at what appears to be the transition from streamline to turbulent flow in such a way that the flow is no longer isothermal. But additional experimental and theoretical evidence is required; the problem is: given a piece of apparatus, can the extent of the streamline flow of any compressible fluid in the apparatus be predicted precisely from a series of experiments showing the extent of the streamline flow with one fluid at one given mean pressure?

Effect of Humidity on the Breakdown of a I-cm. Homogeneous Field Spark Gap in Air

The effect of humidity on the breakdown voltage of a homogeneous field spark gap in air has been reported in a previous communication[1]. The increase in voltage with humidity agrees with the results of Ritz[2] and Köhrmann[3] for homogeneous fields, but it is greater than the figure of 0·13 per cent increase per mm. mercury of water found by Lewis[4] for a 0·4-cm.

Table 1. SUMMARY OF BREAKDOWN VOLTAGE MEASUREMENTS ON PLANE ELECTRODES

Author and date		Measured breakdown voltage of 1-cm. gap (kV.)	Conditions		Type of voltage	Breakdown voltage of 1-cm. gap corrected to dryness at 20° C. 760 mm.
Schumann	1922	31·7	Wet, humidity unknown	20° C.	a.c.	30·8*
Klemm	1923	31·4	About 40 per cent humidity (~ 6·9 gm./cu.m.)	20° C.	a.c.	30·5
Spath	1923	31·55	Wet, humidity unknown	20° C.	a.c.	30·6*
Holzer	1932	31·66	Between 30–80 per cent humidity (~ 5·2–13·8 gm./cu.m.)	20° C.	a.c.	30·9–30·4
Ritz	1932	31·35	Wet, humidity 10 mm. (~ 9·8 gm./cu.m.)	20° C.	a.c.	30·3†
Fisher	1947	30·1	Dry	22° C.	d.c.	30·3
Bruce	1947	30·3	Humidity unknown	20° C.	a.c.	29·7‡
Köhrmann	1956	30·1	Dry	20° C.	d.c.	30·1
Present	1958	—	Dry	20° C.	d.c.	29·9–30·3

* Voltage obtained assuming 40 per cent humidity, but it may be more than this, with the result that the voltage will be even lower From the relative humidity data for Jena (1923) prepared by the Meteorological Office this figure appears to be rather low and a better value may be of the order of 70 per cent humidity.

† This value is obtained from Ritz's work on the humidity correction and it agrees with our value.

‡ Assuming 4 mm. of water vapour.

gap between 2-cm. diam. spheres. It is important to know the actual breakdown voltage of a 1-cm. gap not only from the point of view of attempting to understand the mechanism of a spark but also from the more practical application in high-voltage engineering.

For the purpose of comparison a summary of breakdown voltage measurements for plane electrodes obtained by different workers is given in Table 1. The first column gives the author and date of the publication and the second column the observed breakdown voltage. The third column shows the humidity and temperature conditions of the air, while the fourth and fifth columns specify the type of voltage applied, a.c. or d.c., and the breakdown voltage corrected for humidity and a temperature of 20° C.

The differences between the measurements of column 2 made by the early German workers and the later values are almost ± 2·5 per cent about a mean, and it is difficult to account for these differences purely on grounds of errors in voltage measurements. It must be remembered, however, that little attention was paid to the effect of humidity on the breakdown value before the work of Ritz. Klemm[5] indicated that the humidity was about 40 per cent, Schumann[6] and Spath[7] did not consider it, and Holzer[8] mentioned that the humidity was between 30 and 80 per cent. By using our measured increase of voltage with humidity and assuming a figure of 40 per cent for Schumann and Spath, the corrected values are 30·8 kV. for the former and 30·6 kV. for the latter. Holzer's value for the breakdown voltage is reduced to 30·9 kV. for an assumed humidity of 30 per cent and 30·4 kV. for 80 per cent. Ritz's result is reduced to 30·3 kV. when corrected for 10 mm. of water vapour. Fisher's[9] value for the breakdown of a 1-cm. uniform field gap in dry air has also to be corrected for temperature since the measurements were normalized to 22° C.

The values of the breakdown voltage measured by us lie between 29·9 and 30·3 kV. in dry air at a pressure of 760 mm. mercury at 20° C. The low values in the region of 29·9 kV. were obtained with brass and aluminium alloy electrodes which had been freshly polished. These values, however, increased rapidly to about 30·1 kV. with a little sparking and may be attributed to the formation of oxide layers on the cathode. Another 'conditioning' effect which increased the minimum breakdown from 30·1 to 30·3 kV. was most likely due to changes in the gas, and is noticeable in the present work due to the fact that the electrodes were mounted in an enclosed chamber. The absolute accuracy of the present work is about ± 0·5 per cent and the more stable value of 30·3 kV. agrees reasonably well with the corrected values given in column 5 of the table. Examination of these corrected results shows that all the values lie within a range of approximately ± 1 per cent about a mean. Furthermore, if the results prior to 1932 are ignored, and the lower breakdown values coresponding to the higher humidity is taken for Holzer's results, then the differences are as low as ± 0·6 per cent. This is much smaller than is indicated by the uncorrected values given in column 2 and can almost be accounted for by experimental errors. These limits are based on the assumption that the figure of 30·3 kV. given by Bruce[10] is for dry air. This seems rather unlikely, and even if the humidity was only 4 mm. mercury, then Bruce's value will be reduced to 29·7 kV. for dry air, the lowest value in the table. However, this value does not differ significantly from the low values found in the present work using freshly polished electrodes.

CHEMISTRY

Stable Configuration of Methyl Groups in Dimethyl Ether

THE internal rotation of a methyl group about its symmetry axis, despite the presence of the group in a great variety of organic molecules, has attracted little attention, probably because experimental methods such as dipole moment measurement, etc., are not available for the elucidation of the problem. In the structural determination of molecules containing methyl groups, each group is often considered as a whole rather than as four separate atoms[1]. However, the determination is not complete, unless the

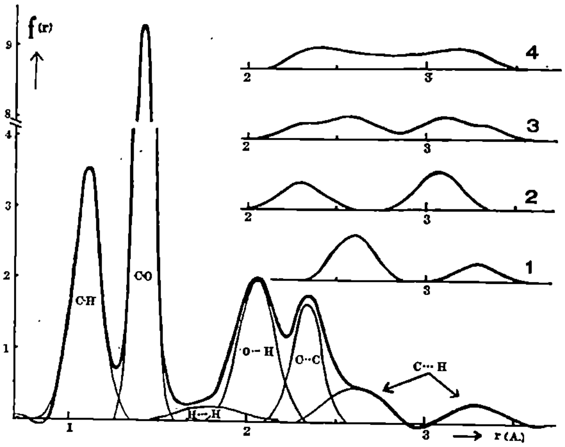

Fig. 1. Experimental radial distribution curve $f(r)$ and the theoretical contributions of C . . . H distances to it for various models

stable configuration of hydrogen atoms in molecules is taken into account. Recent advances in the experimental technique of electron diffraction by gas molecules have made it possible to determine the values of structural parameters with higher precision than formerly. For the present purpose, a dimethyl ether molecule is perhaps the simplest prototype amenable to the sector-microphotometer method in electron diffraction, because the molecule has non-bonded C . . . H distances which are sensitive to the rotation of methyl groups and contribute appreciably to the total scattered intensity.

The electron diffraction photographs were taken with an apparatus[2] having an r^3-sector and a beam trap. Two camera distances, of 12 cm. and 28 cm., were used, the s-region covering 2–12 and 5·5–30, respectively. The conversion of photographic density into total scattered intensity was made by Karle's method[3]. The molecular term of scattered intensity was evaluated by drawing a smooth background through the total intensity curve on the basis of the usual criteria[3], a correction being made for non-nuclear scatterings[4]. In computing the radial distribution curve shown in Fig. 1, theoretical intensity curves for $s < 2$ and $s > 30$ were joined on to the observed curve. No damping factor was used towards the last steps of successive approximations, because the intensity for $s > 30$ was dominated by contributions from bonded C—O distances which could be determined accurately.

The radial distribution curve has two prominent peaks corresponding to bonded C—O and C—H distances. They are isolated and give definite values, 1·416 ± 0·003 A. and 1·094 ± 0·006 A., for the respective atomic distances. Two mutually overlapping peaks can be assigned largely to non-bonded C . . . H distances and a non-bonded C . . . C distance, which leads to a value of 111·5° ± 1·5° for the angle COC. A hump at about 2·6 A. on the right-hand side of the C . . . C peak and a weak peak at 3·3 A. are due solely to contributions from non-bonded C . . . H distances, because the contributions from H . . . H distances between hydrogen atoms belonging to different methyl groups are negligibly small. This gives a clue to the elucidation of the position of the methyl groups relative to the framework. Theoretical curves were therefore calculated for four different models: (1) a model performing restricted rotation about a C_{2v} form as an equilibrium position, with two hydrogen atoms belonging to different methyl groups at the maximum distance apart; (2) the same as (1) except that the two hydrogen atoms are at the minimum distance apart; (3) a model having C_s symmetry, that is, a gear type having a plane of symmetry; and (4) a free-rotation model. These theoretical curves differ from one another to a considerable extent as shown in Fig. 1, and the comparison with the observed curve leads to an unequivocal conclusion that the agreement is best between the experimental curve and the theoretical curve for model 1. One might suspect that the experimental radial distribution curve will be affected by the selection of models, because the theoretical intensity curves were joined on to the observed intensity curve. Examination showed that the experimental radial distribution curve was almost independent of models, on the basis of which the theoretical intensity was calculated for the unobserved s-regions.

In order to confirm the result, theoretical intensity curves were computed for the above-mentioned models with their parameters varied over appropriate ranges and compared with the experimental intensity curve. It was found that the curve for model 1 gave the smallest average deviation of s/s_{exp}. A further check was made by examining the observed intensity at small angles by Morino and Kuchitsu's method[5] for the study of internal rotation. Only model 1 satisfied the required criterion. Hence it is concluded that the internal rotation in this molecule is not free, but that the molecule exerts restricted rotation about the stable configuration having C_{2v} symmetry. Details of this work have been submitted to the *Journal of Chemical Physics*.

Catalytic Action of Copper in the Alkaline Autoxidation of Cellulose at Low Alkali Concentration

Bell and Gibson[1] have suggested that the degradation suffered by cellulose in contact with rusting iron is the result of autoxidation catalysed by the iron itself under the alkaline conditions resulting from the process of corrosion. Very little information is available concerning the influence of metals in the autoxidation of cellulose at the low alkali concentrations likely to be involved in such a system. It may therefore be of some interest to describe the results of an investigation in which it was found that copper has apparently an unexpectedly high catalytic effect in the reaction of cellulose with oxygen at low alkalinities.

Small hanks of commercially bleached cotton yarn, soaked in 0·2 M copper sulphate solution, were

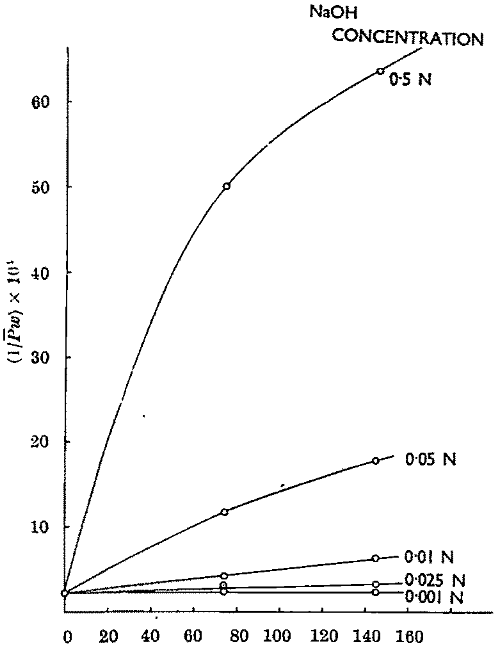

Fig. 1

immersed in sodium hydroxide solution to precipitate the copper, giving a deposit of about 2·5 per cent copper on the yarn. The hanks were then variously conditioned by three immersions of 15 min. each in one of a range of solutions of sodium hydroxide varying in concentration from 0·5 *N* to zero, thus giving a series of specimens containing differing small quantities of free alkali. The hanks were centrifuged, dried and stored in the dark in loosely capped bottles. In additional experiments with cotton containing 'B.D.H.9011' indicator, it was shown that on exposure to the atmosphere the free alkali was converted beyond the stage of carbonate in less than 1¼ hr. even with the highest alkali concentration used.

At intervals the weight–average degrees of polymerization ($\bar{P}w$) of the specimens impregnated with copper were obtained[2,3] from the viscosity in cuprammonium hydroxide solution. Fig. 1 shows the variation of reciprocal $\bar{P}w$ with time. Such a plot gives a direct measure of the reaction-rate provided that the ratio of $\bar{P}w$ to $\bar{P}n$ (the number-average degree of polymerization) remains constant, a condition known to obtain in the heterogeneous acid hydrolysis of cotton[4].

To a first approximation the rate of alkaline autoxidation of cellulose may be taken as proportional[5] to the concentration of sodium hydroxide below 5 *N*. It is accordingly possible to obtain from Davidson's work[6] an estimate of the rate at which alkali-impregnated cotton may be expected to autoxidize without added catalyst at low concentrations of alkali, in terms of the time required to reach a given extent of depolymerization. The rate of degradation observed with 0·05 *N* sodium hydroxide is then found to be greater than that calculated from Davidson's results by a factor of approximately 4 if absorption of carbon dioxide is not taken into account. Assuming conversion to carbonate, the calculated decrease in *p*H corresponds to an increase in catalytic factor to approximately 80, while the true value must be substantially higher than this in view of the inevitable absorption of carbon dioxide beyond the stage of carbonate. Other workers[6,7] concerned with alkali concentrations of 5 *N* or higher have found that less than a ten-fold increase in rate can be brought about by the addition of metals such as iron, cobalt, nickel, manganese or copper. This remarkable difference in catalytic behaviour cannot be accounted for with certainty on the basis of the results at present available. However, one possible explanation is that at high concentrations of alkali, as the concentration of catalyst is increased, the reaction-rate may become dependent on the availability of oxygen and thus eventually independent of the concentration of catalyst (such independence is in fact observed[6,7]). This limitation would be less likely to apply in the present system, where the rates of reaction are relatively low.

Electron Microscopy of Sodium Laurate

Although a number of papers have been devoted to the electron microscopy of soaps deposited from aqueous solution[1–4], none has reported a study at high resolution. It is the purpose of this communication to discuss some preliminary results of an investigation into the fine structure of sodium laurate using high-resolution electron microscopy and electron diffraction.

Sodium laurate was made from pure lauric acid. Samples for electron microscopy were prepared by allowing a drop of solution to dry down on a carbon-coated electron microscope grid. To minimize thermal damage in the electron beam the specimens were shadow-cast with gold–palladium alloy at an angle of $\tan^{-1}\frac{1}{2}$. Adjustment of the *p*H of the solution to 10·0 made no difference to the structure of the soap.

The form of the deposit varied with the concentration. From solution at low concentration (< 0·02 per cent) the soap crystallized into well-defined needles which at high magnification showed no characteristic substructure. As the concentration was increased beyond about 0·05 per cent a close network of ribbon-like fibres was formed (Fig. 1), the thickness of the ribbon being perpendicular to the substrate. This is in accordance with the findings of other workers. At high magnification these fibres appeared to consist of an array of cylinders or spheres approximately 30 A. in width arranged in lines along the fibre axis (Fig. 2); the periodicity across the fibre was 50–80 A. This regularity of fibre substructure was also shown by sodium laurate dispersed by mulling in *n*-butanol[2] and by carbon replicas of soap fibres dried down on mica. While it is likely that the contrast in the image is due directly to agglomerated particles of shadowing metal, the regularity in the structure indicates that agglomeration on to some unit within the fibre is occurring.

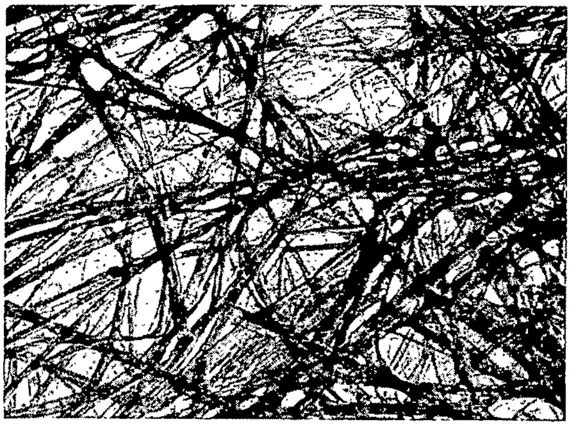

Fig. 1. Low-magnification micrograph of sodium laurate fibres grown from air-dried aqueous solution. (× c. 8,500)

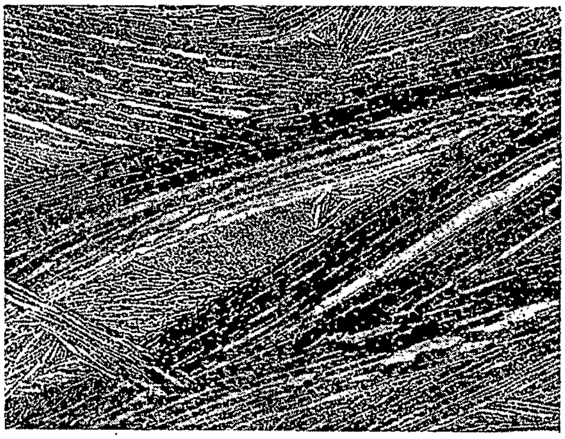

Fig. 2. High-magnification micrograph of part of the same specimen showing the fine structure within the fibres. (× c. 70,000)

It is generally considered[5] that in a soap crystal the molecules are packed with the long chains parallel to the short axis of the crystal, and it has been suggested that in fibres the chains are similarly packed[3]. Using low intensity and low magnification, we have obtained excellent powder patterns corresponding to *hk*0 reflexions only from large areas of both fibre and crystal specimens, which would support the above view that the structures of crystals and fibres are similar.

On the other hand, Bondi and co-workers[6] have proposed an alternative fibre structure in which the chains of the soap molecules are aligned approximately parallel to the width of the ribbon, so explaining the tendency for pure sodium soaps to cleave along the fibre axis. Our electron microscopic observations are more in accord with such a structure. Thus, in Fig. 2, the fibres are made up of ultimate units 30 A. in width (twice the length of a sodium laurate molecule) and the tendency for cleavage, sometimes to fibrils only a few units in width, is clearly illustrated.

We have used selected area electron diffraction of single fibres and crystals in an attempt to resolve this anomaly. Spot patterns of *hk*0 reflexions were obtained from soap crystals, although the crystalline order disappeared rapidly in the electron beam, whereas only diffuse bands were obtained from fibres. It seems possible, therefore, that the large-area diffraction pattern of the fibre specimens was due mainly to a background of sodium laurate crystallites.

The structure of the soap fibres which we have studied thus seems to be different from that of soap crystals, and agrees generally with that proposed by Bondi. As fibres are formed from solution at concentrations well above the critical micelle concentration it is possible that on rapid drying out (as in our work) the micellar character is preserved to some extent in the fibre: the cylinders and spheres which we have observed could be micelles of sodium laurate. Ezaki[7] has proposed a similar structure for fibrous commercial soap. The one technique which could, in theory, resolve this problem—selected-area electron diffraction combined with dark-field microscopy—is not possible under normal conditions of microscopy because of the rapid loss of crystalline order in the fibres. Even large-area diffraction patterns at very low beam intensity disappeared more quickly than those of paraffin wax and fats of much lower melting point. Although the effect cannot, therefore, be due simply to heating, preliminary tests have shown that the fibres are more stable in a cooling stage.

Interaction between Organic Hydroxy Acids and Germanic Acid in Aqueous Solution

A previous communication[1] described the formation in aqueous solution of a number of definite stoichiometric complexes of germanic acid and organic hydroxy acids. These complexes were identified mainly by conductimetric, polarimetric and *p*H measurements. Further work has been carried out on other organic hydroxy acids using the same procedures, and this has resulted in the identification of five more complex acids of germanium. Acids identified are summarized in Table 1.

Crystallization of the complex acids of germanium has proved a difficult task owing to the very high solubility of these compounds in water. Crystalline complex acids in a high state of purity have only

Table. 1

Parent hydroxy acid		Mol. Ge/acid
Glycollic acid	$HO.CH_2.COOH$	1 : 3
Phenyllactic acid	$C_6H_5.(CH_3).C(OH).COOH$	1 : 2
Bromomandelic acid	$C_6H_4Br.CH(OH).COOH$	1 : 3
Benzilic acid	$C_6H_5(C_6H_5).C(OH).COOH$	1 : 2
α-Hydroxy-caprylic acid	$CH_3.CH_2.CH_2.CH_2.CH(OH).COOH$	1 : 2

Table 2

Complex acid	Empirical formula
Germanomandelic acid	$C_{16}H_{20}O_{10}Ge$ (I)
Compound obtained by heating (I) to 140° C.	$C_{16}H_{16}O_8Ge$ (II)
Compound obtained by heating (I) to 190–200° C.	$C_{16}H_{12}O_6Ge$ (III)
Germanobenzilic acid	$C_{28}H_{22}O_7Ge$ (IV)
Germanohydroxycaprylic acid	$C_{16}H_{32}O_8Ge$ (V)
Compound obtained by heating (V) to 150° C.	$C_{16}H_{30}O_7Ge$ (VI)

been obtained when the complexing acid contains a benzene ring or a large number of carbon atoms, for example, mandelic acid, benzilic acid and α-hydroxycaprylic acid.

Results of thermogravimetric and chemical analyses have been combined and empirical formulæ assigned to the crystalline acids (Table 2).

It will be noticed that the three complex acids of germanium and mandelic acid differ from each other by $2H_2O$. The fact that the four molecules of water are given off in two stages seems to indicate that the first two molecules are combined in a different manner from the second two. These observations do not agree with those reported by Mme. O. Vartapetian[2], who did not report any water of crystallization for the complex acid.

A molecule of water of crystallization was found for germanohydroxycaprylic acid, but none for the complex acid derived from germanium and benzilic acid.

Some Methods for the Purification of Sugar Sulphates

Prompted by the recent publication of a communication on the synthesis and purification of certain sugar sulphates[1], we wish to report on some methods for the preparation and purification of these esters which we have found useful in a wider context.

Sulphation of hexoses, or of methyl glycosides, is usually accomplished by the use of chlorosulphonic acid or of the pyridine–sulphur trioxide complex[2]. We have found the latter reagent to be the more satisfactory if the reaction is carried out at a temperature of 60–70° C. for 9–20 hr., using 3 moles of reagent per mole of sugar. Under these conditions comparable amounts of mono- and di-sulphate are produced, but if one hydroxyl group only is available for sulphation the proportion of reagent can be reduced to 1·5 moles.

The product resulting from the direct sulphation of hexoses and glycosides consists of a mixture of non-sulphated sugar, mono- and di-sulphate. This mixture is difficult to separate by methods of precipitation or fractional crystallization and so our attention was directed towards chromatographic and ion-exchange methods. The successful application of ion-exchange resins in the separation of mixtures of sugar phosphates[3] suggested that this method might be employed for separating sugar sulphates; but a detailed investigation led to the conclusion that, while some separation is possible, the method is tedious and the ultimate yield of pure fractions small.

Lloyd[1] has reported that a satisfactory separation of these mixtures is obtained if the sulphuric acid esters derived from the salts are eluted from cellulose columns using a butan-1-ol/acetic acid/water solvent system. We have also found column chromatography to be of value in this respect. In one method, the mixture obtained by direct sulphation of the sugar (galactose, glucose or mannitol) is adsorbed as the neutral barium salts on a column of cellulose powder (Whatman, Standard Grade, previously washed with water, alcohol and ether and dried at 35° C.). Elution with ethanol/acetic acid/water (80 : 1 : 9 by volume) is continued until the unchanged sugar and monosulphate have been separately removed, and thereafter water is used as solvent to hasten elution of the disulphate. In a typical fractionation by this method, the mixture (5 gm.) obtained by direct sulphation of galactose yielded galactose (0·6 gm.), barium galactose monosulphate $[\alpha]_D^{21} + 33°$ (1·1 gm.), and barium galactose disulphate, $[\alpha]_D^{26} + 38°$ (1·7 gm.), each chromatographically and ionophoretically pure.

In the case of the methyl glycosides of glucose and galactose, the separation of unchanged glycoside from glycoside monosulphate is not so complete, although the glycoside disulphate is readily obtained pure. The separation of the glycoside and the glycoside monosulphate can be effected afterwards by the use of ion-exchange resins. Two columns are connected in series, the first containing 'Zeo-Karb 225' (H^+ form) and the second containing 'De-acidite *F*' (free base). Percolation of the mixture of barium salts through these columns results in absorption of the monosulphate on the anion-exchange resin (second column) from which the unchanged methyl glycoside is removed by washing with water. Subsequent irrigation with 2 *N* ammonium hydroxide elutes the glycoside monosulphate, which is obtained as the ammonium salt by cautious evaporation of the eluate *in vacuo*. Similarly, the mixture obtained by sulphation of 1 : 2-3 : 4 di-O-*iso*propylidene-D-galactose is resolved by ion-exchange resins into unchanged starting material and the ammonium salt of the 6-sulphate.

The technique of partition chromatography using 'Celite' as supporting medium[4] can also be used to resolve mixtures of glycosides and their monosulphates. We have used acid-washed 'Celite 535' (Johns-Manville Co.) as adsorbent with butanol saturated with water as eluting solvent to separate a mixture of α-methyl glucoside and its monosulphate. This method suffers from the disadvantage that the columns have a rather low loading capacity.

For the routine qualitative examination of sulphation mixtures, the method of paper-ionophoresis has the advantages over paper-chromatography of speed and simplicity. A satisfactory resolution of galactose, its monosulphate, and its disulphate is obtained on Whatman No. 54 paper, using 0·067 *M* phosphate buffer (*p*H 6·8) as electrolyte and a potential gradient of 10 volts/cm. for 3–4 hr. Carbohydrate zones are detected by the silver nitrate reagent of Trevelyan, Procter and Harrison[5]. Similar results are obtained with other sulphation mixtures, but the method is not capable of separating two monosulphates.

We wish to thank Prof. Stanley Peat for his advice and the National University of Ireland for the award of a travelling studentship to one of us (M. J. C.).

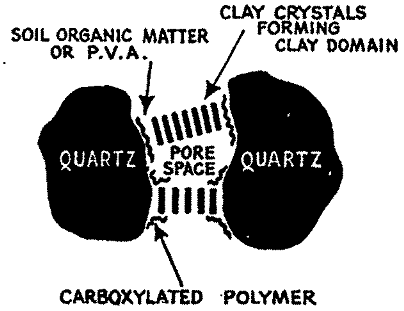
SOIL SCIENCE

Stability of Soil Crumbs

Tiulin[1] showed that the stability of soil crumbs in water is greater from grassland than from corresponding arable soils. Since then, much work has been done to find out how this increase in stability is brought about by the soil organic matter. A review of this work is given by Baver[2]. In recent years it has been discovered that small additions to the soil of various synthetic polymers, called soil conditioners, also stabilize soil crumbs. The polymers can be either non-ionic, such as polyvinyl alcohol[3], or carboxylated polymers, such as polyacrylic acid[4].

It is now suggested that both soil organic matter and soil conditioners increase the stability of soil crumbs by linking together the principal constituents of the crumbs, the domains of orientated clay and the quartz particles. The linkages will be from the surfaces of the quartz to either the external basal or external edge surfaces of the clay domains, forming inter-crystalline or peripheral complexes[5,6] respectively (Fig. 1).



CLAY CRYSTALS FORMING CLAY DOMAIN
SOIL ORGANIC MATTER OR P.V.A.
QUARTZ
PORE SPACE
QUARTZ
CARBOXYLATED POLYMER

Fig. 1. P.V.A., polyvinyl alcohol

The model proposed satisfies the following known features of soil-crumb behaviour.

(1) The arrangement of the soil matrix is the same in both arable and grassland crumbs, both kinds of crumbs yielding similar thin sections[7] and similar moisture-release curves[8]. Untreated and conditioner-treated crumbs also give similar moisture-release curves[9]. (2) The crystalline water uptake and, therefore, the crystalline swelling of the clay is the same in arable and grassland crumbs, as well as crumbs stabilized by a carboxylated polymer[7]. (3) Slaking of the grassland or of conditioner-treated crumbs is reduced[10], for the stresses set up on wetting a dry crumb due to the crystalline swelling of the clay will be shared between several clay domains, through their linkages to the same quartz particles. (4) If the clay is sodium-saturated, the diffuse double-layer swelling is reduced sufficiently by the proposed quartz–organic material–clay linkages to prevent dispersion of the grassland or conditioner-treated crumbs in water[11]. (5) Remoulding grassland or conditioner-treated crumbs by breaking further quartz–clay linkages reduces the strength of the crumbs as measured by any conventional wet sieving or dispersion technique[12].

The model also offers a satisfactory way of accounting for the physical action and economy of soil conditioners. When a solution of a soil conditioner is added to a dry crumb, the consequent slaking will break the weakest clay–quartz bonds, so producing readily available sites for adsorption of the polymer. These sites are, at the same time, the most advantageous for increasing crumb stability.

The detailed presentation of this model with some of its consequences will be published elsewhere[13]. The model is incomplete, in that the chemistry of the linkage of the organic material to the quartz is not specified. There are other methods of stabilizing crumbs, for example, by using quaternary ammonium salts to inhibit the crystalline swelling of the clay[14].

Latent Interparticle Forces in Clays

Work in colloid science is usually concerned with clays in suspension, where external stresses are negligible. Experimental work in soil mechanics has shown that in consolidated and compacted clays both the existing external effective stress and the stress history are most important in determining soil properties[1,2].

If the pressure of pore water in a saturated clay is zero, the external stress σ_E must be balanced by a net intergranular repulsion σ_I:

$$\sigma_E - \sigma_I = 0 \qquad (1)$$

Fig. 1 shows the virgin consolidation curve *ABCDE* and three rebound curves *BF*, *CG* and *DH* for a clay initially prepared at a high water content. Each point on the virgin consolidation curve and on any rebound curve is an equilibrium point with zero pressure of pore water. At any voids ratio ε_1, σ_E may have any value within a wide range (for example, σ_a, σ_b, σ_c, etc.), the maximum being the virgin consolidation value σ_{NC}. It follows from equation (1)

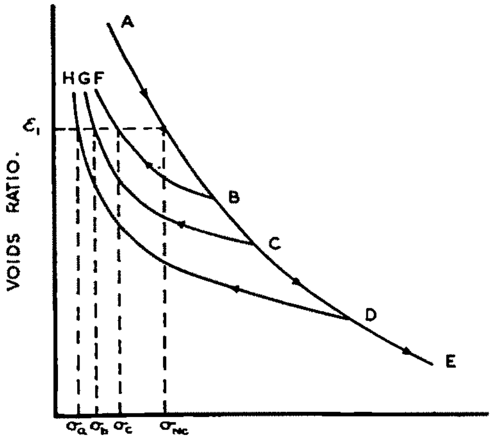

Fig. 1

that σ_I must also have a range of possible values at any voids ratio, with a maximum value $\sigma_{I\max.}$ at the virgin consolidation condition. During rebound the repulsive stress is less than $\sigma_{I\max.}$ so that an additional internal attractive stress σ_{AL} is acting. Equation (1) becomes :

$$\sigma_E - \sigma_{I\max.} + \sigma_{AL} = 0 \qquad (2)$$

At any voids ratio, σ_{AL} will have a maximum possible value $\sigma_{L\max.}$ This is termed the total latent stress. The active portion at any time, σ_{AL}, is the active latent stress and the inactive portion ($\sigma_{L\max.} - \sigma_{AL}$) is the latent stress σ_L.

This attractive stress associated with swelling may arise from particle orientation or from the fact that interparticle forces are not only a function of particle spacing but also of the previous history of particle spacing. Orientation is difficult to support for isotropic consolidation and rebound, and the second possibility is more likely.

In a normally (that is to say, virgin) consolidated clay the latent interparticle forces are completely inactive, and in a heavily prestressed clay they are completely active. In the former case an applied shear stress is resisted by the latent forces becoming active between particles with increasing spacing due to the shear strain, and in the latter case it is resisted by the active latent forces becoming absorbed between particles with decreasing spacing. This leads to a decrease in volume in normally consolidated clays and an increase in volume or dilation in heavily prestressed clays. This behaviour during shear is well known for clays.

Ultimately a unique state is reached, regardless of the initial condition, where the latent forces are fully active between one half of adjacent pairs of particles and completely inactive between the other half. This gives a unique internal and, hence, external stress condition σ_{CVR} for any voids ratio. Experimental evidence for this has been published[3,4].

From the theory of latent interparticle forces it can be shown that the shear strength on an interface is given by the expression :

$$s = \mu(2\sigma_{NC} - 3\sigma_{CVR}) + \mu\sigma_n \qquad (3)$$

where σ_n is the direct effective stress on the interface.

Thus, the strength is composed of two portions : $\mu(2\sigma_{NC} - 3\sigma_{CVR})$, which depends only on voids ratio ; and $\mu\sigma_n$, where μ is an arbitrary constant independent of voids ratio. These portions correspond with Hvorslev's[1] true cohesion and true friction, respectively, but it can be seen from the theory above that these do not represent two different origins of strength. A form of equation (3) suitable for triaxial tests has given excellent agreement with results from Weald clay and London clay.

As latent forces are probably present in all materials which can resist shear stress, it is reasonable to look for their origin in the universal London - van der Waals attractive forces. When two atoms approach each other there may result a mutual disturbance of electron clouds, which is not reversible when separation of the two atoms is again increased. This may result in an attractive force tending to oppose the separation of the atoms.

A discussion of the role of latent interparticle forces in clays will shortly be published elsewhere.

BIOCHEMISTRY, PHYSIOLOGY and MEDICAL SCIENCES

Radiation Protection and Free Radicals

Free radicals formed in biological materials by ionizing radiation may be detected under the proper conditions by paramagnetic resonance techniques. Possibly such free radicals contribute, directly or indirectly, to the radiation damage suffered by living organisms. The various chemicals which have been found to increase the survival of organisms subjected to large doses of radiation may provide protection by action on the free radicals or by some more direct action on the substance of the organism. This report describes experiments made to see if paramagnetic resonance detection of free radicals could be used to study chemical protection against ionizing radiation.

The paramagnetic resonance equipment uses conventional microwave circuitry[1] operating at 9,000 Mc./sec. and dual modulation of the magnetic field[2]. Yeast suspensions were chosen for study because they survive freezing and are easy to handle. β-Mercaptoethylamine was the protective chemical used. Small samples of the material to be examined were quickly frozen after mixing and were irradiated at liquid-nitrogen temperature in a cobalt-60 gamma chamber, then transferred to unirradiated sample tubes for the paramagnetic resonance measurements at 77° K.

On irradiating a suspension of yeast in water, we found the expected doublet resonance due to the irradiated water and a broad line of 25 gauss width near $g = 2{\cdot}00$. An irradiated solution of β-mercaptoethylamine also showed the water doublet and a 25-gauss line at only a slightly higher g-value—too small a difference to distinguish the yeast from the β-mercaptoethylamine with both present. It seemed possible that the width of these lines was a result of

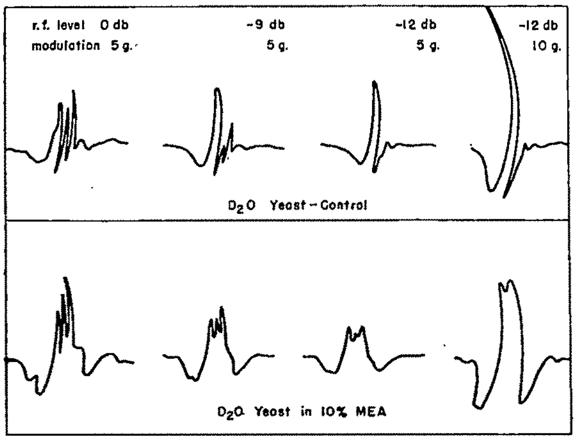

Fig. 1. Saturation effect on yeast signal. Samples Co-60 γ-irradiated 1 hr. at 77° K. for 150,000 r. total dose. Observed at 77° K. MEA, β-mercaptoethylamine; r.f., radio frequency; db, decibels

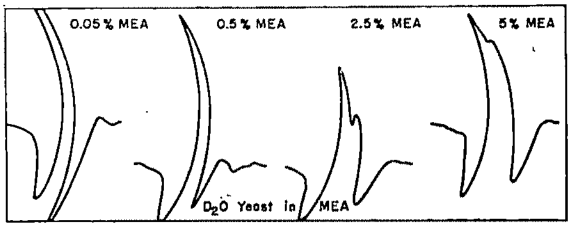

Fig. 2. Effect of β-mercaptoethylamine concentration on yeast and β-mercaptoethylamine signal intensity. MEA, β-mercaptoethylamine. Sample treatment as for Fig. 1

unresolved hyperfine structure due to adjacent hydrogens of the radical. If this were the case, replacing hydrogen with deuterium would narrow the line because the deuteron has a smaller nuclear moment than the proton. We were therefore fortunate in being able to get a generous supply of yeast (*Saccharomyces cerevisiae*) grown in deuterium oxide. (We wish to thank Harry L. Crespi of this Laboratory for the deuterium-grown yeast used in these experiments.) This, when irradiated, gives a signal only 9 gauss wide in addition to the water signal, which is now a triplet (deuteron spin = 1).

Fig. 1 shows how their differing saturation properties may be used for suppressing the water signal and enhancing the yeast signal. In the upper row, beginning on the left with maximum radio-frequency power incident on the sample and the magnetic field modulation adjusted for optimum signal, as the ratio-frequency power is reduced the water triplet is seen to diminish and the yeast line to increase in intensity. The right-hand trace shows an additional increase in the yeast signal by increasing the magnetic field modulation. The lower row shows the same sequence for a sample having 10 per cent by weight β-mercaptoethylamine added before irradiation. On the left is the water triplet sitting on top of the broad β-mercaptoethylamine line. As power is reduced the triplet diminishes, the β-mercaptoethylamine signal remaining constant. On the right, increasing the modulation increases the β-mercaptoethylamine signal. The yeast signal is seen as a small pip on the side of the β-mercaptoethylamine line, indicating, due to the presence of the β-mercaptoethylamine, a decrease in the number of yeast free radicals.

Fig. 2 shows the effect of concentration of β-mercaptoethylamine on both yeast and β-mercaptoethylamine signals. At 0·05 per cent β-mercaptoethylamine the yeast signal is unaffected and the β-mercaptoethylamine signal cannot be seen. Increasing the concentration of β-mercaptoethylamine to 0·5 per cent brings a 10 per cent reduction in the yeast signal and a small indication of the β-mercaptoethylamine on the right side of the trace. At 2·5 per cent β-mercaptoethylamine the yeast signal is reduced by half and the β-mercaptoethylamine signal becomes comparable to it. Increasing the β-mercaptoethylamine to 5 per cent doubles its signal and brings the yeast signal down to 20 per cent or less of its original value. Although not shown in this figure, the water signal is independent of concentration of β-mercaptoethylamine.

From previous work we knew that free radicals produced in water at 77° K. were unstable at 125° K. After annealing at the latter temperature for 1 min., the water signal had disappeared but there was no change in the yeast or β-mercaptoethylamine signals.

We have then: (1) The presence of β-mercaptoethylamine inhibits free radical formation in irradiated yeast. (2) The ½ min. required to add β-mercaptoethylamine to yeast and freeze is time enough for the protection to be established. (3) The β-mercaptoethylamine has no effect on the number of radicals formed in the water of the suspensions. (4) The water radicals, on gaining mobility at 125° K., do not react with the yeast radicals or β-mercaptoethylamine radicals. These observations support the view[4] that the protective effect is not primarily due to inactivation of the products of irradiation of water but rather to direct action of the protective agent on radiosensitive constituents, for example, cell protein.

Absence of a Relation between Lipogenesis and Ketogenesis *in vivo*

IN the normal liver acetyl-coenzyme *A* is formed from glucose, fatty acids and the keto-acids produced by deamination and transamination of amino-acids. It is removed by oxidation, by fatty acid synthesis and, to a small extent, by ketone body formation (Fig. 1). Lipogenesis is defective in the livers of diabetic and fasting animals, a block occurring in the path of conversion of acetyl-coenzyme *A* to fatty acids[1]. Formerly, many workers related the development of ketosis to a diminished rate of oxidation of acetyl-coenzyme *A*, due to a possible lowering in the level of oxaloacetate. Lately, as a result of experiments *in vitro*, increased ketogenesis has been attributed to a diversion in the utilization of acetyl-coenzyme *A* (or acetoacetyl-coenzyme *A*) from fatty acid synthesis towards the formation of ketone bodies[2-4]. Stadie[4] has advanced the hypothesis that the supply of reduced triphosphopyridine nucleotide, which depends upon the rate of glucose metabolism via the hexosemonophosphate 'shunt', regulates fatty acid synthesis and, consequently, ketogenesis.

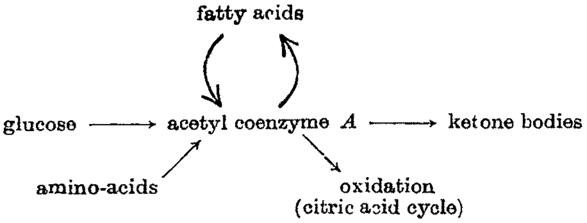

Fig. 1

There is little evidence to show that diminished hepatic lipogenesis is responsible for increased ketogenesis *in vivo*. The lipogenesis theory of ketone-body formation lays emphasis on the under-utilization, rather than on the over-production of acetyl-coenzyme *A* by the liver. However, it is difficult to explain, other than by accelerated oxidation of fatty acids (giving rise to over-production of acetyl-coenzyme *A*), the enormous formation of ketone bodies which is necessary to account for extra hepatic utilization-rates representing 50–96 per cent of the body's oxygen consumption during starvation[5], or for the very heavy ketonuria of severe diabetics[3]. It is difficult to visualize how restoration of the normal rate of hepatic lipogenesis would have more than a moderating influence under these conditions. Since lipogenesis is defective in the livers of animals fed diets devoid of carbohydrate[1], the following experiments with rats on an all-fat diet are relevant to this problem.

Female rats (200 gm.) were fasted for 24 hr. and then given filtered butter-fat *ad libitum* for six days. Experimental details have been published previously[6]. The ketonæmia initiated by starvation continued to rise on feeding fat, but in animals consuming approximately 6 gm. a day a marked reduction was observed after the first day of feeding (Fig. 2). In contrast the ketonæmia of rats which ate less of the diet remained elevated. The ketonæmic responses of animals consuming 6 gm. a day fell into two categories. In one, illustrated by rat *A* (Fig. 2), there was a return to within the normal ketonæmic range, usually on the fifth day of feeding fat. The other, illustrated by rat *B* (Fig. 2), is typical of animals showing a higher initial ketonæmia which dropped afterwards but remained slightly elevated on the fifth day. There was a tendency for the ketonæmia to rise a little in all animals on the sixth day of feeding.

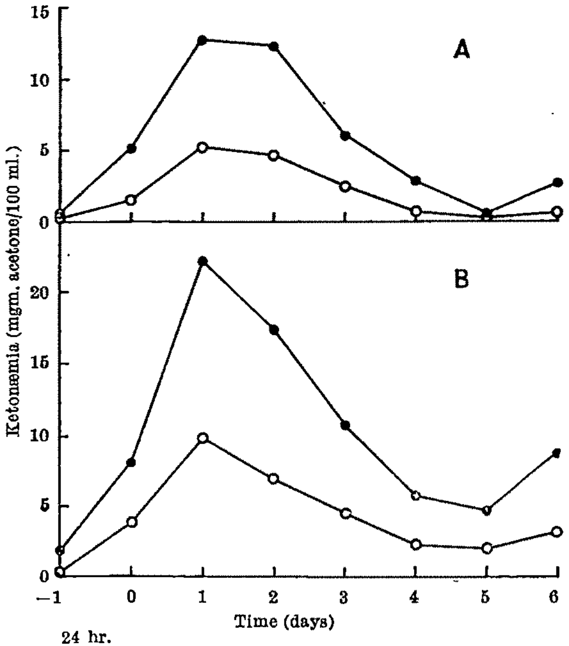

Fig. 2. The course of ketosis in rats starved for 24 hr., which then consumed approximately 6 gm. of butter-fat per day. ●, β-Hydroxybutyric acid; ○, acetone plus acetoacetic acid

The observation of a much reduced ketosis and sometimes its abolition under conditions in which fatty acid synthesis is considered to be defective provides direct evidence that a reduced rate of hepatic lipogenesis is not, necessarily, the major cause of ketosis *in vivo*.

Stability of Cholinesterase of the Electric Eel

A CONVENIENT source of the enzyme acetylcholinesterase occurs in the electric organ of the electric eel, and preparations of a high degree of purity have been obtained from it[1]. Because of the high activity of these preparations and the sensitive methods available for the estimation of enzymatic activity, appreciable dilutions of the enzyme must often be made. It has been found that dilution causes a rapid loss of enzymatic activity, and the addition of an inert protective protein such as gelatine has been recommended[1]. Further studies[2] have revealed that low ionic strengths also produce inactivation and that protection is afforded by plasma albumen[3].

Present investigations into this effect have shown that inactivation in dilute enzyme solutions is primarily a surface phenomenon. Because of the obvious importance of this observation in the preparation and estimation of this enzyme, it is felt that this fact should be emphasized.

The sample was one kindly supplied by the U.S. Army Chemical Centre, Edgewood, Md. and had an activity of 46 gm. of acetyl choline/hr./ml. at 37° C., determined manometrically. It contained 3·97 mgm. of protein/ml. in approximately 6 per cent ammonium sulphate. This sample has remained stable and of the same activity over a period of 1½ years when kept at about 3° C. Enzymatic activity was estimated manometrically using the following conditions: 1·5 ml. 0·05 *M* sodium bicarbonate, 0·5 ml. 0·6 *M* sodium chloride, 0·1 ml. 0·6 *M* magnesium chloride, 0·1 ml. 3 per cent bovine plasma albumen, 0·1 ml. 0·3 *M* acetyl choline bromide, an aliquot of the enzyme solution and water to give a final volume of 3·0 ml. The gas phase was 5 per cent carbon dioxide in nitrogen, which gave a *p*H of 7·43 at 37° C.

Stock enzyme solution was diluted 2,000 times in different solutions, and the activity estimated after two different treatments and compared with controls diluted in the same solutions. In one treatment the solutions were shaken in small stoppered tubes for 1 hr. at room temperature, while the other treatment consisted of bubbling nitrogen through the solutions for 30 min.

The diluting mediums were as follows: *a*, 6 per cent ammonium sulphate solutions adjusted to *p*H values of 5·4, 7·4 and 9·0; *b*, 0·1 per cent bovine plasma albumen, or gelatine; *c*, 0·02 *M* veronal buffer of *p*H 7·4 containing 0·3 *M* potassium chloride and 0·1 per cent bovine plasma albumen; and *d*, 0·3 *M* potassium chloride.

The results of both treatments are shown in Table 1.

Table 1. Loss of Enzymatic Activity

Solution	Treatment Nitrogen bubbling (Activity lost, per cent)	Shaking
a	85–97	75–95
b	2	2
c	0	0
d	95	90

It is clear that, in either solutions *a* or *d*, shaking or bubbling by nitrogen rapidly inactivates the enzyme. This inactivation would appear to be a surface phenomenon and not an oxidation process. The dilute control solutions in ammonium sulphate do not show any appreciable loss of activity if care is taken to avoid excessive agitation in their preparation. Protection is afforded to the enzyme by either bovine plasma albumen or gelatine. It is standard practice in this laboratory to make dilutions of acetylcholinesterase in the veronal buffer solution *c* in which the enzyme is stable for 1–2 weeks when kept in the cold.

Neuromuscular Blocking Agents of Short Duration

For a number of years we have been interested in the neuromuscular blocking properties of *bis*-onium compounds derived from substituted tropane nuclei, in which linking of the quaternary nitrogens was effected by a polymethylene or aralkyl chain. We observed that such compounds produced a flaccid paralysis on injection into chicks but tended to be long acting. This observation led to the preparation of a series of similar compounds (Fig. 1) in which the linking chain contained two ester-groupings as in suxamethonium. The latter is known to produce short-acting block which is, however, of depolarizing character.

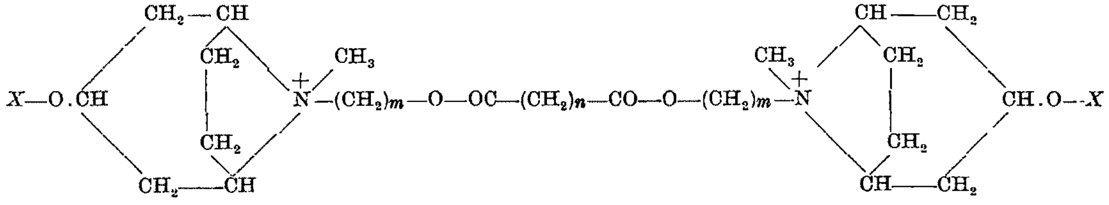
Table 1. Doses of *D.F.* 596 required to produce Paralysis in Different Species

Species	Test	Intravenous dose mgm./kgm. with limits of error ($P=0·05$) *D.F.* 596	*d*-Tubocurarine chloride
Mouse	Dose causing 50 per cent of animals to fall from an almost vertical wire mesh screen within 1 min. of injection	0·23 (0·21–0·25)	0·041 (0·037–0·046)
Rat		0·40 (0·36–0·44)	
Rabbit	Dose causing head drop in 50 per cent of animals after a single rapid injection	0·16 (0·13–0·20)	
	Mean head-drop dose after slow infusion		0·18 (0·15–0·20)
Cat	Mean dose giving 50 per cent depression of gastrocnemius twitch	0·36 (0·28–0·46)	0·2* approx.
Dog		0·089 (0·061–0·117)	0·1 approx.

* Because of the cumulative action of *d*-tubocurarine this value was estimated from the initial dose injected into each animal.

Subsequent tests confirmed that several of the above substances combined the desirable short-acting property of suxamethonium with the competitive blocking action observed in other series of *bis*-tropinium compounds. Duration, potency and effects on blood pressure were found to be determined by the composition of the chain and the terminal acyl radicals. Short duration, low potency and marked hypotensive properties were favoured by high values of *n*, and greatest potency appeared to be associated with chains equivalent to 12 or 13 carbon atoms in length.

One of the most promising members of the series from the point of view of duration and potency was *D.F.* 596 (*X*, phenylacetyl; *n*, 4; *m*, 2). Doses of this compound required to produce paralysis after a single intravenous injection were determined in various species and are given in Table 1. By direct comparison it was found to be slightly more active than *d*-tubocurarine chloride in the dog and about half as potent in the cat. Duration of paralysis was comparable with that of suxamethonium and cumulative effects were not observed. Injection of doses which almost completely abolished the gastrocnemius twitch caused a fall in blood pressure and mydriasis of short duration in cats, but these effects were only slight in dogs. By administering the compound to rabbits as an intravenous infusion, it was possible to obtain head drop and what appeared to be complete recovery four times within 40 min.



X, Acyl radical; *m*, 2–3; *n*, 1–6.

Fig. 1

Neuromuscular block in cats and dogs due to *D.F.* 596 was antagonized by neostigmine, edrophonium, suxamethonium and decamethonium and augmented by ether and *d*-tubocurarine. During partial block the response to a tetanus was poorly maintained. The compound did not cause a contracture of chicken gastrocnemius or frog rectus abdominis muscle but antagonized contractures produced by suxamethonium on the former and by acetylcholine on the latter.

Rabbits anæsthetized with urethane and maintained by artificial ventilation tolerated large doses of the compound ; six animals which received a single intravenous injection of 100 mgm./kgm. were still alive 6 hr. later when ventilation was discontinued. In each case spontaneous respiration returned.

A full account of the work carried out on this and other closely related series will be published elsewhere. Patent applications are pending.

Entropy and Synovial Pathology

Previous *in vitro* experiments on synovial metabolism have shown that the presence of rheumatoid disease in the synovial membrane resulted in marked metabolic changes[1]. The rate of uptake of oxygen was greatly altered by the presence of the disease, for example, normal synovium (of traumatic origin) Qo_2(N) 1·0 up to Qo_2(N) 35·0 in very active disease states. A crude relationship was found to exist between the macroscopic appearance of the pathological material and the rate of uptake of oxygen. As the change in uptake of oxygen was so marked in the rheumatoid synovia, we felt that some quantitative relationship might exist between the rate of uptake of oxygen and the state of the disease. The problem, therefore, was to obtain a quantitative method for expressing the pathological changes in the diseased synovium.

Rheumatoid arthritis is characterized locally by the occurrence of hypertrophy in the synovial and stromal layers, the appearance of round cell foci, plasma cells and to a lesser extent leucocytic infiltration in the subsynovium. The numbers of these various cell types vary greatly in different stages of the disease. Herdan[2] has shown that a quantity H, termed 'entropy' because of its formal similarity with the entropy of statistical mechanics, may be used for expressing changes in the pattern of serum proteins in pathological conditions and, more generally, could be used as a measure of pathological disorder. The entropy of the mixture, H, is calculated as the expression:

$$H = - \Sigma p_i \log_2 p_i$$

where p_i represents the proportion of a constituent. We have applied this expression to the synovial cytology of normal and pathological material. The cellular proportions were obtained by a standardized counting technique, the details of which will be reported in full elsewhere. The error of estimate was found by obtaining 25 separate estimates of H from a typical rheumatoid synovium. For this tissue the mean H was 1·989 and the standard error of the mean 0·023. H was calculated routinely from 10 separate estimates of the cellular counts in a variety of normal and rheumatoid synovia.

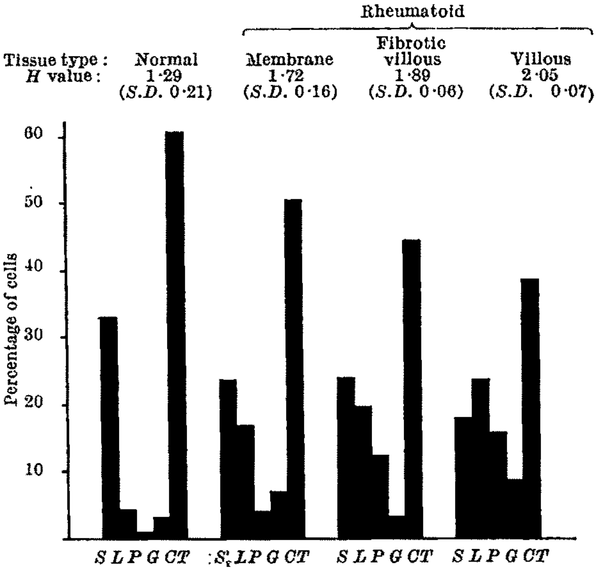

Fig. 1. The distribution of certain cell types in normal and rheumatoid synovia, together with their mean entropy values (H). S, Synovial cells; L, lymphocytes; P, plasma cells; G, granulocytes; CT, connective tissue cells; $S.D.$, standard deviation

Fig. 1 shows the average distribution of certain cell types in normal and rheumatoid synovial tissue. The rheumatoid synovia have been classified macroscopically as previously described by Dingle and Page Thomas[3]. Rheumatoid tissue shows a greater tendency to equidistribution of cell types, which is most marked in the villous material. The mean entropy values H were calculated for each of these distributions, and it may be seen that the value of H rises as the cellular content becomes more abnormal. Fig. 2 shows an application of this result to 19 different rheumatoid synovia of varying metabolic activity. There is a correlation between log Qo_2(N)

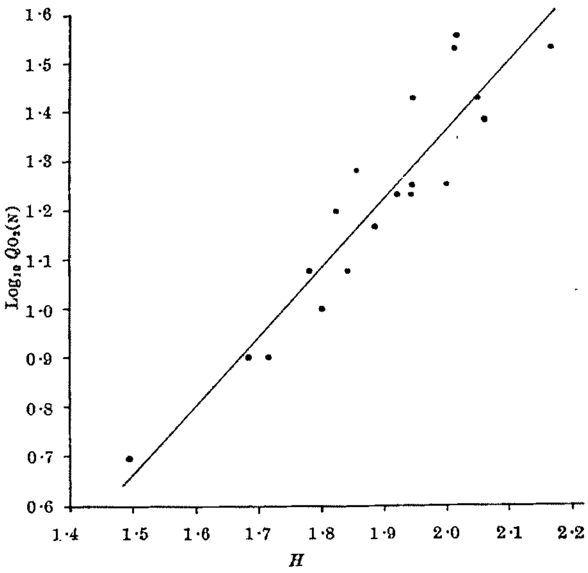

Fig. 2. The correlation of oxygen uptake with 'entropy' value for nineteen rheumatoid synovia

and H over a wide range of metabolic activity. The regression equation is $y = 1{\cdot}38x - 1{\cdot}41$, $r = 0{\cdot}95$, $P < 0{\cdot}001$. Thus it would appear that H can be usefully employed as a criterion of the disease state in terms of the extent of pathological disorder, especially where information is required as to the relationship between the cellular composition and the experimental findings.

Distribution of Melanophore-aggregating Hormone in the Pituitary of the Minnow

The melanophore-aggregating hormone of the pituitary of *Gadus callarias*[1] and *Cyprinus carpio*[2] has been shown to be concentrated in the meta-adenohypophysis (pars intermedia). In *Parasilurus asotus* the hormone is concentrated in the meso-adenohypophysis (*Übergangsteil*)[3]. Spinal-sectioned minnows (*Phoxinus phoxinus*) are able to maintain the white background response after hypophysectomy provided some of the anterior part of the pituitary remains after the operation but not if the whole pituitary is removed[4].

In ventral view the minnow pituitary is seen to be divided into an anterior opaque region with few superficial blood vessels, corresponding roughly to the histological divisions of pro- and meso-adenohypophysis, and a less-opaque posterior region with considerable superficial vascularization corresponding roughly with the meta-adenohypophysis (Fig. 1).

Minnows (55–65 mm. long) taken from a stock maintained in a white tank were decapitated and the pituitaries exposed by removal of the floor of the mouth. With the aid of a small piece of razor blade attached to a glass rod, the pituitary was swiftly divided into two portions with a single cut along the line separating the two regions described above ($X - X'$ in Fig. 1). The two portions were removed and separately homogenized in 0·1 ml. of distilled water. The procedure, from decapitation to the separation of the two portions, was completed in 20–30 sec.

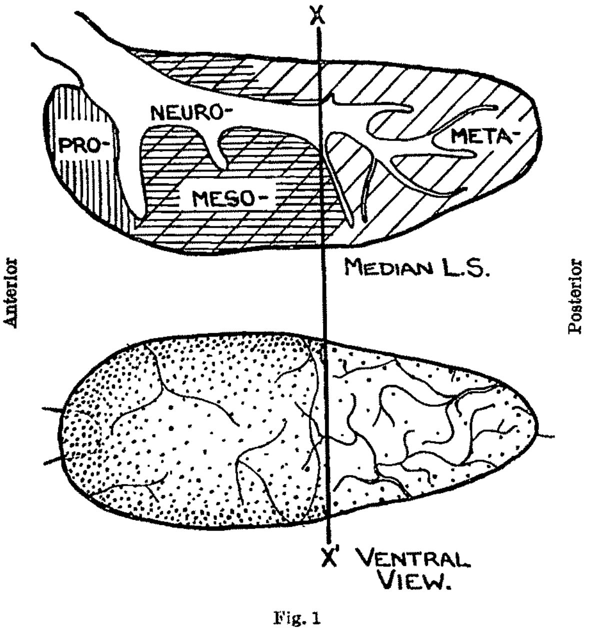

Fig. 1

Table 1

Response of B region melanophores of black-adapted minnows	Pituitary region	
	Anterior	Posterior
Change in melanophore index 1 hr. after injection	0·0	1·2
	0·0	2·6
	1·8	1·4
	0·4	2·8
	0·4	2·0
	1·4	3·0
	0·0	0·4
	1·2	1·0
	0·2	1·4
	2·0	2·6
	0·0	0·4
	2·0	1·8
	0·6	2·8
	0·0	1·4
	0·2	2·6
Mean	0·68	1·83
S.D.	0·777	0·878
	$P < 0{\cdot}01$	

The whole of the homogenate was injected into the body cavity of black-adapted minnows (60–65 mm. long). The melanophore index of the region B micromelanophores[5] of each individual was read immediately prior to injection and again 1 hr. after injection. The results are summarized in Table 1. In 10 out of 15 cases the posterior region of the pituitary showed greater melanophore-aggregating activity than the anterior region, while in five cases the responses were more or less equal.

Of particular interest is the fact that the melanophore-aggregating activity was detectable in both regions of the pituitary. In view of the short period of time elapsing between decapitation of the fish and separation of the two portions of the pituitary (30 sec.) it seems unlikely that appreciable diffusion of the hormone could have occurred. This suggests, in the light of Healey's observations[4], that the melanophore-aggregating hormone is produced in the anterior part of the pituitary and passed to the posterior part for storage.

Enami's observation[3] that the melanophore-aggregating hormone in *Parasilurus* has its origin in the nucleus lateralis tuberis of the hypothalamus suggests that a similar arrangement may occur in the minnow. Experiments aimed at detecting melanophore-aggregating activity in the minnow hypothalamus have been unsuccessful. While this does not preclude the possibility that the hormone is present in amounts too small to detect, it suggests that an alternative explanation may have to be sought to account for the condition in this species. The occurrence of large ganglion cells in the anterior part of the minnow neurohypophysis such as have been described in *Salmo* and *Gadus* and the apparent absence of a nucleus lateralis tuberis indicate a possible extra-hypothalamic source of neurosecretion. It is clear that further evidence is necessary before a final judgment can be made regarding the role of these cells in the production of the melanophore-aggregating hormone. Experiments aimed at obtaining such evidence are now in progress.

Acknowledgments are due to Dr. E. G. Healey for supervision and to the Department of Scientific and Industrial Research for a research scholarship.

Gibberellins and Nodulation

Recently, Fletcher, Alcorn and Raymond[1] presented evidence that gibberellins had no effect on the nodulation of white clover (*Trifolium repens*) grown either in aseptic agar or in soil. In concentrations from 1 to 1,000 p.p.m., gibberellic acid was also without effect on the growth of the nodule-forming organism *Rhizobium trifolii*. These combined results seemed to contradict a previous report of Thurber, Douglas and Galston[2], who had found a marked depressive effect of potassium gibberellate on nodulation in dwarf beans (*Phaseolus vulgaris*).

Although I have done no further work on this phenomenon since the original report, I have been in receipt of information from other workers in the field, who have corroborated and extended our findings. For example, Dr. P. W. Brian, of Imperial Chemical Industries, Ltd., has informed me that 10 and 100 p.p.m. sprays of gibberellic acid, applied daily or weekly, greatly depressed the number of nodules and the mean diameter of nodules of 14-day old plants of *P. vulgaris* var. Masterpiece grown in garden soil.

Similarly, Dr. N. P. Kefford, of the Commonwealth Scientific and Industrial Research Organization, Division of Plant Industry, Canberra, has found a depressive effect of gibberellic acid at 0·3 p.p.m. on nodule formation of lucerne (*Medicago sativa*, Hunter River) grown for 42 days on mineral agar, the acid in these experiments being added directly to the agar. In this case, the fewer nodules were each of larger volume than the controls, so that the nodule volume per plant was unaltered by treatment with gibberellic acid. Both Dr. Brian and Dr. Kefford plan to publish their results in detail.

In view of these results, involving independent demonstration of the same kind of phenomenon in three widely separated laboratories, it would seem that the original conclusion that gibberellins can inhibit nodulation is valid, and that some care is therefore required in the use of this product on legumes. It is also clear from the work of Fletcher *et al.* that not all legumes grown under all conditions will show this inhibitory effect of gibberellic acid. This difference in nodulation response is probably related to the already known fact that different genotypes of plants, presumably of varying endogenous gibberellin-levels, react quite differently to identical gibberellin applications.

Quantitative Measurement of the Effect of Lysergic Acid Diethylamide on Mice and its Interactions with other Drugs

Although several species of animals (including spiders, fighting fish, pigeons and rats) have been used for the quantitative evaluation of the effect of hallucinogenic and psychotomimetic agents it is worth while to add to this list owing to the biochemical differences between species. The present favourite seems to be the rat[1]. This communication reports a test for the quantitative evaluation of the effect of psychotomimetic agents using mice chosen for their small size (useful if limited quantities of agent—for example, extracts from schizophrenic serum—are available) and ease of handling. A Latin square design was used employing four cages, each of 5 mice, and four modes of injection (saline, lysergic acid diethylamide, drug to be tested, and lysergic acid diethylamide and this drug together). The mice were injected subcutaneously and placed individually on the centre of a vertical pole at 1 min. intervals. The time (up to a maximum of 40 sec.) taken by the mice to reach lines drawn 1 in. from the top or bottom of the pole was then measured. Variability can be reduced by eliminating slow or erratic mice in preliminary tests. (The mice can also be trained to run down the pole under hunger drive. This procedure, however, introduces two new parameters—learning and hunger—which may be differentially affected by drugs.) Doses of lysergic acid diethylamide of 1 and 2 mgm./kgm. were used. The solutions were always freshly prepared and the effect tested of their interaction with adrenochrome, adrenolutin and the brom derivative of lysergic acid diethylamide. Fig. 1 shows the difference between the drug value and its matching saline value, with the latter corrected to a straight line at the level of the first saline value (maximum possible score = 200). All statistical work was done, however, on uncorrected results. As the results obtained were not normally distributed, all statistical evaluations were carried out using non-parametric methods (Wilcoxon's method for paired data).

It was found that lysergic acid diethylamide increases the time which the mice take to reach the end of the pole. This is maximum at 10–15 min. after injection and is still appreciable after 30 min. Bufotenin in doses up to 20 mgm./kgm. did not show any of this effect (nor any qualitative change). Adrenochrome in doses of 10 and 20 mgm./kgm. has no effect on mice demonstrable by this test or on the effect of lysergic acid diethylamide on mice. Adrenolutin inhibits the effect of lysergic acid diethylamide on mice but exerts no influence by itself in a dose of 20 mgm./kgm. (Fig. 1). This effect was confirmed in a further experiment using 40 trained hungry mice and 30 mgm./kgm. adrenolutin (P for the interaction of lysergic acid diethylamide and adrenolutin is between 0·02 and 0·05). The brom derivative of lysergic acid diethylamide in a dose of 1 mgm./kgm. produced a marked sedation of untrained mice and a delayed time for descending the pole. The same dose did not produce this effect in trained or hungry mice where, presumably, the sedative effect could be overcome by motivation or training. The morpholide derivative of lysergic acid diethylamide is less active but causes a late acceleration of the mice (at 30–60 min.: $P = 0·02$).

The purpose of this test is to evaluate the effect of lysergic acid diethylamide and other psychoto-

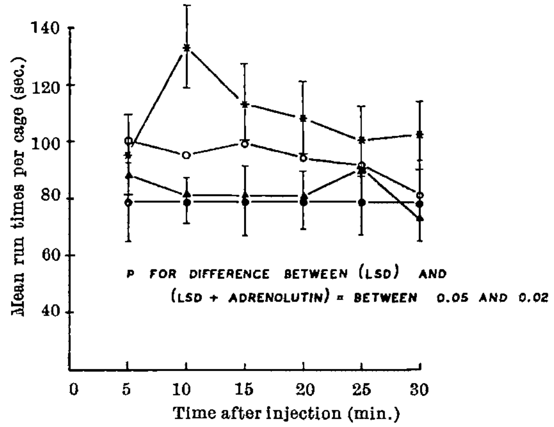

Fig. 1. Showing the effect of lysergic acid diethylamide (LSD), adrenolutin and their interaction. Cages *A–D*, each point representing 40 mice: ●, saline; ★, LSD (1 mgm. per kgm.); ▲, adrenolutin (20 mgm. per kgm.); ○, LSD + adrenolutin

mimetic agents quantitatively and to measure their interaction in mice. Inferences from these results to humans can only, of course, be made with caution. These experiments indicate that adrenochrome and adrenolutin (in the doses used) do not act on mice as lysergic acid diethylamide does and that they do not potentiate this action of lysergic acid diethylamide or vice versa (it has been claimed[2] that lysergic acid diethylamide in man potentiates the effect of adrenolutin). However, bufotenin, a known human hallucinogen, has no demonstrable effect either in mice even in large doses.

I am grateful to Dr. Harold E. Himwich and to Dr. Erminio Costa for their invaluable help and advice; to my technician, Mrs. Jennie Johnson, for her excellent work and to Drs. A. Hoffer, B. Melander of K.A.B.I., and S. Gimpel of Sandoz for generous gifts of adrenochrome, adrenolutin and lysergic acid and its brom derivative, respectively.

Antibody Formation by Isolated Spleen Cells transferred to Recipients in Absence of Homotransplantation Reaction

It is generally agreed that the internal environment in new-born animals is not favourable for antibody formation to occur, as has been postulated by Dixon[1,2]. It has, however, been demonstrated in our laboratory[3-5] that new-born animals are more suitable recipients for transferred cells producing antibodies—during the period when they are not capable of their own active antibody synthesis[6]—than X-irradiated adult animals. We suppose that the homotransplantation reaction is the main factor limiting antibody formation by cells transferred to young animals[7]. Simonsen[8] has shown that spleen cells of adult hens are tolerated if transferred to chicken embryos three days before hatching. We assumed, therefore, that by using the chicken embryo as recipient it will be possible to obtain fully developed formation of antibodies to bacterial antigens and also a positive primary response to a protein antigen. According to Dixon's assumption, this should, on the other hand, lead to a further decrease in the intensity of antibody formation in embryos.

Normal White Leghorns weighing 1·5–2 kgm. were used as donors of spleen cells, which were isolated as described in a previous report[4]. Spleen cells mixed with antigen *in vitro* were transferred either by intraperitoneal route to chickens 2 days after hatching or into the chorioallantoic vein of 18-day-old chicken embryos. 6×10^7 cells were transferred to chickens and 5×10^7 cells to embryos. The number of cells was determined by counting in a Bürker's chamber. A heat-inactivated suspension of *Brucella suis* (in a ratio of two bacterial cells to one spleen cell) and bovine serum albumin (1 mgm. per embryo or chicken) were used. Cells were transferred simultaneously with antigen; to controls, animal cells only or antigens only were given. Blood for determination of antibody titres was taken at different time-intervals according to the antigen used. This was usually 10, 14, 20 and 28 days after transfer in the case of bovine serum albumin and 5, 7, 9, 12, 16 and 24 days after transfer when using *Brucella suis*. Antibodies were determined by agglutination of the suspension of *Brucella suis* or tanned sheep erythrocytes sensitized by bovine serum albumin. 73 per cent of chickens hatched from the embryos to which spleen cells had previously been transferred died within 15 days after transfer with typical symptoms of the runt disease. The decrease of blood hæmoglobin in chickens before death was even lower than 10 per cent. Symptoms of the runt disease served at the same time as indicator of a successful cell transfer.

The experiments were performed as follows. In the first group, cells with the *Brucella* antigen were transferred to two-day-old chickens and 18-day-old embryos. The antibody formation occurred in all the 20 transfers to chickens, with a maximum titre 1 : 128 (M = 1 : 32). Out of 17 transfers to embryos there was a positive antibody response in all experimental chickens, with a maximum titre 1 : 130,000 (M = 1 : 4,096). The transfer of cells only (13 embryos, 7 chickens) or antigens only (12 embryos, 9 chickens) was always negative during the critical period, that is, up to the fifteenth day of life. This group of experiments is illustrated in Fig. 1. In the second group of experiments bovine serum albumin was used as antigen under the same experimental conditions. In none of the transfers to

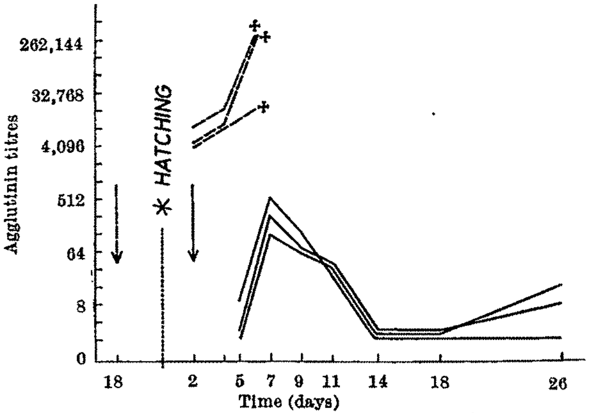

Fig. 1. Antibody formation following transfer of cells with *Brucella* antigen to embryos and chickens. Full line, transfer to 2-day-old chickens; interrupted line, transfer to 18-day-old embryos. A cross indicates that animals died with symptoms of the runt disease

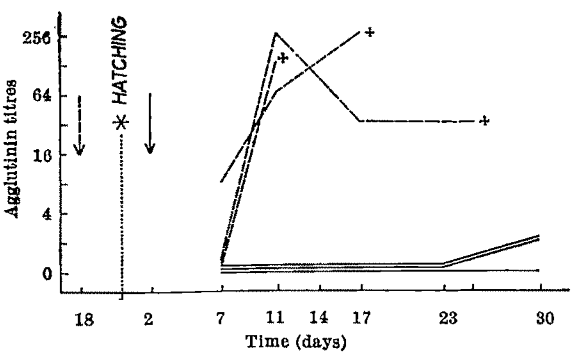

Fig. 2. Antibody formation following transfer of cells with protein antigen (bovine serum albumin) to embryos and chickens. Full line, transfer to 2-day-old chickens; interrupted line, transfer to 18-day-old embryos. A cross indicates that animals died with symptoms of the runt disease

chickens (26 transfers of cells with bovine serum albumin, 21 transfers of bovine serum albumin only and 18 transfers of cells only) was it possible to demonstrate any antibody formation. A positive response was, however, obtained in transfers to embryos during the critical period, that is, within 15 days; there were 21 positive responses out of 27 transfers performed, with a maximum titre 1 : 512 ($M = 1 : 64$). No antibody formation could be demonstrated in 18 control experiments in which cells only and in 27 control experiments in which bovine serum albumin only were transferred. This second group of experiments is illustrated in Fig. 2.

The results of our experiments primarily indicate that the immaturity of the recipient does not affect the response of the transferred cells, as has been postulated by Dixon and his co-workers, but that the limiting factor is the homotransplantation reaction. When the transplantation reaction is eliminated by using transfer to embryos, the transferred cells form antibodies in large titres. Using this experimental model in which the function of the transferred cells is not disturbed by the reaction of the recipient, we succeeded in obtaining antibody formation even to protein antigens, that is, in evoking a typical primary response.

Presence of Antigen—a Factor determining the Duration of Antibody Formation by Transferred Cells

In experiments on antibody formation by isolated spleen cells after transfer to new-born rabbits[1] and newly hatched chicks and embryos[2] it has been found that the ability to form antibodies is limited in time, this being due to the reaction of the recipient to the transferred cells[3]. If spleen cells only were transferred to new-born rabbits and then antigen administered at different time intervals, it was demonstrated that only during the first 4 days after cell injection did the administered antigen regularly evoke antibody formation. Injection of antigen on the fifth day gave positive results only occasionally, and administration of antigen after the seventh day did not result in production of antibodies by transferred cells.

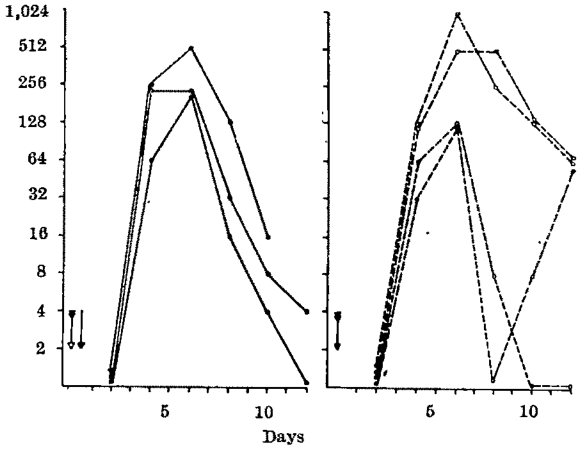

Fig. 1. Transfer of spleen cells intraperitoneally to one-day old ducklings. Left, 10⁸ spleen cells (in 1 ml.) from normal adult donor mixed with antigen *Brucella suis in vitro*; right, 50 × 10⁶ spleen cells (in 1 ml.) from adult donor immunized with three doses of antigen *B. suis*

In further experiments one-day-old ducklings were used as recipients in order to find out whether the reaction of the recipient to the transferred cells is the only factor determining the period during which they are capable of producing antibodies. It is known[4] that at that period of life these animals are tolerant to transferred cells. Ducklings injected with bacterial antigen (*Brucella suis*) commence the formation of antibodies after the twelfth to fifteenth day of life.

Spleen cells from immunized adult duck or spleen cells from non-immunized donor mixed with antigen *in vitro* were transferred to one-day-old ducklings. In both cases (Fig. 1) the injected cells produced antibodies during a short period after transfer. Since the cells were injected into animals in which the decline in antibody formation cannot be ascribed to

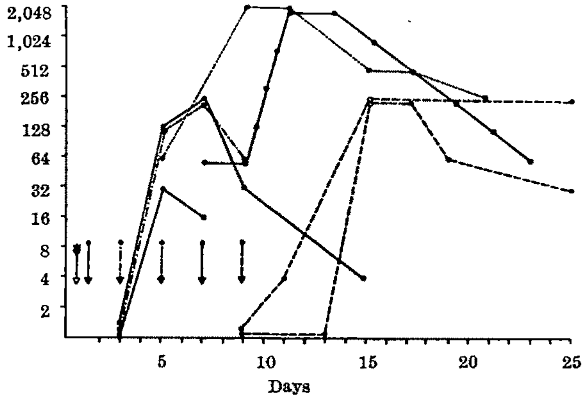

Fig. 2. Transfer of adult spleen cells only to one-day-old ducklings. Individual groups were injected with antigen *B. suis* immediately or 2, 4, 6 or 8 days after administration of cells

the homotransplantation reaction, we tried to find another explanation. It was assumed that the transferred cells differentiate in the recipient's body and that antibody production is determined by the life-span of those differentiated cells incapable of further proliferation ; another possible explanation was that the antigen was used up during the formation of antibodies and that the transferred cells, though capable of antibody response, do not produce antibodies because of the absence of antigen.

After the transfer of cells, antigen was injected into individual groups of ducklings at different time-intervals ; one of the results is given in Fig. 2. The formation of antibodies evoked by antigen administration (at the period in which active antibody response to antigen is not yet developed in ducklings) indicates the presence of transferred cells capable of reacting to antigen even at that time when the spleen cells from immunized donor or cells mixed with antigen *in vitro* and transferred to ducklings cease to produce antibodies (Fig. 1). The decrease in antibody formation by transferred cells may be explained by the absence of antigen.

These findings show that transfers to non-reactive recipients may be used for determining the importance of the presence of antigen for antibody formation.

Further details will be published elsewhere[5].

Antiviral Activity of Lysozyme

The biological significance of lysozyme is not yet fully established. Its properties suggest that it has a role in immunism against bacterial infections. Lysozyme also seems to show antiviral activity. Previous observations support this possibility.

Macfarlane Burnet[1] observed that nasal mucus inactivates poliomyelitis virus of any type *in vitro* ; on the other hand, however, pure lysozyme did not. Caselli and Schumacher[2] demonstrated antagonism between lysozyme and electronegative viruses. Orzalesi[3] obtained very satisfactory results in the treatment of herpetic keratitis with lysozyme and observed the inactivation of herpetic virus by lysozyme *in vitro*.

Pursuing this line of research on the relationship between lysozyme and viruses, some interesting results have been obtained in our laboratories. *In vitro*, we observed that lysozyme precipitated bacteriophage viruses and *in vivo*, in guinea pigs experimentally infected with aphthosis virus, we obtained good results with the administration of lysozyme in 80 per cent of the animals.

Callerio observed a constant reduction of serum lysozyme in poliomyelitis patients, but some therapeutic trials with this enzyme were confusing. A communication from A. D. Ronchese of Nice, stating that he has obtained recovery in four cases of herpes zoster by oral treatment with lysozyme, induced us to extend our clinical observations[4].

Many Italian dermatologists have tried the administration of lysozyme by parenteral route in several virus diseases.

Lysozyme, in adequate dosage, has been shown to be effective in the treatment of viral infections such as herpes simplex, herpes zoster, warts, condylomata acuminata, aphthosis and vaccinia. These results need further confirmation, however, so that the antiviral spectrum of lysozyme as well as its real value in the therapy of viral diseases may be definitely established.

BACTERIOLOGY

Decomposition of Anionic Surface-Active Agents by Soil Bacteria

In a review of water pollution problems created by the persistence of anionic surface-active compounds in sewage and sewage effluents, Southgate[1] has pointed out that sodium alkyl sulphates are more susceptible to biological degradation than the alkyl benzene sulphonates which are active constituents of some domestic detergents. This resistance of the alkyl benzene sulphonates of commerce to biological oxidation has been attributed to the branched carbon atom chains of their alkyl groups. On the other hand, the alkyl sulphates in common use have, fortuitously, alkyl groups with straighter carbon chains more readily oxidized by micro-organisms[2]. Although some bacteria attacking anionic compounds have been reported[3], there is very little published information on bacteria responsible for breaking down even the more easily decomposable compounds.

This communication records the isolation of a bacterium able to use both primary and secondary alkyl sulphates as carbon sources. This organism developed from a sample of allotment soil which had been incubated at 25° C. for two weeks with water containing a trace of 'Teepol 530', a secondary alkyl sulphate. After further cultivation in a buffered mineral salt solution ($(NH_4)_2SO_4$, 0·5 gm. ; K_2HPO_4, 6·5 gm. ; KH_2PO_4, 3·5 gm. ; $CaCl_2$, 0·05 gm. ; $MgSO_4.7H_2O$, 0·05 gm. ; NaCl, 1·0 gm. ; distilled water, 1 litre ; *p*H 7·0) with 0·1 ml. 'Teepol' per litre, the organism was isolated from plates of the same medium solidified with 1·5 per cent agar.

Cells of this isolate are aerobic, Gram-negative rods, $0·6–0·7\mu \times 0·6–2·2\mu$, with polar flagellation. Only in very young cultures are all the cells vigorously motile. On nutrient agar prepared from fresh ox heart extract and peptone, a trace of greenish fluorescent pigment appeared in the medium ; but little or no such pigment formed in media made from commercial meat or yeast extracts. Acid but no gas was formed from glucose, fructose, mannose, galactose, xylose, arabinose, sucrose, maltose, lactose, glycerol and mannitol. Starch, cellulose, salicin and *Ricinus* seed oil were not attacked. In the test of Shewan *et al.*[4], growth was inhibited by streptomycin, chloramphenicol and terramycin but not by penicillin or the vibriostatic agent 0/129. For these reasons the organism has been referred to the genus *Pseudomonas*; but the species has not yet been identified or named. It does not correspond well with any previously described soil or freshwater species.

The effect of the growth of this organism on surface tension in mineral salt solution containing different concentrations of 'Teepol 530' has been examined (Table 1). Surface tension measurements were made with a du Noüy tensiometer at 20° C.

Table 1. CHANGES IN SURFACE TENSION OF MEDIA CONTAINING DIFFERENT CONCENTRATIONS OF 'TEEPOL 530' DURING TWO DVYS OF INCUBATION

Conc. 'Teepol' ml./l. medium	Surface tension (dynes/cm.)					Increase (per cent)
	Initial		After 2 days		Increase	
	Duplicate samples	Mean	Duplicate samples	Mean		
0·1	36·2 35·3	35·8	68·3 68·1	68·2	32·4	90·5
0·2	35·7 35·2	35·5	66·7 67·3	67·0	31·5	88·7
0·5	32·9 32·4	32·7	53·4 53·2	53·3	20·6	63·0
1·0	31·5 31·4	31·5	42·8 41·6	42·2	10·7	34·0
2·0	31·3 31·3	31·3	33·2 33·0	33·1	1·8	5·8

After two days cultures originally containing 0·5 ml./l. 'Teepol' or less had almost no tendency to foam on shaking. Foam stability was also greatly decreased in cultures with higher concentrations of 'Teepol' even though increases in surface tension had been only slight during the period of test. In a second experiment in which 500 ml. portions of the same basal medium containing 2 ml. 'Teepol' per litre were incubated for 16 days, foam was also very unstable after 3 days but did not become noticeably more unstable thereafter. Though growth, as judged by measurements of turbidity, ceased between the fourth and sixth days, surface tension rose steadily from 31·1 dynes/cm. at the start of the experiment to a final, but still low, value of 47·0 dynes/cm. on the sixteenth day. The bacterium could grow well in media containing, as sole carbon sources, primary sodium alkyl sulphates with alkyl groups of 10–18 carbon atoms. Also utilized were all the five 'Empilan' alkylolamide detergent additives which were tested: these were Types *AL*, *CM*, *LDE*, *LP*2 and 303 (Marchon Products, Ltd.). However, tetrapropylene benzene sulphonate, an active constituent of some commercial detergents, was not attacked. Indeed, though many soil micro-organisms were observed to tolerate the presence of this persistent compound, none capable of utilizing it could be isolated.

Malachite Green - reducing Enzyme in *Mycobacteria*

In experiments with the lipids of different *Mycobacteria* we found that the acetone solution of lipids becomes green in colour as a result of certain oxidizing agents. A more precise examination revealed that such a change in colour occurred in the lipid solutions of only those bacteria which were grown in media containing malachite green.

Four saprophytic (*M. butyricum*, *M. friburgensis*, *M. rabinowitsch*, *M. smegmatis*) and two parasitic (*H*37*Rv.*, Ravenel) strains were grown in normal Sauton culture medium and in Sauton culture medium containing malachite green (10 μgm./ml.) respectively.

After incubation for six days the saprophytic cultures were filtered by means of paper filters, washed five times with distilled water, and dried at 37° C. over calcium chloride. 250 mgm. dry weight of the bacteria was suspended in 2·5 ml. acetone and left at room temperature for 10 min. Then 250 mgm. of lead dioxide was added, and the tubes were shaken, and centrifuged. The supernatant contained lipids or, in the case of a medium containing malachite green, it contained this dye. The parasitic strains were incubated for 50 days, sterilized in the autoclave, and then treated in the same manner as the saprophytes. In order to identify the dye and to measure its quantity, the absorption curves of the solutions were determined with the use of a Beckman spectrophotometer at 340–700 mμ wave-lengths.

It was found that the maximal absorption values for the solutions of the bacteria grown in a medium containing malachite green were at 420 and 630 mμ. In contrast, the solutions of the bacteria grown in normal Sauton medium showed no absorption at the wave-lengths studied. The maximal absorption values for the acetone solutions (2 μgm. per ml.) of the malachite green oxalate used were found to be at 430 and 630 mμ. The relative intensity of the absorptional maximal values was 630 > 430 or in the case of bacterial lipid solutions 630 > 420.

On the basis of the results of spectrophotometric examination it seems likely that malachite green is reduced by the growing bacteria, and the leuco-compound remains absorbed in the bacterial bodies. By means of lipolysing agents, it can be extracted together with the bacterial lipids, and then it becomes again a coloured compound after oxidation. The amount of the dye reduced is great, as shown by the fact that ten times as much malachite green (20 μgm./ml.) as the quantity used in normal media (for example, Sula medium) can be reduced by growing mycobacterial strains.

In order to establish the *p*H optimal for reduction, acetone-dry preparations made according to Edson's and Hunter's method[1], saprophytic *Mycobacteria* grown in Sauton medium for 5 days, were used. Such preparations can be stored for indefinite periods in refrigerators without loss of potency.

In order to measure the amount of the dye reduced at various *p*H-levels under the same periods of time, 10-mgm. acetone-dry preparations were placed in dry Wassermann tubes. After the addition of 1 ml. of universal buffer solution and 10 μgm. of malachite green (dissolved in 0·2 ml. water) the tubes were incubated in a water-bath of 37° C. for 30 min. Then, the tubes containing the suspensions were shaken in the presence of 2 ml. of acetoacetic ester for 5 min. and centrifuged. The upper aqueous layer was

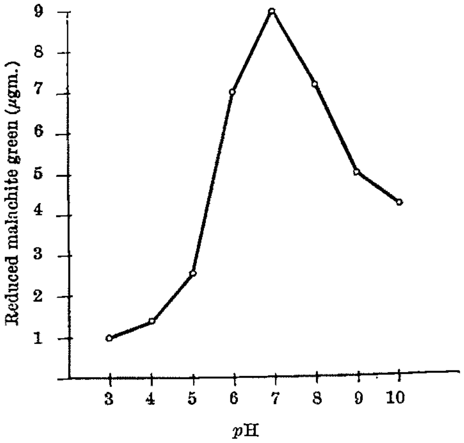

Fig. 1. Effect of *p*H on the reduction of malachite green by acetone-dry powder of *M. friburgensis*. Incubation, 30 min. at 37° C., in universal buffer solution

removed. To the acetoacetic ester malachite green solution 100 mgm. of anhydrous magnesium sulphate was added, the tubes were shaken, centrifuged, and the pure solution obtained was examined with a spectrophotometer at 630 mμ to determine the amount of malachite green.

The *p*H optimal for reduction was found to be 7·0 (Fig. 1).

Using *p*H 7·0 buffer solution the preparations were entirely inactivated by incubation at 60° C. for 30 min.

In addition, inactivation of the preparations could be obtained by *p*-chlormercuric benzoic acid, monoiodoacetic acid and hydrogen peroxide. Cystein or glutathione was found to reactivate the inactivated preparations.

The enzyme responsible for the reaction could not be extracted from the bacteria by the usual methods. It is suggested, therefore, that this enzyme is not identical with the reported reducing enzymes of the *Mycobacteria*[2-5].

Further observations will be reported in due course.

Selection of Bacterial Mutants of Increased Sensitivity to 'Aminopterin'

Some understanding of the cellular responses which modify the effectiveness of growth-inhibitors can be gained by the study of closely related populations of microbial or mammalian cells differing in degree of sensitivity to a drug. Microbial cell lines resistant to antibiotics and antimetabolites can be developed readily by the selection of cells capable of surviving in the presence of increasing concentrations of such drugs[1]. Similar selection of drug-resistant neoplastic cells has been accomplished both *in vivo*[2] and *in vitro*[3]. Occasionally the development of resistance to one drug is accompanied by changes which confer an increased sensitivity to a different agent, a finding applicable to both microbial[4] and neoplastic cells[2,5]. The physiological mechanisms and metabolic systems associated with any increased effectiveness of drugs are of vital concern, but have received little attention because of the technical difficulty of directing the selection towards an increased, rather than decreased, responsiveness to a drug if that drug is used as the selecting agent. This communication concerns the reproducible selection in the absence of the drug of bacterial mutants of increased sensitivity to a folic acid antagonist ('Aminopterin').

Pediococcus cerevisiae, strain 8081, has been widely used for the assay of reduced derivatives of pteroylglutamic acid (folic acid) such as 5-formyl-tetrahydropteroylglutamic acid, which have folinic acid activity[6]. This organism can grow, however, in the absence of folinic acid if very high concentrations of pteroylglutamic acid are provided in the medium[7]. Pteroylglutamic acid was used as a selecting agent for strains which could grow well in media supplying progressively smaller amounts of this form of the vitamin. Over the course of eleven transfers, the concentration of pteroylglutamic acid necessary for growth was reduced from 2,000 mμgm. to 10 mμgm. per ml. of medium. The response of the selected strain (8081/*S*) to 5-formyl-tetrahydro-pteroylglutamic acid was identical to that of the parent organism (Table 1). Thus, it was possible to compare the sensitivity of these strains to 'Aminopterin' in the absence of the selecting agent by using a medium containing 5-formyl-tetrahydro-pteroylglutamic acid. The selection of strains capable of growing in medium containing 10 mμgm. of pteroylglutamic acid per ml. was repeated twice. In each case these cell lines were found to be 60–100 times more sensitive to 'Aminopterin' than the parent strain (Table 1). The characteristics of increased sensitivity to 'Aminopterin' and ability to grow promptly at low concentrations of pteroyl-

Table 1. Comparison of the Response of *Pediococcus cerevisiae* 8081 and a Selected Mutant (8081/*S*) to Folic Acid, Folinic Acid and 'Aminopterin'

	1,000	17	30

* The compounds were added to a medium used for the microbial assay of folinic acid activity (refs. 6 and 7). The concentration required for 50 per cent growth was determined from a graph of the complete curves for growth and inhibition.

† The inhibition of growth by 'Aminopterin' was measured in liquid and solid medium which contained 1·0 mμgm. per ml. of the active isomer of 5-formyl-tetrahydro-pteroylglutamic acid.

‡ The same medium with the addition of 1 per cent agar was seeded with each organism and poured into flat 'Pyrex' dishes. Solutions of the compounds were pipetted on to filter paper disks of ½ in. diameter which were placed on the surface of the solid medium. Each figure represents the average diameter of two zones, each measured along two 90° axes.

glutamic acid were retained after fifteen passages in the absence of the selecting agent.

In this case, in which the metabolite, pteroylglutamic acid, exerted a selective pressure in the direction of its more effective utilization, the selection was consistently accompanied by an increased sensitivity to a corresponding antimetabolite, 4-amino-pteroylglutamic acid. The ability to use a metabolite as a selecting agent apparently requires that the organism should have the potentiality of increasing its efficiency for the utilization of the metabolite. In any instance in which such a selection can be accomplished, this approach appears to be useful for the study of an altered response to corresponding antimetabolites. The requirement of cultures of leukæmic cells for 5,000-fold higher concentrations of folic acid than folinic acid[8] indicates that similar manipulation of the sensitivity of such neoplastic cells may be feasible. An equivalent increase in the sensitivity of strain 8081/*S* has been observed with respect to both 4-amino-pteroylglutamic acid and 4-amino-10-methylpteroylglutamic acid ('Methotrexate'); related compounds can be compared with respect to cross-sensitivity. Also, it will be of interest to study any characteristics which can be associated with the increased sensitivity of strain 8081/*S* to 'Aminopterin' in relation to the development of resistance by cells of this strain selected by this drug.

The mutant of *Pediococcus cerevisiae* (strain 8081/*S*) selected by pteroylglutamic acid now resembles *S. faecalis* and *L. casei* with respect to their characteristic growth requirement for either folic acid or folinic acid and their high degree of sensitivity to 'Aminopterin' and 'Methotrexate'. The nutritional selective pressure used in these studies may be a counterpart of the natural selection which occurred at some time during the evolutionary development of organisms such as *S. faecalis* and *L. casei*.

This investigation was supported in part by a research grant (*CY* 2906) from the National Cancer Institute of the U.S. Public Health Service. The capable assistance of Mr. Robert J. Leonard is gratefully acknowledged.

AGRICULTURAL SCIENCE

Varietal Resistance to Spray Damage in Barley

IN experiments designed to control insect pests in the cereal nursery at the Welsh Plant Breeding Station it was noticed that there was considerable damage on barley plants after spraying with a proprietary insecticide containing DDT, which had been applied according to the manufacturers' instructions for field spraying. Certain plants suffered severe chlorosis; the sprayed leaves turned yellow and failed to recover, while succeeding leaves were green and appeared to be unharmed although productivity was severely reduced. Spraying at the early seedling stage and under unfavourable environmental conditions caused wilting and even death of the plant.

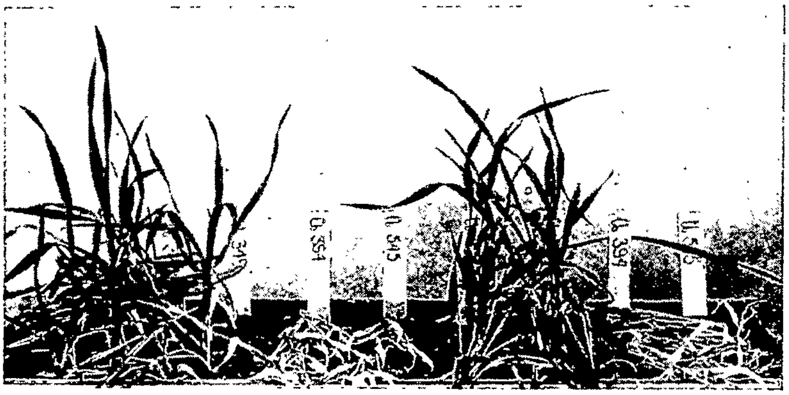

Fig. 1. Typical reaction of four barley varieties to spray damage. *R*, resistant; *S*, susceptible

Further investigation in both greenhouse and field nursery showed that the damage was confined to certain varieties. Fig. 1 shows the clear-cut reactions of typical resistant and susceptible varieties under greenhouse conditions. Twenty-six commercial varieties of barley are classified in Table 1 according to a distinct reaction of resistance or susceptibility to spray damage.

Table 1. REACTION OF SOME BARLEY VARIETIES TO SPRAY DAMAGE

Resistant	Resistant	Susceptible	Susceptible
Balder	Maythorpe	*Atlas	Praecox
Carlsberg II	Prefect	Domen	Piroline
Earl	Proctor	Freja	Primus
*Goldberg	Provost	Frisia	Rika
*Gull	Spratt Archer	*Haidd Hen Enlli	Vinesco
Ingrid	Ymer	*Hen Gymro	Wisa
Kenia		Herta	

* 'Land' variety or selection

Preliminary evidence that this reaction is genetically controlled was obtained by studying the pedigree of the above varieties. For example, it can be seen from Table 1 that Provost (resistant) was derived from a cross between Kenia and Spratt Archer, both of which, it will be noted, are resistant, while Prefect is a resistant segregate from the susceptible form Praecox and the resistant Spratt Archer. Confirmatory evidence of the genetic mechanism involved was obtained from the reaction of F_1 and F_2 plants from crosses of resistant and susceptible parent plants. Progeny from resistant × resistant crosses were all resistant to spray damage, while susceptible × susceptible crosses gave only susceptible progenies.

Table 2. REACTION OF F_1 PLANTS AND F_2 SEGREGATES FROM RESISTANT × SUSCEPTIBLE CROSSES

Parents	Generation	Expected or observed	No. of plants	
			Resistant	Susceptible
Resistant × Susceptible	F_1	Observed	—	72
	F_2	Observed Expected (3 : 1 ratio)	83 71·5	203 214·5

$\chi^2 = 2{\cdot}25$. $P = 0{\cdot}50$–$0{\cdot}10$.

Inheritance studies on resistant × susceptible crosses gave the segregation in Table 2.

All the available evidence, therefore, strongly indicates that varietal differences are controlled by a single major gene with susceptibility dominant to resistance.

Reference to Table 1 emphasizes that the alleles are randomly distributed among the commercial varieties of barley; thus there is no suggestion that this gene has had any selective influence in previous plant-breeding programmes. Furthermore, studies to date have not revealed any gross morphological features associated with this reaction. It is interesting to note the reaction of the five 'land' varieties and their derivatives; for example, Gull, the 'land' variety from Sweden, is resistant, while recently bred varieties from the same country, namely, Herta and Rika, are susceptible. Atlas, a selection from Coast which is believed to have been introduced into North America by the Spanish settlers, and Hen Gymro from Wales, are both susceptible. Thus there does not seem to have been any advantage or disadvantage associated with this gene during the evolution of the cultivated barleys. Since the use of insecticides on agricultural crops is of recent origin, it follows that this factor, which does not appear to have any other expression, has not hitherto been selected by plant breeders.

A knowledge of varietal reaction of this nature is important to research workers developing new insecticides as well as plant breeders. It will be a simple matter from the plant breeding point of view to avoid developing new varieties of barley which are susceptible to this damage, on account of the fairly large number of well-adapted resistant types already available. Further work is in progress to determine the nature of the chemical constituent responsible for the damage and the full genetic and physiological action involved.

Fuller details of this investigation will be published elsewhere.

Rumination in Sheep caused by Injection of Adrenaline

THE injection of adrenaline into sheep anæsthetized with chloralose causes a rapid secretion of parotid saliva[1]. This is a reflex effect and appears to be due largely to stimulation of receptors in the forestomach. Parotid secretion is also increased by mechanical stimulation of the forestomach and in conscious sheep this stimulation may cause rumination[2]. Thus it seemed of interest to find whether adrenaline would cause the conscious sheep to ruminate, and observations on this subject are summarized here.

Six sheep trained for the experiments were each fitted with a rumen cannula and a cannula in one parotid duct. Contractions of the reticulum were recorded with a water manometer connected to a balloon placed in the organ and the flow of parotid saliva was recorded with a Throp drop counter. Adrenaline ('Adrenalin'; Parke, Davis) was injected during 5 sec. through a catheter inserted into a jugular vein.

A period of rumination followed adrenaline injection in all the sheep. An example is shown in Fig. 1, in which the onset of rumination is signalled by a triphasic contraction of the reticulum of lower amplitude than previous contractions and is accompanied by an increase in parotid secretion.

The threshold dose of adrenaline was 0·2–0·7 μgm./kgm. body-weight and there was a delay of 40–155 sec. between the start of the injection and the first regurgitation. Rumination was preceded by a number of changes, including alert movements of the head, sneezing, belching, urination or an increase in parotid secretion. Removal of the rumen contents and of the reticulum balloon made little or no difference to the threshold dose. In such sheep 'rumination' consisted of triphasic reticulum contractions and regurgitation of fluid. Larger doses of adrenaline (2–20 μgm./kgm.) caused rumination in most trials, although the initial triphasic reticulum contractions were often depressed. The latency of the response varied from 24 to 137 sec. Slow injection of adrenaline in doses of 1–20 μgm./kgm. during 2 min. failed to cause rumination. Noradrenaline ('Levophed'; Bayer) caused rumination in 3 of the 4 sheep tested at threshold doses of 1·5, 2·5 and 5·0 μgm. noradrenaline base/kgm. Injections of saline alone had no effect.

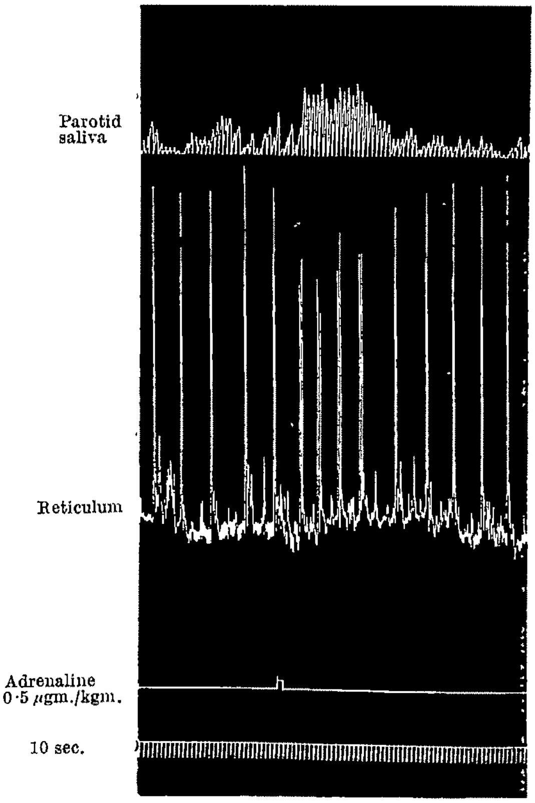

Fig. 1. Rumination caused by intravenous injection of adrenaline. Records from above downwards: parotid secretion (counter returned to base-line at 10-sec. intervals), reticulum contractions, signal, 10-sec. time marker

It is possible that adrenaline causes rumination by the same reflex mechanism that is concerned in the stimulation of parotid secretion in anæsthetized sheep. It is unlikely that the adrenaline acts on forestomach mechanoreceptors indirectly by causing muscular contraction, for no abnormal contraction was recorded from the reticulum and its action on the stomach of conscious sheep is known to be inhibitory[3]. The threshold dose of adrenaline, 0·2–0·7 μgm./kgm., corresponds to mean plasma adrenaline concentrations of 4–14 μgm./l., assuming 50 ml. plasma/kgm. body-weight. Although these concentrations are similar to those of 2·44–12·6 μgm./l. found by Weil-Malherbe and Bone[4] for bovine plasma, the blood analysed by these authors was collected at slaughter when adrenaline-levels might well be elevated abnormally. Moreover, to cause rumination the adrenaline had to be injected rapidly, so that the actual plasma concentration will transiently have exceeded the mean plasma concentration. It must be emphasized, therefore, that the present observations do not indicate that adrenaline release plays a part in the initiation of rumination in the normal animal. On the other hand, Loewenstein[5] has shown that both the application of adrenaline or noradrenaline to frog skin and stimulation of the sympathetic innervation cause activity in cutaneous touch receptors, and suggested that sensitization of such receptors through the sympathetic nervous system might normally occur in intact animals. The receptors of the sheep's forestomach may also be sensitized in this way.

Inducing Chlorophyll Formation in Albino Citrus Seedlings

ALBINO seedlings, that is, seedlings lacking chlorophyll, are observed in varying degrees in citrus seed beds according to variety. In sweet lime 30 per cent or more of the young seedlings may be albino. This lack of chlorophyll is attributed by some botanists to infection with an unknown disease. Treating citrus seeds before planting with mercuric disinfectants such as 'Ceresan'[1] and 'Agrosan'[2] resulted in the production of seedlings which with the former were nearly all and the latter all green. In this study albino seedlings were grafted on to green seedlings to see whether chlorophyll formation would be blocked in the latter as a result of possible transmission of the disease which is suspected to cause albinism or whether chlorophyll formation could be induced in albino seedlings.

Sweet lime seeds were planted in a mixture of 1 part sand to 3 parts loam in an incubator at 28–30° C. and 80–90 per cent humidity. Because the sweet lime is polyembryonic, more than one seedling were produced per seed. In many instances both albino and green seedlings were produced from the same seed, and thus were very close to each other, making grafting in these young seedlings possible. Grafting was done by the approach method in which a small slice of stem of both the albino and the green seedlings were cut and the cut surfaces brought together and tied until they united. The cuts were made as high as possible to leave a few buds on the stem of each seedling. Grafting was done as soon as the plants were about 5 cm. high. Too long a delay must be avoided, for the albino seedlings usually die after using up the food reserve in the embryos from which they develop.

Out of 30 grafts 11 succeeded. The tops of the albino seedlings above the grafting union died. None of the green seedlings in these successful grafts showed any chlorophyll irregularities as a result of grafting an albino seedling (which is supposedly diseased) on it.

A year later, leaves of the originally green seedlings were still green and the stems of such seedlings at the grafting union-level was about 1 cm. in diameter. The stems of the albino seedlings reached about the same diameter but no shoots grew on them, although they had a few buds on each. These buds were forced to grow by ringing the stems of the originally green seedlings immediately above the grafting union. All shoots produced in this way had only green leaves and seemed normal. These shoots remained green after separation of the two seedlings from each other.

These findings indicate that the causal factor of albinism was not transmitted across the grafting union, or if transmitted was unable to induce albinism in the originally green seedlings. The results also show that the effect of this causal factor is temporary and limited to the early stages of seedling growth. Cutting off the top of the originally green seedlings to the grafting union or separation of the originally albino from the originally green seedling (top and root) did not cause any disturbance in chlorophyll formation in the green shoots obtained from originally albino seedlings. This result seems to contradict the view that albinism is due to recessive genes, as was claimed for the Szinkom mandarin[3].

Antigenic Stimulus of Exsheathing Fluid in Self-Cure of Sheep infested with *Haemonchus contortus*

IT has been reported that the second ecdysis of *Ascaris lumbricoides* is probably important in the stimulation of protective immunity in guinea pigs[1–2]. Up to 4 days after the administration of ova, developing larvæ appear to be of little importance in stimulating immunity and are themselves unaffected by immune processes. Using the Forssman antibody as a natural marker, it was demonstrated that a large release of antibody does not occur until 4–5 days after the administration of ova[3]. This period coincides with the second ecdysis, and it was suggested that this process is important in stimulating immunity by the liberation of antigens.

Two stages are involved in the second ecdysis of nematode larvæ in sheep[4]. Larvæ are activated by a dialysable factor or factors in the alimentary tract and then secrete exsheathing fluid from a region near the base of the œsophagus. Exsheathing fluid acts on a circumscribed region of the cuticle which eventually fractures and enables the larva to escape. Exsheathing fluid was collected as a dilute solution[5] which was found to contain other antigenic substances also released by the larvæ at the time of the second ecdysis.

The self-cure reaction is produced in hypersensitive infested sheep by the intake of infective larvæ. The reaction is accompanied by a rise in circulating antibodies and a transitory rise in blood histamine[6].

The serological reaction which occurs at the time of self-cure has now been examined by the Ouchterlony agar-diffusion precipitin technique. It was found that four lines developed when heated *Haemonchus contortus* antigen[7] was tested with a serum obtained when self-cure took place after the administration of *H. contortus* infective larvæ to an infested sheep. The antigenic components responsible for the main reactions were identified by the cross-reactions which occurred between the serum, the heated antigen, exsheathing fluid solution from *H. contortus* infective larvæ and metabolic products. The metabolic products were collected by harvesting a saline solution in which exsheathed *H. contortus* infective larvæ had been kept with added antibiotics for 24 hr. at room temperature. The line which appeared closest to the antigen well was produced by tissue antigens, the second line also by tissue antigens together with a component due to exsheathing fluid solution, the third line mainly by exsheathing fluid solution but partly by metabolic products, and the fourth line, closest to the serum well, was produced primarily by metabolic products. It is not surprising that there was some overlapping between these lines, because exsheathing fluid solution was found to contain a number of antigenic substances, some of which are also present in metabolic products.

The agar-diffusion precipitin reactions developed with serum collected within a week of the administration of larvæ, and the lines produced by metabolic products and particularly by exsheathing fluid solution were the most pronounced. By slaughtering infested sheep at intervals after the administration of infective larvæ it was found that, at the time of the self-cure reaction, when much of the existing adult *H. contortus* infestation was located in the small intestine and was in a state of disintegration, fourth-stage larvæ of varied size as well as third-stage larvæ were present in the abomasum. It seems probable, therefore, that the self-cure reaction is initiated by an antigenic stimulus arising from the third ecdysis. Although there is as yet no evidence that the third ecdysis produces exsheathing fluid, the serological evidence indicated that similar antigens were released as in the second ecdysis.

BIOLOGY

Occurrence of *Pyrosoma* on the Sea-Floor 160 Metres Deep

Pyrosoma species are commonly encountered as surface or midwater planktonic organisms. Among photographs taken of the sea-floor of Cook Strait, New Zealand, two exposures show what are undoubtedly tunicates, almost certainly *Pyrosoma atlanticum atlanticum* Peron, resting on or swimming just above the bottom at a depth of 160–170 m.

The depth is in itself not unusual—Thompson[1] reports finding this species off Australia in greatest numbers between 250 and 500 m.—but we are not aware of previous records of *Pyrosoma* so close to the bottom. It may be that our records indicate no more than a normal range of depth distribution. On the other hand, since they were made at 1022 and 1505 hr. they may indicate a daytime preference for deeper water; Thompson does not indicate the times at which his observations were made. It is possible that the animals are actively seeking the bottom to avoid other unfavourable surface conditions.

The shadows cast by a camera flash (New Zealand Oceanographic Institute Station *C*.122, 18.5.58; 162 m.; lat. 41° 19′ 04″ S.; long. 174° 32′ 36″ E.) show that the *Pyrosoma* are within inches of the bottom, and some are certainly resting on it. They are firm and regular in shape, indicating that they are not dead and decomposing. Shadows and blurred shapes in another photograph (New Zealand Oceanographic Institute Station, *C*.119, 17.5.58, depth 169 m.; lat. 41° 18′ 45″ S.; long. 174° 32′ 30″ E.) indicate specimens actively swimming just above the sea-floor.

At this time of the year (May 1958), *Pyrosoma* were extremely common in the Cook Strait region. Mr. N. M. Ridgway, of this Institute, noted that colonies up to 15 in. long were frequently seen swimming past the ship at night during May 15–19, and were occasionally entangled in the wires used for current measurements. On May 16, Mr. F. C. Abernethy, engineer of the trawler *Thomas Currel*, recorded large numbers off Cape Campbell at a position (lat. 41° 54′ 36″ S.; long. 174° 11′ 55″ E.) approximately 40 miles from Stations *C*.119 and *C*.122, and noted the surface temperature as 54° F. (12·2° C.).

Prof. H. B. Fell, of Victoria University of Wellington, has brought to our notice a record of another observation by Mr. Abernethy, some time shortly before October 20, 1952, when the sea-floor off Cape Campbell was covered with dead *Pyrosoma* at a depth of 100 m. The animals were in an advanced state of decomposition, and were present in quantity in the trawl. Mr. Abernethy informs us that fishermen in this area frequently take dead *Pyrosoma* in this condition at certain times of the year.

The nature of the bottom in the photographs taken is an interesting commentary on conditions apparently suitable for *Pyrosoma*. The bottom is of clean-swept cobbles, completely lacking in the usual fauna found in nearby rocky bottom areas where there is a certain amount of muddy matrix, and indicates a fairly strong current. Measurements of the bottom current were made at Station *C*.122 by Mr. A. E. Gilmour of this Institute, and were found to vary between $\frac{1}{2}$ and $\frac{3}{4}$ knot at 10 in. above the bottom. Surface currents were 1–4 knots, depending on the state of the tidal-cycle. These velocities are representative of average conditions in the relatively constricted passage through Cook Strait. It is reasonable to infer from this that the animals can maintain their position on the bottom despite the current. It may well be that the occurrence demonstrated a positive reaction in *Pyrosoma atlanticum* towards the least rapidly moving water in their immediate vicinity, since the whole water column above them would be moving at a greater rate.

The photographs for this work were taken by Mr. G. R. T. Clacey, of the New Zealand Electricity Department, with an underwater camera, developed in consultation with the New Zealand Oceanographic Institute and the Photographic Section of the Department of Scientific and Industrial Research.

Inhibitory Effect of Colchicine upon the Transplantable Fibroma of the Skin in the Newt *Triturus taeniatus*

Recently, we described a multiple fibroma of the skin in the newt *Triturus taeniatus* which was characterized by an enlargement of the adepidermal reticular network[1-4] and appeared to be transplantable in the same animal[3,4]. The preliminary transplantation experiments were continued to establish the effect of a colchicine treatment. The material for these experiments was obtained by breeding the normal animals of the first litter in which the tumour was observed[3,4]. Fragments of tumour tissue from the surroundings of small tumours, in which an enlargement of the nodular swellings of the adepidermal reticular network could already be expected, were transplanted to a perfectly tumour-free area of the same animal, preferably in the tail base region. In 105 of the 128 cases a distinct tumour developed after about 3 weeks at the location of the transplantation, whereas in the 23 negative cases the transplanted material had been almost completely resorbed. After 3 weeks in 83 of the 105 tumour cases treatment with colchicine was applied, the remaining 22 animals being used as controls. This colchicine treatment consisted in giving once a week an intraperitoneal injection of colchicine–saline solution (0·0017 mgm. colchicine). The method of preparing the solution for injection was as usual[5-7]. The experiment lasted 70 days.

Comparing the area diagrams which were made of the tumours, it was clear that the colchicine had an inhibitory effect on the growth of this fibroma.

The tumours of the colchicine-treated animals as well as of the control animals were examined histologically, and particularly the adepidermal reticular network was studied with the aid of Pap's ammoniacal silver method as modified by Mitchell and Wislocki[8] (counterstain paracarmine) and Bodian silver–proteinate (counterstain orange *G*).

The tumours of the control animals showed the normal development of this fibroma, in which the following stages already described[3,4] were observed: (1) enlargement of the nodular swellings of the adepidermal reticular network; (2) continued enlargement of the nodular swellings and concentration of fibroblasts in their surroundings; (3) formation of new fine fibrils radiating from the enlarged nodular swellings, a densely structured network thus being formed around the concentrated fibroblasts; (4) fusion of the concentrated masses of fibroblasts to larger complexes. The enlarged nodular swellings are probably induction centres which, with the aid of certain chemical substances, cause the local concentrations of the fibroblasts.

In the tumours of the colchicine-treated animals particularly the enlargement of the nodular swellings and the concentration of the fibroblasts appeared to be disturbed. The inhibitory effect of the colchicine is consequently in all probability an inhibition of these processes. The fact that in the colchicine-treated animals these processes, as well as the tumour growth, had come to a stop is an important argument for the assumption that these processes of the adepidermal reticular network play an important part in the development of this skin fibroma.

Effect of Infection with Myxomatosis Virus on the Endoparasites of Rabbits

The widespread and common occurrence of endoparasites in free-living Australian wild rabbits, *Oryctolagus cuniculus* (L.), prompted an investigation into any effect they might have on the severity of infectious myxomatosis in partially resistant animals, or in cases due to attenuated strains of the virus. Although the results so far obtained are based on a small number of rabbits and are insufficient to answer this complicated problem fully, results collected simultaneously on the behaviour of parasites, especially *Graphidium strigosum*, in virus-infected hosts are interesting and worth recording.

Rabbits infected naturally with *Eimeria* spp. (coccidia), *G. strigosum*, and *Trichostrongylus retortaeformis* were caught in the field at the approximate age of six weeks for the purpose of testing for the degree of genetic resistance to myxomatosis. Prior to inoculation with *K.M.* 13 attenuated strain of virus[1] at about five months, they were kept in the laboratory under conditions which excluded the possibility fo re-infection. For one week before inoculation, and then throughout the course of the disease, fæcal counts of oocysts and nematode eggs were carried out at 2-day intervals in 12 rabbits.

Statistical analysis of the results showed that after generalization of the virus in the host, seven days after inoculation, a significant ($P < 0{\cdot}05$) reduction in the numbers of oocysts and ova occurred, which lasted for approximately 2 weeks—a period coinciding with the acute stage of the disease. The reason for this was not studied specifically, and it is only suggested that the changing metabolism in the host or its increasing body temperature may have induced conditions unsuitable for the development of the parasites. Similarly, Reid *et al.*[2], studying the effects of *Ascaridia galli* on chicks with infectious bronchitis, recently reported a highly significant reduction of worms due to the virus infection; and common observation suggests that the burden of worms decreases markedly in dogs affected by distemper (Soulsby, E. J. L., personal communication).

After the reduction induced by the virus infection a significant ($P < 0{\cdot}05$) increase was recorded generally in numbers of ova but not of coccidia. In only a few animals were counts unchanged—these survived, whereas all those showing an increase died, some when complete recovery from myxomatosis had been expected. Post-mortem examination revealed that the level of infestation with *G. strigosum* was very high in some animals; more than 5,000 worms per rabbit were counted in some cases—a degree of infestation not previously recorded in large samples of normal rabbits caught in the field[3]. These worm populations consisted of newly hatched adults and fourth-stage larvæ, in spite of the fact that all rabbits had been protected from re-infestation with endoparasites.

Michel[4], while studying the problem of the resistance of rabbits to infestation with *T. retortaeformis*, found that in hosts already infested the development of superimposed larvæ is inhibited, and they remain dormant in the intestinal mucosa until conditions become more favourable. It seems that a similar mechanism operates in infestation with *G. strigosum*. The expulsion of adult worms during the early stages of infection with the virus, and the lowered resistance of the host due to the prolonged disease, probably create conditions under which dormant larvæ may resume development and so aggravate the severity of myxomatosis.

I reported earlier another form of interference between endoparasites and virus, which was manifested by inhibition of myxomatosis symptoms and premature death in heavily parasitized animals[5].

Long-term Survival of Irradiated Mice treated with Homologous Tissue Suspensions

Recently, Barnes *et al.*[1] reported the survival for 150 days of *CBA* mice subjected to a dose of 950 r. X-radiation and treated with spleen or liver suspensions from new-born or unborn *C57BL* mice. In an attempt to clarify the secondary phase of the irradiation death syndrome, Uphoff[2] observed the 90-day survival of $(C57BL \times DBA/2)F_1$ hybrids subjected to 800 r. X-radiation following injections of suspensions made from *C57BL* or *DBA*/2 tissues. She reported that the use of fœtal hæmatopoietic tissues precluded the secondary phase of the irradiation syndrome for 90 days after irradiation, whereas injection of bone marrow suspensions did not.

Table 1. Effect of *CF* No. 1, *C57BL*/6, or LAF_1 Tissue Suspensions on Survival of 10- to 12-week-old *CF* No. 1 Female Mice exposed to 750 r. Total-body X-radiation.
Controls consisted of 10 untreated *CF* No. 1 mice, all of which survived 270 days; 9 survived 400 days and 7 survived 500 days; 2 were still alive at 910 days

Donor tissue	No. of mice treated	No. surviving at intervals shown (days) 28	150	270	400	500	Day of last death
CF No. 1 bone marrow (7- to 8-week mice)	36	23	20	17	8	2	515
C57BL/6 bone marrow (7- to 8-week mice)	36	3	0	0	0	0	121
CF No. 1 baby spleen	44	24	16	9	4	1	525
C57BL/6 baby spleen	50	30	9	5	1	0	406
LAF_1 baby spleen	34	18	11	6	2	0	483
CF No. 1 embryo liver	45	34	31	24	16	1	546
C57BL/6 embryo liver	69	27	18	11	2	1	497
Locke's solution	75	5	3	1	0	0	365

In 1956 [3] we observed that no secondary deaths occurred when lethally irradiated rabbits were injected with embryonic or new-born mouse tissues, and that rabbits so treated were alive after 150 days. Many of these rabbits are, in fact, still alive after three and a half years. We had previously reported in 1954 [4] that suspensions made from fœtal *CF* No. 1 mouse liver, or spleen and liver from new-born mice, were more effective, on the basis of cell counts, than suspensions of mature tissue in enhancing the 30-day survival of irradiated (900 r.) mice of the same strain. *CF* No. 1 mice which were treated with hæmatopoietic tissues from young or unborn *CF* No. 1, *C57BL*/6, or LAF_1 mice following 750 r. total-body X-irradiation have now lived out their life-span, and the long-term survival results are shown in Table 1. Irradiated *CF* No. 1 mice survived longer when injected with fœtal liver or spleen suspensions from new-born mice than when treated with an equal number of *C57BL*/6 or *CF* No. 1 bone marrow cells.

Although the *CF* No. 1 strain is no longer maintained by strict inbreeding, post-irradiation treatment with *CF* No. 1 fœtal or new-born tissues resulted in longer survival than did similar treatment with *C57BL*/6 or LAF_1 tissues.

Red Muscle as a Possible Character for the Identification of Sharks

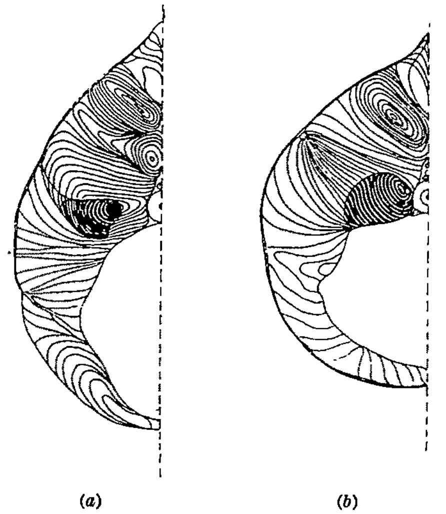
In a previous communication, the relative distribution of vitamins between the red muscle and the ordinary muscle in fish was reported[1]. The relation between the proportion of red muscle present and the activity of different species was pointed out, and the possible function of the red muscle as an organ proposed.

Since then studies have been in progress, including recording the extent of the red muscle in the different species investigated. By chance these studies have led to an interesting observation in the two closely related pelagic sharks of the family Isuridae or mackerel sharks.

The main studies were carried out with the porbeagle (*Lamna nasus*[2], syn. *Lamna cornubica*[3] or *Isurus nasus*[4,5]), the mackerel shark caught off the coast of Norway. Although this species is caught also in the warmer parts of the Atlantic and in the Mediterranean, it seems present mainly in the northern part of the Atlantic. The very closely related sharp-nosed mackerel shark or mako (*Isurus oxyrinchus*) lives mainly in the warmer parts of the Atlantic and is very rarely caught off the coast of Norway or in the north.

The two species are very alike, but certain distinctive characters, such as the teeth and the position of the dorsal and ventral fins, can be used for their identification. The porbeagle also has a stouter trunk than the mako. They are both very active and strong-swimming species which prey mainly upon shoals of scombroids, clupeids and other small fishes.

By chance a 'trunk' of a mackerel shark caught off the coast of Morocco was brought to this Institute for comparison with regard to palatability and quality with the porbeagle caught off the coast of Norway. During routine sampling and recording of the red muscles of these sharks, a very typical difference in the location of the red muscle in the two species was observed. While the red muscles in the porbeagle only extended partly along the trunk and were mainly situated close to the vertebra and the body-cavity, the red muscles in the mako extended all along the trunk and did not lie directly up against the vertebra. Fig. 1 shows transverse sections of the two species at the thickest part of the red muscles. Both fishes had a gutted weight of 13 kgm. Differences caused by stages in development thus could be discounted. Both species are very alike, and it is actually very difficult to identify them as delivered at the fish market, although the transition from stone-grey colour on the dorsal to white on the ventral side changes abruptly on the porbeagle and gradually on the mako. The present observation shows that the position of the red muscle in this case gives a good character for the distinction between closely related species. To my knowledge, this character has never been proposed or used for identification purposes in fishery research. It is apparently specially useful for pelagic species with distinct red muscles. The usefulness of the proposed character will have to be established by further investigations by marine biologists working in this field.



(*a*) (*b*)

Origin of Indirect Flight Muscles in Primitive Flies

It is generally supposed that among endopterygote insects the flight muscles of the adult first arise in the pupal stage. For example, in the higher Diptera (*Drosophila*[1,2], *Calliphora*[3]) the development of the indirect flight muscles is said to begin at pupation when free myoblasts adhere to or penetrate certain larval muscle fibres. In the early pharate[4] pupa of the Neuroptera[5] and Coleoptera[6,7], larval muscle is directly transformed into adult muscle: in certain larval muscles some nuclei degenerate and others undergo mitosis and persist as the nuclei of the adult flight muscle. In some Hymenoptera (*Mormonella*[8]) the adult muscles arise from free myoblasts as in the higher Diptera, whereas in others, such as the honey-bee[9], the imaginal myoblasts are contained in the larval muscle, as in the Neuroptera and Coleoptera.

In the Simuliidae, however, the indirect flight muscles and the tergal depressor of the trochanter develop quite independently of the larval muscles in all post-embryonic stages. So far as may be judged from the account given by Hulst[10], the indirect flight muscles of *Culex* also develop independently of the larval muscles. In the mesothorax of the Simuliidae there are six groups of indirect flight muscles. These consist on each side of 6 dorso-longitudinal, 2 oblique dorsal, 2 tergo-meral, 2 tergo-sternal, 3 outer tergo-pleural, and 2 inner tergo-pleural. In *Simulium ornatum* Meig., in which there are six larval instars, the imaginal disks of the indirect flight muscles and that of the tergal depressor of the trochanter are present in the second instar larva 1·3 mm. long. In the first instar larva the disks of the dorso-longitudinal muscles are present but those of the dorso-ventral muscles have not yet been identified with certainty.

In the young larva the disks of the indirect flight muscles consist of slender strands attached at either end to the epidermis but not to the cuticle (Fig. 1). Each of these strands is a sleeve of sarcolemma enclosing a syncytium with a few nuclei. The strands grow in length and thickness as the larva grows so that their size relative to that of the mesothorax is maintained. The nuclei are similar in size in all

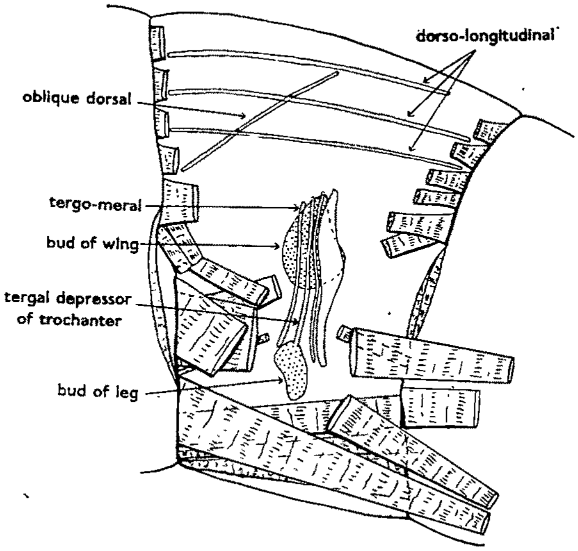

Fig. 1. Mesothorax of penultimate larval instar of *Simulium ornatum* Meig. Larval muscles shaded, disks of imaginal muscles unshaded

larval stages : 4–6μ. In very young larvæ the strands are often thinner than the nuclei so that they bulge where nuclei are present. As the larva grows the number of nuclei increases by mitosis. The mitotic divisions appear indistinguishable from those of the epidermis.

After the larval–pupal moult but before the larval–pupal ecdysis, that is, in the pharate[4] pupal stage, there is a rapid increase in the size of the imaginal strands, and mitotic figures are numerous both during the day and the night. Before the larval cuticle is shed, mitosis appears to have come to an end, and the nuclei have become arranged in longitudinal rows. Also before the larval–pupal ecdysis the imaginal strands have become divided so that there are now clearly 17 on each side plus the tergal depressor of the trochanter. It is during the pharate pupal period that differences between the organization of the fibrillar tergal depressor of the trochanter and the indirect flight muscles are first discerned. The indirect flight muscles and the tergal depressor of the trochanter continue to grow in size after the larval cuticle is shed and after the pupal–adult moult. At this time growth in volume is accompanied by a degeneration of the nuclei.

In the young pharate pupa the shape of the thorax and the relative proportions of its three segments are as in the last larval instar. The great increase in the extent of the mesothorax and the great reduction in the extent of the pro- and meta-thorax occur during the pharate pupal period, especially near the end of this period. The epidermis of the thorax assumes its final 'humped' shape at the moment that the larval cuticle is being shed, and it is this change in shape that effects the first split in the larval cuticle. The change in shape is brought about by an increase in turgor pressure due to the contractions of the muscles carried over directly from the larval stage, but it is made possible by the enormous increase in area of the mesothoracic epidermis that occurs after the larval–pupal moult but before the larval cuticle is shed. After the larval–pupal ecdysis, the shape of the thorax is essentially that of the adult, although in some other Nematocera, such as the Thaumaleidae[11], the metathorax is reduced in the pharate pupal period and the prothorax in the pharate adult period.

The indirect flight muscles and the tergal depressor of the trochanter do not become contractile, cross striated, or birefringent until some hours after the first layers of the adult cuticle have been secreted. It therefore follows that they can play no direct part in the change of shape that occurs when the pupa sheds the larval cuticle, as they have been said to do in *Drosophila*[12]. During growth the muscles do not shift their attachments to the epidermis, but the epidermis of different parts of the mesothorax grows at different rates. It is this differential growth of the epidermis that directly determines changes in the position and orientation of the indirect flight muscles, changes that are particularly evident as the newly enlarged epidermis of the mesothorax is stretched during the shedding of the larval cuticle. So far as the mesothorax is concerned, all larval muscles except one are carried over without evident modification into the pupal stage, and no new muscles that function in the pupal stage are developed in that stage. Histolysis of the larval muscles becomes evident only in the pharate adult stage, and their destruction is not completed until about 30 hr. (at 8° C.) after the pupal–adult moult.

In some other Diptera–Nematocera the indirect flight muscles would appear to develop in a similar way. The imaginal disks of the dorsal longitudinal or both dorsal longitudinal and dorso-ventral muscles have been identified in the last larval instar of the Tipulidae (*Taphrophila*, *Geranomyia*), Dixidae, Culicidae (*Aedes aegypti* L.), Chironomidae (*Chironomus*), and Thaumaleidae.

Goniotrichum elegans: a Marine Red Alga requiring Vitamin B_{12}

THE cultivation of multicellular marine algae under laboratory conditions has always proved to be a matter of difficulty. Most species die after a few months even if cultivated in seawater or enriched seawater. Henkel[1] succeeded in cultivating *Bangia pumila* through several generations in an artificial medium, but she did not work with pure cultures. Koch[2] produced an axenical culture of *Porphyridium cruentum*. His medium was not, however, chemically defined since it contained natural water.

I have tried to cultivate several marine algae in completely defined nutrient medium. To that purpose medium *ASP* 6 was used[3], but without copper and cobalt, and with potassium-glycerophosphate replaced by 10 mgm. dipotassium hydrogen phosphate per litre. *Goniotrichum elegans* (Chauv.), a small epiphytic member of the Bangioideae with a

Table 1. GROWTH OF *Goniotrichum elegans* WITH COBALT OR VITAMIN B_{12}

The figures represent the total dry weight produced in all six flasks of each series. Incubation time, 4 weeks

No addition	Dry weight of alga (mgm.)	
	Cobalt (10 μgm./l.)	B_{12} (1 μgm./l.)
0·9	0·7	6·9

dichotomously ramified monosiphonous thallus, was among the species treated. It produced good growth in *ASP* 6, and since May 1957 it has been cultivated through repeated re-inoculations in 100-ml. 'Pyrex' flasks with 25 ml. nutrient solution per flask, in fluorescent light (900 lux) at 20° C. Diatoms and other small algae were removed by washing and careful manipulations. By treating small samples of the alga with phenoxymethylpenicillin (1,000 units per ml.) combined with streptomycin sulphate (Glaxo, 500 units per ml.)[4] of contaminating bacteria were killed and a completely axenical culture was obtained. The treatment had to proceed for 12–14 days to give a satisfactory result. The purity has repeatedly been controlled according to the test described by Pringsheim[5]. When it was used in the following experiments the strain had remained axenical for 3½ months.

The requirement of growth substances was studied. The medium *ASP* 6 contains all available vitamins. In the first experiment the exclusion of the vitamins did not seem to slow down growth. The experiment was repeated, however, and as inocula the algae from the vitamin-free series of the former experiment were used. The following series were inoculated: (*a*) without vitamins; (*b*) with B_2, B_{12}, pyridoxamine and folic acid, run through sterile glass filter and added aseptically; (*c*) with the remaining 11 vitamins, sterilized together with the nutrient solution. Visible growth appeared only in series *b*.

Several marine algae and bacteria have turned out to be dependent[6] on an exogenous source of vitamin B_{12}. This vitamin was therefore suspected to be the active member of the vitamin mixture. Since in all experiments hitherto no cobalt had been added to the nutrient solution, there was a possibility that B_{12} acted only as a cobalt source[7]. In a following experiment cobalt (10 μgm. per litre) and B_{12} (1 μgm. per litre) were added to two different series (Table 1). As inocula, pieces of *Goniotrichum* from the vitamin-free series of the preceding experiment were used, which had been cultivated for 50 days, and during this time transferred three times into new cobalt- and vitamin-free nutrient solution. The inocula were pale and partly dead.

As Table 1 shows, good growth appeared only in the B_{12} series, while the addition of cobalt had no effect. Ericson and Lewis[8], who worked with labelled cobalt and B_{12}, found that some red algae could transfer cyanocobalamin into other B_{12} factors, though additions of B_{12} gave no stimulation. They assumed that B_{12} was produced by bacteria and then accumulated by the algae, but they had no proof of the vitamin being necessary for the algae as they did not work with pure cultures. The experiments with *Goniotrichum elegans* thus add a member of the Rhodophyta to the list of vitamin B_{12} heterotrophic algae. Pintner and Provasoli[9] have shown that a marine red pigmented blue-green alga, *Phormidium persicinum*, also needs exogenous vitamin B_{12}. This similarity of vitamin requirement may perhaps support the theory of a relationship between blue-green algae and red algae.

Effect of Boron on the Rooting of Clematis Cuttings

BORON has been observed to stimulate the rooting of large-flowered hybrid clematis cuttings. In two studies recently carried out, increased percentages of cuttings rooted and the rooting process was accelerated by boron when it was used in combination with the root-initiating hormone, indole butyric acid.

Previously, stimulation by boron of the rooting of *Phaseolus vulgaris* L. cuttings was noted by Hemberg[1] and verified by Gorter[2]. Although relatively little is known about the nature of this stimulative action, Hemberg[1] and Rehm[3] have stated that root growth, and not root initiation, is favoured by this element.

In the first study, 180 two-node cuttings were taken on June 14, 1958, from new growth of clematis selection 234, a seedling of Crimson Star. Cuttings were divided into four lots of 45 each and the bases of the cuttings in each of these lots were soaked for 12 hr. in one of the following aqueous solutions: 50 p.p.m. indole butyric acid; 50 p.p.m. boron, supplied as boric acid; 50 p.p.m. indole butyric acid plus 50 p.p.m. boron; and water. Following these treatments the cuttings were placed in washed sand on the propagating bench under an intermittent mist system which came on for 15 sec. out of every 3 min. during the daylight hours. The temperature of the sand was maintained at approximately 75° F. by heating cables. Air temperature was 65° F. at night and usually higher during the day, occasionally reaching a maximum of 85° F.

The percentage of cuttings rooted in each treatment after 32 days and after 54 days is recorded in Table 1.

Table 1. RESPONSE OF CLEMATIS SELECTION 234 TO THE ROOTING TREATMENTS

Treatment	Rooting	
	After 32 days (per cent)	After 54 days (per cent)
Water	6·7	33·3
Indole butyric acid	24·4	55·6
Boron	17·8	62·2
Indole butyric acid + boron	66·7	86·7

It is evident from these figures that boron stimulated the rooting of cuttings when it was used in combination with indole butyric acid, and to a lesser extent when it was used alone. A comparison of the rooting percentages at the two observation dates indicates indole butyric acid plus boron accelerated rooting in addition to increasing the percentage of cuttings which rooted.

Table 2. RESPONSE OF NINE CLEMATIS SELECTIONS TO THE ROOTING TREATMENTS

Selection No.	Rooting after 36 days			
	Water (per cent)	Indole butyric acid (per cent)	Boron (per cent)	Indole butyric acid + boron (per cent)
181	100	60	80	90
51	60	80	20	90
217	0	50	20	100
169	20	40	40	50
31	80	90	100	90
32	80	90	60	80
94	0	70	0	100
54	40	60	40	70
159	40	80	40	90
Treatment average after 36 days	46·7	68·9	44·4	84·4
Treatment average after 56 days	53·3	74·4	53·3	85·6

In the second study 30 two-node cuttings were taken on July 24, 1958, from each of 9 numbered clematis selections of diverse parentage and were given the four treatments described in the first study. Cuttings were divided into lots of unequal size so that 10 cuttings of each selection received the indole butyric acid and indole butyric acid plus boron treatments while 5 cuttings of each selection received the boron and the water treatments. The rooting conditions on the cutting bench were the same as those described in the first study. Table 2 shows the treatment averages after 36 days and 56 days and the percentage rooting of each selection after 36 days.

Selections varied considerably in response to the treatments, but the treatment averages in general substantiated the results obtained in the first study. In particular, the high rooting percentage of the indole butyric acid plus boron treatment and the acceleration of the rooting process by the boron in that treatment agreed with the results of the former study. A notable exception is the lack of increased rooting in the boron treatment as compared with the water check. This lack of increased rooting seems to support the views of Rehm[3] and Hemberg[1] that boron promotes root growth and not root initiation. If applied to the indole butyric acid and indole butyric acid plus boron treatments, this concept implies that cuttings in both treatments may have formed the same number of root initials as a result of the initiation stimulus of indole butyric acid, but that more roots grew in the treatment with indole butyric acid plus boron due to the growth stimulus of boron. Nevertheless, other possible explanations of this boron stimulation, such as a boron enhancement of the effectiveness of indole butyric acid in stimulating root initiation, seem equally plausible in these studies. Further investigation is necessary to elucidate the role or roles of boron in rooting cuttings.

Results of studies which indicate that boron also enhances the rooting of cuttings of certain varieties of rhododendrons and English holly (*Ilex aquifolium* L.) will be published elsewhere.

I am indebted to Dr. L. T. Blaney for his helpful suggestions.

Crowned Cranes in Cambridgeshire

FOUR crowned cranes (*Balearica pavonina*) recently appeared in an area of arable and marshy country in Cambridgeshire. This species, so far as we know, has not previously been described as occurring at large in Britain, although one specimen was shot in Ayrshire in 1871, and had "doubtless escaped from captivity"[1].

The birds appeared in their present haunts in August 1958, or possibly earlier. They were last seen on January 24. Two were adult; the other two, from their more buff-coloured plumage, appeared to be immature.

All exhibited the straw-coloured crown characteristic of the species and the elongated secondaries typical of cranes. The white facial patch behind the eye was very conspicuous; the red area behind it was clearly seen but more difficult to define. The neck appeared dark grey or black according to the lighting.

In flight the neck and legs were extended, and with the back, formed a dorsal convex curve. The crown was laid close to the neck. The large white wing was edged at the tip and along its hind margin with black primaries and secondaries. It presented a digitated appearance at its extremity. A gap in the secondaries could be seen when the wing was viewed from below. The birds' flight was powerful and at times swift, direct and purposeful when compared with that of the heron. Landing was preceded by a glide, and lowering the legs produced a braking effect by opposing the under surface of the wings to the direction of flight. The birds were usually seen flying in line ahead, and any tendency for the group to become split up was checked by a repeated honking call from the leader.

Owing to the wet summer in 1958, several fields of barley in the locality now frequented by these cranes were left unharvested. They have been commonly observed feeding on the uncut barley and gleaning among the stubble.

They were alert and very shy, and careful stalking has been required to approach within fifty yards. On taking wing they travelled 400–1,000 yards and then once more alighted to continue feeding. Once the larger of the two adults was seen to perch on a tree, where it acted as sentinel. The remaining three partially concealed behind a broken hedge could be seen with necks craned in a characteristic posture.

From their extreme wariness we do not believe that these birds have escaped from captivity; but this cannot be ruled out without a complete record of recent escapes of this species. We have now had them under observation for more than two months and attempts to photograph them, with or without 'hides', have met with little success. We should add that since January 10 only three cranes have been seen; the fate of the fourth, an immature bird, is unknown.

We are indebted to Prof. R. A. McCance for valuable help and advice.

University of London Institute of Education (in the Assembly Hall, Malet Street, London, W.C.1), at 5.30 p.m.—Dr. R. S. Peters: "Education and Explanation—an Examination of Ways in which Theories of Learning are Relevant".*

University of London (at King's College, Strand, London, W.C.2), at 5.30 p.m.—Prof. E. W. Montroll (University of Maryland): "Theory of Vibration of Crystal Lattices".* (First of three lectures on "Statistical Mechanics". Further lectures on February 24 and 25.)

Institut Francais du Royaume-Uni (at Queensberry Place, South Kensington, London, S.W.7), at 8.30 p.m.—Programme of French Scientific Films. (By invitation obtainable from the Scientific Office, French Embassy, 22 Wilton Crescent, S.W.1).

Tuesday, February 24

University College (in the Anatomy Theatre, Gower Street, London, W.C.1), at 1.15 p.m.—Prof. W. B. Emery: "Excavations at Buhen, Sudan".*

University College (in the Anatomy Theatre, Gower Street London, W.C.1), at 5.30 p.m.—Prof. G. C. Drew: "Aspects of the Investigation of Skilled Performance".*

Society of Instrument Technology, Control Section (at Manson House, Portland Place, London, W.1), at 6 p.m.—Symposium on "Automatic Weight Control in Industry".

Society for Analytical Chemistry, Physical Methods Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Meeting on "The Analysis of Intact Samples".

Royal Aeronautical Society (at 4 Hamilton Place, London, W.1), at 7 p.m.—Dr. A. E. Russell, Mr. C. Abell and Dr. E. Warlow-Davies: "The Flight Development of an Aircraft Before and During its Operation".

Wednesday, February 25

Geological Society of London (at Burlington House, Piccadilly, London, W.1.), at 5 p.m.—Dr. J. L. Knill: "The Tectonic Pattern in the Dalradian of the Craignish–Kilmelfort District, Argyllshire"; Dr. P. Clifford: "The Geological Structure of the Loch Luichart Area, Ross-shire" (to be read by Prof. J. Sutton).

Royal Society of Medicine, Endocrinology Section (at 1 Wimpole Street, London, W.1), at 5 p.m.—Discussion on "The Chemical, Pharmacological and Clinical Aspects of the 19-nor-steroids". Opening Speakers: Dr. W. Klyne, Dr. J. C. Eaton, Dr. T. M. Chalmers, Dr. G. I. M. Swyer, Dr. Margaret C. N. Jackson and Mr. J. A. Chalmers.

Institute of Fuel (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 5.30 p.m.—Dr.-Ing. H. Lent: "Investigations in Germany concerning Atmospheric Pollution".*

Institution of Mechanical Engineers, Applied Mechanics Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "The Significance of Thermal Stresses in Design".

Society of Chemical Industry (joint meeting of the Food Group and the Microbiology Group, at 14 Belgrave Square, London, S.W.1), at 6.15 p.m.—Meeting on "Cheese Manufacture and Microbiology". Dr. K. Mabbit: "Microbiological Aspects"; Miss V. Cheke: "Technological Aspects".

British Institution of Radio Engineers (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6.30 p.m.—Mr. E. D. Swann: "Patents and the Radio Engineer".

Oil and Colour Chemists' Association (at Manson House, 26 Portland Place, London, W.1), at 7 p.m.—Mr. D. M. James: "The Moisture Resistance of Cold-Cured Epoxide Resin Paints".

British Psychological Society, Social Psychology Section (at Birkbeck College, Malet Street, London, W.C.1), at 8 p.m.—Annual Meeting. Paper by Prof. Angus Campbell.

Thursday, February 26

University College (in the Anatomy Theatre, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. K. A. Sinnhuber: "Alexander von Humboldt (d. 1859), Traveller, Geographer, Philosopher".*

Institution of Industrial Safety Officers (at the Royal Society of Arts, John Adam Street, London, W.C.2), at 2.30 p.m.—Mr. R. E. Tugman, M.B.E.: "The Responsibility of Management for the Prevention of Industrial Accidents" (First Alexander Redgrave Memorial Lecture).

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Miss Ann B. Glossop and Mr. D. W. Pashley: "The Direct Observation of Anti-phase Domain Boundaries in the Ordered Copper-Gold (Cu-Au) Alloy"; Mr. J. Grindlay and Mr. D. ter Haar: "On the Ferro-electric Behaviour of Potassium Dihydrogen Phosphate".

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. Peter David: "Exclusive Distribution of Certain Species of Chaetognaths"; Dr. M. H. Williamson: "Effects of Inter-Specific Competition".

Physical Society, Acoustics Group (at the Royal Academy of Music, Marylebone Road, London, N.W.1), at 5.30 p.m.—Discussion on "Of What Use is Acoustics to the Musician?"

Chemical Society (in the Lecture Theatre, The Royal Institution, Albemarle Street, London, W.1), at 7.30 p.m.—Prof. F. Hoyle, F.R.S.: "The Origin of the Elements".

Friday, February 27

Institute of Rural Life at Home and Overseas (at Friends International Centre, 32 Tavistock Square, London, W.C.1), at 1.15 p.m.—Mr. C. W. A. Garland: "Higher Education in British Africa".*

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.15 p.m.—Geophysical Discussion on "Characteristics of the Antarctic Ice Sheet". Chairman: Dr. J. F. Nye. Speakers: Monsieur B. Imbert, Dr. H. Lister and Mr. J. G. D. Pratt.*

Institution of Mechanical Engineers (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Informal Discussion on "Choice of Gas Temperature and Steam and Pressure Conditions in Nuclear Power Stations".

Malacological Society of London (at the Linnean Society, Burlington House, Piccadilly, London, W.1), at 6 p.m.—Discussion on "The Status of the Protobranchia within the Bivalve Mollusca".

Manchester Statistical Society, Industrial Group (in the Portico Library, 57 Mosley Street, Manchester), at 6 p.m.—Dr. A. Baines: "Applications of Linear Programming Techniques to Problems of Production and Distribution".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. C. H. Waddington, F.R.S.: "Evolutionary Systems—Animal and Human".

Saturday, February 28

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Dr. Guy Atkins: "African Sculpture and Western Art".*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Lecturer in Microbiology—The Secretary, The Queen's University, Belfast (February 28).

Research Fellow in the Department of Pharmacology—The Secretary, Royal Free Hospital School of Medicine (University of London), 8 Hunter Street, London, W.C.1 (February 28).

Assistant (with an honours degree in physiology or an allied subject and preferably a medical degree) in the Department of Physiology—The Secretary, The University, Edinburgh (March 1).

Assistant Lecturer, Grade B (with qualifications in numerical analysis) in the Department of Mathematics—The Clerk to the Governors, Chelsea College of Science and Technology, Manresa Road, London, S.W.3 (March 2).

Scientist (with at least a second-class honours degree or equivalent) at the Research and Development Laboratories, Capenhurst, Chester, to work on the development of infra-red absorptiometers and on allied infra-red and optical instrumentation problems, involving the design and use of optical and infra-red systems, techniques of absorption spectroscopy and application of modern electronic methods—The Recruitment Officer, U.K.A.E.A., I.G.H.Q., Risley, Warrington, Lancashire, quoting Ref. 2938/114 (March 2).

Lecturer or Senior Lecturer in Mathematics at the University of New England, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, March 6).

Assistant Lecturer (with a good honours degree in agricultural chemistry, chemistry or physics, and preferably an interest in soil physics) in Agricultural Chemistry—The Registrar, The University, Leeds 2 (March 11).

Lecturer or Assistant Professor (with a Ph.D. degree in mathematics or in applied mathematics)—The Chairman, Mathematics Department, McMaster University, Hamilton, Ontario, Canada (March 15).

Reader in Bacteriology at St. George's Hospital Medical School—The Academic Registrar, University of London, Senate House, London, W.C.1 (March 16).

Reader in Morbid Anatomy at St. George's Hospital Medical School—The Academic Registrar, University of London, Senate House, London, W.C.1 (March 16).

Assistant Lecturer (with special qualifications in micropalæontology) in the Department of Geology—The Registrar, University College of Wales, Aberystwyth (March 21).

Lecturers or Assistant Lecturers in the Department of Physics—The Registrar, The University, Leeds 2 (March 21).

Mullard Research Fellow (preferably with a Ph.D. degree or equivalent research experience) in Physics—The Registrar, University College of North Staffordshire, Keele, Staffs (March 30).

Chair of Bacteriology in the University of Malaya—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (March 31).

Chair of Engineering; Chair of Chemistry; Chair of Biology; Vice-Chancellor; and Librarian at Monash University, Melbourne, Victoria, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (March 31).

Lecturer (preferably with experience in semiconductor applications or electronic computers) in Light Electrical Engineering—The Secretary, The Queen's University, Belfast (March 31).

Principal (with high academic qualifications and appropriate educational and administrative experience)—Clerk to the Governing Body, Northern Polytechnic, Holloway, London, N.7 (March 31).

University Demonstrator (with an honours degree in zoology) in Zoology—The Secretary of the Appointments Committee of the Faculty of Biology "A", Botany School, The University, Downing Street, Cambridge (March 31).

Assistant Lecturer (with appropriate qualifications, specializing in either pure or applied mathematics) in Mathematics at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Hong Kong, April 3).

Imperial Chemical Industries Research Fellows in Biochemistry, Chemistry, Chemotherapy, Engineering, Metallurgy, Pharmacology or Physics—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 30).

Turner and Newall Research Fellows in Engineering, Inorganic Chemistry or Physics—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 30).

Assistant Lecturer in Mathematics—The Secretary, Royal College of Science and Technology, Glasgow.

Associate Professor of Pharmacology—The Dean of Medicine, University of Alberta, Edmonton, Alberta, Canada.

Head (man or woman) of the Department of Chemistry—The Headmaster, Weymouth Grammar School, Weymouth, Dorset.

Junior or Student Technician (preferably with experience in histological work and/or microphotography) in the Anatomy Department—The Secretary, St. Mary's Hospital Medical School, Paddington, London, W.2.

Lecturer in Telecommunications, to teach up to the full Technological Certificate of the City and Guilds of London Institute and the Grad.Brit.I.R.E.—The Clerk to the Governors, Northern Polytechnic, Holloway, London, N.7.

Lecturer or Senior Lecturer in Chemistry; and a Principal Lecturer in Education—The Warden, University of London, Goldsmith's College, New Cross, London, S.E.14.

Research Assistant (male or female) in Biochemistry, for work in the Research Laboratory—The Medical Superintendent, Western General Hospital, Crewe Road, Edinburgh 4.

Senior Lecturer (qualified to direct research and to teach to Honours Degree or Diploma in Technology levels, and preferably industrial experience in a responsible position) in Textile Physics—The Registrar, Institute of Technology, Bradford 7.

Senior Lecturer (with good academic qualifications, and experience in automatic control, preferably involving pneumatic or hydraulic systems) in Mechanical Engineering—The Registrar, Loughborough College of Technology, Loughborough, quoting Ref. 1/G.

Senior Technician or Chief Technician (preferably with experience in biochemistry), to work at Sheffield Royal Hospital—The Bursar, Department of Medicine, The University, Sheffield 10.

Teaching Assistants (qualified Ph.D. candidates)—Prof. H. B. Collier, Department of Biochemistry, University of Alberta, Edmonton, Alberta, Canada.

HIGH RESOLUTION WITH NEW INFRARED GRATING COMPONENT

The new SP.130 Grating Accessory for the Unicam Infrared Spectrometer employs two diffraction gratings of the Merton replica type, ruled at 1,500 and 3,000 lines/inch respectively for the ranges 650—2,150 cm^{-1} and 2,150—3,650 cm^{-1}. Selection of the appropriate grating (or reversion to single prism monochromator) is by simple push-button control. Added to the rocksalt prism of the basic instrument, the accessory makes available a prism/grating double monochromator with exceptional resolving power and low stray light characteristics. These features combine with the outstanding photometric accuracy of the SP.100 spectrometer to provide an instrument well suited to the increasingly important field of intensity measurements at high resolution.

The Grating Accessory can be supplied as a component part of the Spectrometer or can be fitted by Unicam engineers to instruments already in service.

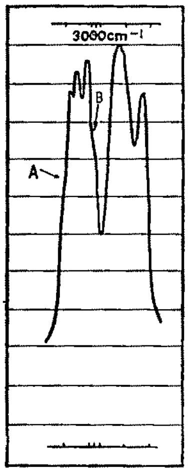

Fig. 1

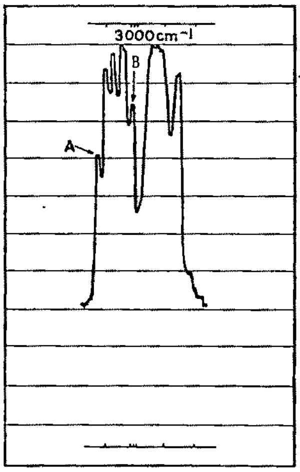

Fig. 2

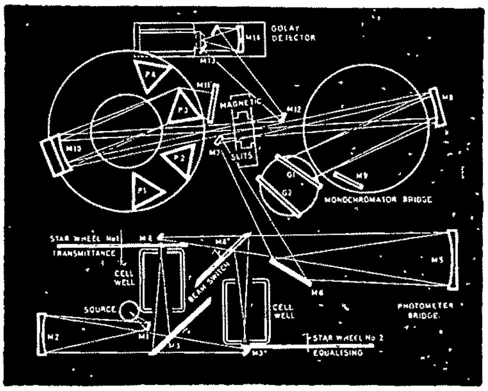

Schematic optical layout of prism/grating double monochromator

The two polystyrene spectra shown were run under exactly similar instrument conditions, fig. 1 on the standard spectrometer with rocksalt prism, fig. 2 on an instrument fitted with prism/grating double monochromator. The improvement in resolution is clearly shown by a comparison of the points marked A & B which appear as inflections in fig. 1 and are resolved as secondary peaks when the grating is used.

The SP.130 accessory further increases the range and power of the SP.100 Spectrometer and helps to provide all the facilities required for the most advanced infrared techniques.

Œstrous Cycle, Gestation Period and Parturition in the Marsupial *Trichosurus vulpecula*.—Dr. A. G. Lyne, Phyllis E. Pilton and G. B. Sharman 622

A Relationship between some Bacteria, Protozoa and Diet in Early Weaned Calves.—J. Margaret Eadie, Dr. P. N. Hobson and S. O. Mann . 624

A Photographic Method for recording Activity and Behaviour in a Group of Small Animals.—Dr. D. K. Edwards 625

Photochemical Reduction of Blue Tetrazolium by Isolated Chloroplasts.—John J. Taylor and Prof. Meyer Chessin 626

Physiological Races of *Phytophthora infestans* Mont. (de Bary) in Northern Ireland.—K. G. Proudfoot 626

Feulgen Reaction in the Fucales.—Dr. M. Naylor 627

Leaf-Enations in *Dahlia variabilis* Desf. induced by Tomato Spotted Wilt Virus.—A. A. Brunt 627

PATHOLOGY

Effect of Neutral Red on Plaque Formation by Fowl Plague Virus.—Dr. A. P. Waterson . 628

Local Inhibition by Lactation of chemically induced Breast Tumours in Mice of the *IF* Strain.—June Marchant 629

Increase of Viral Hæmagglutinability of Red Cells of the Mouse after Treatment with Formalin.—B. Fauconnier and D. Barua 629

DIFCO microbiological reagents and media

Bacto-Dehydrated Media for Microbiological Assay of
VITAMINS and AMINO ACIDS

These *media* contain all the necessary nutriments for the growth of specified test organisms for the microbiological assay of vitamins and amino acids except for the component under assay. These basal media require only the addition of specified increasing amounts of the vitamin or amino acid being assayed to obtain a growth response which may be measured by acidimetric or turbidimetric methods for the construction of standard curves. The vitamin or amino acid content of the material under assay is determined by adding appropriate concentrations of the test substance to the basal medium and comparing the growth response obtained with that of the standard.

BACTO-RIBOFLAVIN ASSAY MEDIUM
BACTO-NIACIN ASSAY MEDIUM
BACTO-THIAMIN ASSAY MEDIUM
BACTO-PANTOTHENATE ASSAY MEDIUM
BACTO-B_{12} ASSAY MEDIUM USP
BACTO-CS VITAMIN B_{12} AGAR
BACTO-FOLIC ACID ASSAY MEDIUM
BACTO-PYRIDOXINE ASSAY MEDIUM
BACTO-BIOTIN ASSAY MEDIUM
BACTO-CHOLINE ASSAY MEDIUM
BACTO-CF ASSAY MEDIUM
BACTO-TRYPTOPHANE ASSAY MEDIUM
BACTO-LEUCINE ASSAY MEDIUM
BACTO-METHIONINE ASSAY MEDIUM
BACTO-LYSINE ASSAY MEDIUM
BACTO-ISOLEUCINE ASSAY MEDIUM
BACTO-ARGININE ASSAY MEDIUM
BACTO-TYROSINE ASSAY MEDIUM
BACTO-CYSTINE ASSAY MEDIUM

The *method* employed in carrying stock cultures of the test organisms and preparing the inoculum for microbiological assay is important. The following media have been developed especially for carrying stock cultures and for preparation of the inoculum:

BACTO-MICRO ASSAY CULTURE AGAR
BACTO-MICRO INOCULUM BROTH
BACTO-B_{12} CULTURE AGAR USP
BACTO-B_{12} INOCULUM BROTH USP
BACTO-NEUROSPORA CULTURE AGAR

BACTO-VITAMIN FREE CASAMINO ACIDS, dehydrated, is an acid hydrolysate of vitamin-free casein prepared especially for laboratories investigating microbiological assay of vitamins.

Over 60 years' experience assures UNIFORMITY · STABILITY · ECONOMY

TAS/DO.3

HEATING MANTLES

for the laboratory and for pilot plant

Electrothermal offers the largest range of heating mantles accommodating any size of glass, silica, porcelain or metal vessel.

Constructions available are :

***SERIES M**......... standard aluminium housed mantles.
***SERIES MV**...... "Multimantle", an aluminium housed multi-purpose mantle for use with a range of vessels.
***SERIES MY**...... aluminium housed mantles of simplified design.
***SERIES MJ** ...... all-flexible mantles with the ingenious neck opening.

AVAILABLE FROM ALL LABORATORY SUPPLY HOUSES

Apart from the standard ranges, mantles can be built for special requirements such as for operation :
***in flameproof areas *with inert gas * at high loadings**

Illustration shows 100 and 200 litre Series M mantles with Buxton certified connections in use at the Distillers Co. Ltd.

ORIGINAL RESEARCH AND ITS ENCOURAGEMENT

IN his latest report, Dr. Caryl P. Haskins, president of the Carnegie Institution of Washington, discusses further some of the problems presented to our times by the formidable diversities which characterize scientific effort. In his previous report he was concerned essentially with the challenges to communication and their implications for scientific institutions. In the present report, approaching the problem of innovation from an entirely different angle to Prof. J. Jewkes and his colleagues in "The Sources of Invention", he examines at some length the conditions most favourable to truly original investigation and the measures necessary to ensure that scientific originality continues to flourish in our society.

Once again Dr. Haskins begins with a brilliant and penetrating survey of the nature of scientific advance, which brings out the really vital factors—factors which tend to be over-shadowed by the very magnitude of scientific and technical effort to-day, when in 1958 American industry alone is estimated to be spending eight thousand million dollars on science and technology. These are massive and powerful factors shaping and seeking the opportunities for innovation, but they may not be ultimately the most significant of our time, though Dr. Haskins recognizes that the major revolutions in human thought are largely invisible to those who pass through them. Even the great tangible events that accompany such changes—the scientific conquests, the social upheavals, the political unrest and change—appear at the time largely as a series of striking but disconnected and disrupting events. In the perspective of three centuries, it is not very hard to see how interrelated were the turbulent material changes of the sixteenth and seventeenth centuries with the deeper revolutions of concept which accompanied them, or to realize how often inner revolution was reflected in the more material, more evident external one. We too may, Dr. Haskins suggests, be living in a time of remoulding of basic concepts that will ultimately be as fraught with opportunities for new exploration as was the scientific revolution of the sixteenth century.

Dr. Haskins's emphasis is on this note of opportunity. The greatest of man's advances are made, he maintains, not in the harshness of old necessity, but in the richness of new opportunity. Only to a limited extent does he believe that necessity is the mother of invention. With mankind, as with all living things, grinding hardship to the limit of endurance may be met by sinewy resistance, may lead to extraordinary heightening of old skills, to a marvellous sharpening and extension of well-tried modes of existence, but, in the larger sense, it may evoke little that is really new. "It is against the great and novel challenge, in fresh and unknown gardens of the intellect and spirit, that the mind of man has always found unrecognized powers, has always gleaned strength and courage and capacity to reach new worlds."

Because, therefore, every significant innovation brings new opportunity in its train, and that new opportunity in its turn breeds wider and more encompassing innovation, the very scale of scientific advances in the past few years brings an incomparable richness in opportunity for innovation, almost explosive in its dimensions. The revolutionary developments in nuclear physics and in relativity have made it clear that the succession of physical observations, the building of hypotheses to connect them, the elaborating of results predicted from those hypotheses, and the experimental testing of these results, while still the essential building stones of scientific inquiry, cannot, with only the older logic that has long connected them, comprehend the whole of Nature or be adequate to all the needs of science. A door has been opened on vistas so wide and unfamiliar that we may well be on the brink of a revolution in our notions of the nature of scientific truth itself. We may perhaps come to think of scientific truth primarily as a measure of the communicability and coherence of systems of thought, as a property of interchangeability between observers on one hand, and of scientific propositions between differing situations on the other.

If the old definition of the primary task of science as the search for truth is to retain its essential meaning, Dr. Haskins suggests we could then well say that the highest aim of scientific inquiry is to make knowledge communicable in all possible situations, and that knowledge shall be judged as 'true' by the degree of 'coherence' among such situations. This, of course, is a different aspect of the problem of communication from that discussed in his previous address; but at this point the two addresses are linked, for Dr. Haskins suggests that an essential core of such thinking, the concept of communication and communicability, may become one of the central ideas of science in the years to come, colouring all its concerns, from particle physics to the sciences of life and mind. Some indication that this is recognized can perhaps be traced in the proceedings of the International Conference on Scientific Information held at Washington last November.

It is out of the meeting of those new challenges and the embracing of the opportunities that the intellectual revolution, which Dr. Haskins predicts, will come, and it is because of them that he suggests there has never been a time richer in scientific opportunity. Nevertheless, truly great innovation remains a comparatively rare event, and Dr. Haskins is too wise to believe it can be organized. Even more important and striking is the rare and precious quality of the innovator himself, relative to the comparatively large and ever-growing number of fine minds devoted to science. He suggests that the opportunities for original advance have not been grasped as fully as they might well be, but his analysis is too penetrating for him to be led astray.

Others have also recognized that the intrinsic difficulty of great innovation and the various impediments to its communication are two reasons for its comparative infrequency. Prof. C. F. Carter and Prof. B. R. Williams, in "Industry and Technical Progress", were particularly concerned with means for removing impediments to communication. They also noted that the rate of technical change is limited by the number of good minds which can be brought to bear on the problems of research, of development and of management, and that this number is not capable of indefinite increase. Similarly, Prof. Jewkes and his colleagues, who, in asking the vital question whether Western societies are fully conscious of what they have been doing to themselves recently, come near the point of view of Dr. Haskins when they refer to the rashness of assuming that, because there are more people equipped with technical knowledge employed in research and development, results are bound to emerge, and that the effectiveness of the work of technicians increases when they are employed in the larger organized works.

Dr. Haskins is no less conscious of the law of diminishing returns. The ultimate limiting factor is the inherent rarity of the real innovating mind. We must, he thinks, accept the fact that in any human population there will be only a small proportion of such minds. We are far from certain how small that proportion need be under the best conditions. Those conditions can eliminate waste and frustration though they cannot increase the absolute number, and it is to consideration of the nature of those conditions that Dr. Haskins devotes the later part of his report.

Although our contemporary culture affords opportunities for creativeness probably unrivalled in history, it also has hazards that may likewise be unequalled. One such hazard is inherent in the very structure of thought and philosophy which may crystallize about a field of inquiry, forming more powerful and dangerous barriers to the advance of concept and experiment alike than we ordinarily recognize. Prof. Carter and Prof. Williams concluded their report to the Science and Industry Committee with the observation that it would take much ingenuity by industry and Government to break up the crust of habit and to divert lively and able minds from the places where change is most likely to those where it is most needed ; and Prof. Jewkes comments specifically on the serious danger that institutions will tend with time to grow stiff in outline and rigid in outlook, and on the challenge which genius accordingly presents. He and his colleagues ask indeed whether, even though there now may be more people with the knowledge and training that may be a pre-requisite for invention, they are used in ways which make it less likely that they will invent. Is there truth in the idea that, although the institution is a powerful force in accumulating, preserving, disseminating and projecting, it will normally be weak in its power to originate and will, therefore, carry within itself the seeds of stagnation unless the powers and opportunities of individuals to compete with, resist, challenge, defy and, if necessary, overturn, the institutions can be preserved ? Or, in other words, is the growth of large-scale invention, of government-sponsored research or even of university education likely to reduce innovation by increasing resistance to change. In science, as in politics, the block mind can be a danger.

A. N. Whitehead's belief that the vitality of thought is in adventure is no less impressed on Dr. Haskins. The more elaborate the pattern of a system of thought, the more adequate, the more satisfactory and the more self-consistent it seems, the more difficult it is to transcend and the greater may be the resistance to truly original departures from it. This paradoxical balance between the older thinking and the new, he points out, is the more delicate because it seems inevitable that, although all new scientific concepts must transcend the older matrix from which they arise, if they are to become established and permanent they must also find firm links with it. This dual relation between the new advance and the older structure of knowledge and reasoning from which it springs may be largely responsible for the long interludes of refinement and consolidation, punctuated by shorter periods of explosive revolution, which characterize the history of human thought, and Dr. Haskins illustrates this thesis with examples from the sciences of life and mind.

There are, however, other more practical barriers. Pointing out that the modern world differs profoundly from other centuries in its conscious recognition of the fact—but not always the process—of innovation, he discounts the belief that because we can by organization accelerate the processes of development built upon innovation, we can also organize for greater innovation the creative act itself. Such misconceptions are peculiarly liable to occur in massive and highly organized environments devoted to research and development, and are inherent in the confusion between the processes of scientific research itself and of development, in the uncritical transfer of ideas and techniques from development and production into the field of scientific innovation. Among such misconceptions, too, is the destructive view that the effectiveness of innovation, like that of production, can be doubled simply by doubling the size of the accompanying effort.

Dr. Haskins thus returns to his deeply significant point that, in our own time of unparalleled technical advance, the great innovations are still highly individual, are still associated, at their inception, with a handful of names ; and that accordingly the comparative rarity of the environments most favourable to truly original investigation, their unusual and special character, and the frequent practical impediments to their best development, may impose sharper limitations on the creative potential of a nation than we are inclined to recognize. They provide, for example, a social basis for taking especial care, in the educational system, to encourage the gifted and exceptional individual. Again, climates of research must comprise many and varied elements, some of which are rarely joined in more ordinary situations. Incidentally, we know little as yet about the optimum size of a research group, or the way a group functions in developing new ideas, and the effect on a group and on himself in the group of an outstanding innovator.

Here the importance of understanding and protection is stressed. Since innovation is, and must, always remain a uniquely individual experience, it poses unusual social dangers for the investigator from which he must be adequately shielded—the animosity with which the new, with its threat to current things, must often provoke. Such dangers may not be fatal once the advance is fairly made; the greater risk is that the prospect of such hardships may inhibit the individual capable of great innovation from undertaking it or from fully developing its results. The unexampled richness of opportunity for scientific creativeness in our society enhances the need to analyse most carefully this climate in which true scientific originality best flourishes and to ensure that environments embodying it are adequately provided and conserved.

Dr. Haskins's prescription for institutions assuming these great responsibilities deserves widespread attention, not only from the universities, independent research institutions and professional associations, but also from the research councils and the Advisory Council on Scientific Policy. The most important of their tasks is, of course, the discovery, the encouragement and the adequate training of the outstandingly original investigator, and the fostering of his work. Such institutions must therefore be unusually sensitive to the rare, natively innovating mind, and unusually adept in its discovery. They must possess in high degree the ability to promote and develop the peculiar drive, the special verve and flair, the fine sense of style which great innovations inherently require, and be able to train the innovator of exceptional promise in the company of other gifted investigators already mature and at the height of their powers.

Above all, such institutions need to create unconventional and malleable environments, meeting not merely the different requirements of different workers, but also of the same investigator at various periods of his working life. Besides provision for the long periods of seclusion and introversion that may be essential during periods of highest creativity, Dr. Haskins insists on ample understanding and capacity to shield the worker in this his most vulnerable time from the insistent demands that will surely come to formulate results and conclusions prematurely. Such institutions must also be able to set and apply subtle standards of excellence, judging and rewarding high standards of excellence by more searching criteria than are often superficially accepted. They need teachers of research of the highest quality and in high ratio to those they train, and finally they have the supreme responsibility of communicating rapidly and effectively to workers in fields that may seem far remote, yet may actually be contiguous to those in which the discoveries have been made.

Ideally, Dr. Haskins believes that such institutions should be relatively small and certainly decentralized so far as possible, and in his view both the universities and the research institutions have a part to play. Neither, however, is likely to meet his prescription unless there is a greater awareness that the nation's reserves of men and women capable of advanced training are limited. The higher educational institutions must give much greater attention to this question of quality, and to making the best use of the exceptional individual. Lord James recently pointed out that we still have very little knowledge of the extent of resources in human capacity; but even while that knowledge is being acquired, we should be giving much greater attention to the needs of outstanding ability than is evident, for example, in the questions which Lord Simon put forward for inquiry in a recent issue of *The Universities Quarterly*. That should be a determining factor in considering, for example, the size of a university, the relations between research and teaching, and the size of a research school; and it accentuates the importance of academic autonomy.

Dr. Haskins notes some of the conditions which hinder universities, both in the United States and in Britain, in discharging their responsibilities in discovering and training new generations of investigators in science. In such an expansion as that which is now contemplated, the universities are particularly vulnerable to pressures which hinder the establishment or maintenance of the conditions which are most desirable for the outstanding innovator but which the community can ill afford to supply for the mediocre. To maintain high standards in teaching staff and high ratios of staff to students will not be easy; to supply appropriate conditions for a research school still less easy, even in the absence of any tendency to require an honours student to undertake research whether or not he has the ability or disposition for research or intends to follow such a career. Nor is the training of the exceptionally gifted individual or the great innovator the only responsibility of the universities.

All this points to the need for diversity, and Dr. Haskins is convinced as to the place the research institute can take in discovering and fostering new minds of high promise, of selecting them with discernment, of affording them full training as investigators, and then seeing that their careers can be spent where their talents are most effective. He has in this address directed attention to opportunities and dangers that exist in Britain as well as in the United States, to problems to which urgent attention is demanded both in planning the expansion of universities and colleges of technology and in considering the organization of the whole structure for research. That some of them have of late been disregarded is unhappily only too apparent; but his report presents a challenge which the Government and the universities must accept if Britain is to develop and use effectively its full resources in scientific and technical manpower.

ANATOMY OF A CŒLACANTH

Anatomie de *Latimeria chalumnae*

Par J. Millot et J. Anthony. Tome 1: Squelette, Muscles et Formations de soutien. Pp. i+122+80 planches. (Paris: Éditions du Centre National de la Recherche Scientifique, 1958.) 9,800 francs.

If we have had long to wait for the detailed account of the anatomy of *Latimeria*, at least the first instalment handsomely justifies the gestation-period. It is, moreover, the part which will be of greatest interest to palæontologists, who have so patiently and skilfully unravelled the structure of the long-extinct relatives of this anachronistic fish. There is an æsthetic pleasure in seeing how, in detail after detail, *Latimeria* takes its place in the evolutionary pattern already outlined by the study of the difficult fossil material. There are some surprises. The nature of the rostral organ and the lack of relationship between the endocranial cast and the shape of the brain have been dealt with in earlier papers, though it must be said that palæontologists have been cautious in their claims for such casts. The pectoral girdle was not well known in any fossil and it proves to have no skeletal connexion with the head. The urohyal has both endochondral and dermal components. Some arguments have been settled; for example, a cavity which in a fossil Stensiö interpreted as lodging the fixed end of the eye-muscles turns out to be occupied by cartilage, as Watson surmised, and the eye-muscles excavate no myodome.

The general structure of the head had been outlined in an earlier paper, but now a series of photographs of dissections and of sagittal, parasagittal and transverse sections, each with its explanatory diagram alongside, makes every detail clear. We see the structure of the intracranial hinge; the pair of apophyses of the anterior half sliding in long oblique grooves in the posterior half; and the pair of huge subcranial muscles bulging the lining of the roof of the bucco-pharynx. These last originate on the base of the prootic mass and are inserted by broad aponeuroses on the sides of the parasphenoid, and must restore the two parts of the cranium to the position in which the apophyses of the hinge lie at rest in their sockets at the tops of the grooves. They recall the forward extension of the hypaxial body-muscles of the teleost *Chauliodus* (Tchernavin, V. V., 1953, and Günther, K., and Deckert, K., 1955). In *Chauliodus* the hinge lies between the occiput and the modified anterior vertebral region and is, of course, not intracranial, but, as in *Latimeria*, it is at the anterior limit of the persistent notochord. In *Chauliodus* the whole neurocranium is moved down and up by the subcranial extension of the hypaxial muscles and their antagonists the epaxial muscles, which send aponeuroses forward on to the cranial roof and act in conjunction with the complicated apparatus which opens the mouth. Millot and Anthony have searched in vain for a simple antagonist to the subcranial muscles, for there is in *Latimeria* no dorsal extension of the epaxial muscle or its tendons on to the anterior cranial half. They find an indirect antagonist, however, in the coraco-mandibular muscle, which lowers the mandible and at the same time transmits its force through the palatoquadrate arch to push the front of the cranium upwards and forwards, so that the hinge-apophyses slide forwards and downwards in their grooves. From Fig. 20 and others it would seem that this might be reinforced by the upward push of the hind end of the lower jaw on the symplectic, which (as in *Amia*) articulates with it behind the quadrate, on which the mandible is pivoted. In advanced teleost fishes, where processes of the premaxillaries slide upon the ethmoid, the upper jaw moves forwards relative to the cranium instead of the fore-cranium to the hind-cranium. In this action the fibrous skin of the lip plays a part, and this may be so in *Latimeria*, too.

More than the functional analogies and contrasts, however, most vertebrate zoologists will look for the deployment of the basic vertebrate morphology in the sixth of the main vertebrate evolutionary lines which were already recognizable in the Devonian, and which survive to-day as Selachii, Holocephali, Actinopterygii, Dipnoi, Tetrapoda and *Latimeria*. A feast is spread for us in this field, of which no reviewer's sample can give an adequate idea.

Great interest is attached to the paired and median pediculate fins. Any hope that the paired fins might conform to the theoretical (and rhipidistian) precursor of the limbs of land vertebrates is soon dispelled. Not only is there nothing to compare with the radius and ulna (or tibia and fibula), but the pectoral girdle provides the apophysis, and the basal joint of the fin-lobe the socket, for the pectoral fin-joint, instead of vice versa as might have been expected. This is one of several features which underline the early separation of the cœlacanth stock from the rhipidistian.

The fin-rays, called lepidotrichia by the authors, are not exactly like actinopterygian lepidotrichia, being forked only at their bases and single for the greater part of their length (although one would like to see this confirmed by a transverse section). The dorsal and ventral lobes of the 'caudal fin' have radial supports and only the rays of the terminal lobe conform to the restricted definition of a caudal fin in articulating directly with the neural and hæmal arches, here much reduced and, of course, not broadened into hypurals.

Le Centre National de la Recherche Scientifique has given this book an unusual form worthy of its unusual subject. The volume is first opened in the middle and the pages of each half are hinged along the top, so that the reader can have a two-column page of text on the left, and on the right can turn to any plate with its accompanying explanatory diagram. The photographers, radiographer and draughtsmen have done a magnificent job and we have nothing but gratitude and admiration for the authors, both busy men whose normal occupations had to be continued while they explored this precious material and made themselves familiar with the literature in a field which was hitherto the speciality of neither of them.

The price will strain most private purses and may well make librarians blench, but buyers may be assured of good value and should then start saving for the next volume. E. Trewavas

CHEMISTRY IN SCHOOLS

The Teaching of Chemistry

By N. F. Newbury. Second edition, completely revised and reset. Pp. xv+294. (London: William Heinemann, Ltd., 1958.) 21*s*. net.

This book is designed to help the young chemistry master in his first appointment, and also to help teachers-in-training; it is a very practical book, full of detailed advice. The book is intended to cover the whole range of ages up to the university. The author, who is director of education of St. Helens, has clearly spent much time and effort in studying and collecting the views of many science masters and this book represents the fruit of his labours.

The first two chapters, it is true, represent an excursion into higher regions; but the rest of the book is very much down-to-earth. The third chapter suggests detailed syllabuses for elementary and advanced courses; the fourth gives a mass of advice to the new master, starting on his first appointment; the fifth discusses in great detail the practical organization of a school laboratory, the type of equipment required (including the scope of improvized and home-made apparatus), laboratory rules, and safety precautions; Chapter 6 discusses the roles of individual laboratory work by pupils and practical demonstrations by the teacher; Chapter 7 gives useful advice on teaching quantitative methods; Chapter 8 deals with small-scale methods, again with detailed instructions for improvizing equipment cheaply; Chapter 9 deals with the teaching of chemical theory, with special reference to the introduction of chemical formulæ; Chapter 10 discusses problems of scientific language and terminology and with teaching pupils to take notes; Chapter 11 deals with the use of diagrams and visual aids, including models, films, and useful advice on sources of educational films; Chapter 12 discusses the teaching of experimental technique; and the final chapters suggest ways in which chemistry courses can be adapted to local conditions, the role of school clubs and visits, and the organization of a school science library.

This is a very mixed book. It contains a great deal of useful information, set out in a disjointed and incoherent form, and one gets the impression that the author has relied more on the experience of others than his own. The chapters on practical work contain detailed accounts of apparatus and experiments, but very little on the kind of problems that actually arise in teaching practical chemistry. The theoretical syllabuses seem old-fashioned and unrealistic; for example, the author would defer any discussion of chemical formulæ and equations until half-way through the third year of the course.

In short, although this book would be useful to a critical reader, it could prove misleading to a young science master who had no other guide.

M. J. S. DEWAR

PHILOSOPHICAL PSYCHOLOGY

The Concept of Motivation

By Dr. R. S. Peters. (Studies in Philosophical Psychology.) Pp. viii + 166. (London: Routledge and Kegan Paul, Ltd.; New York: Humanities Press, 1958.) 14*s*. net.

DR. PETERS's book on motivation is the fourth volume to appear in the Routledge "Studies in Philosophical Psychology" which commenced publication in 1957. Dr. Peters describes his book as "a missionary enterprise", and it is designed to show psychologists that their theories of motivation are muddled, that any over-all theory of motivation is an impossibility, and indeed further that any attempt to construct a systematic and comprehensive science of psychology is not merely premature but also logically indefensible.

Let it be said at once that Dr. Peters is far more deserving of a sympathetic hearing than most philosophical critics of psychology, simply because he knows much more psychology than is usually the case. He has read the literature of psychology widely and acutely. His detailed criticisms of particular theories are worthy of attention, though he tends to take these theories much more seriously than psychologists themselves. Instead of regarding them as moves in a game, none of them as yet final, he takes them rather as *ex cathedra* pronouncements, and speaks of "the established order in psychology". There is, of course, no such thing as an established order in psychology, and no establishment among psychologists. Psychology is a branch of scientific inquiry, not an orthodox creed. In subtle ways like this Dr. Peters shows that in spite of his extensive knowledge he is in fact a touch-line observer and not himself a player.

The point over which psychologists will want to take issue, however, is not the detailed criticism of current theories, but the contention that the attempt to construct a systematic theory of motivation is in principle wrong. Here Dr. Peters is not likely to make many converts and his missionary enterprise is likely to fail. For one thing, criticisms of this kind are far from new. The gist of what Dr. Peters says was said many years ago by Socrates in answer to Anaxagoras (Plato, "Phaedo", 97*B*–99*D*). It has been repeated by philosophers, particularly those of an idealistic complexion, throughout the ages. It is unlikely that Dr. Peters will convince where his distinguished predecessors have failed to do so.

Basically the reason for this is that in starting point and in methodology Dr. Peters and the psychologist are far removed from each other. Dr. Peters believes that we "already know too much about human behaviour". His interest in human nature is moral and practical. If he can give an obvious practical answer to the question 'Why does Mr. *A* do *X* ?', Dr. Peters is satisfied and regards further explanation as 'otiose'. What Dr. Peters lacks is scientific curiosity, the desire to probe beneath the surface of the familiar and conventional. He does not see that in fact even everyday human actions are mysterious and remarkable performances. For it is, of course, wholly untrue that we know too much about human behaviour in any acceptable scientific sense. We know scarcely more than primitive pre-scientific man knew about the physical universe. It is this belief, which Dr. Peters shares with other philosophers, that human behaviour is, as Ryle put it, "relatively easy to understand", which places a wide gulf between the philosophic critic and the psychologist.

Secondly, in his method of approach Dr. Peters is fundamentally verbal. What is needed in psychology, he maintains, is conceptual analysis rather than research (p. 141). He is all the time concerned with "sorts of question" and "linguistic usages"; he is not really interested in the functioning of behaviour as such. One constantly feels the spiritual gulf between this method of approach and that of the psychologist, the difference between a concern for words and a concern for matters of fact.

Finally, there is Dr. Peters's own brand of dogmatism, his unhesitating assumption that nature and 'convention' belong to two different realms, and that because human behaviour is essentially 'conventional' (that is to say, conforming to social standards and rules) it cannot be explained in the language of natural science. But the assumption that nature and convention can never be embraced in a unitary explanatory scheme is a gratuitous one, and by no means logically necessary as Dr. Peters claims. All that can be said is that certain kinds of scientific explanation are incompatible with goal-seeking and rule-following. Science, however, is not, as Dr. Peters seems to suppose, tied down to any particular form of explanatory model. Perhaps more promising than either the dogmatic dualism to which Dr. Peters himself adheres, or the mechanical monism which he criticizes, is an emergence theory which allows for the development of novel organizational levels, but sees these as fundamentally rooted in a common natural world. L. S. HEARNSHAW

PROGRESS IN VITAMIN AND HORMONE RESEARCH

Vitamins and Hormones

Advances in Research and Applications, Vol. 15. Edited by Prof. Robert S. Harris, Prof. G. F. Marrian and Prof. Kenneth V. Thimann. Pp. xi+355. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1957.) 9.50 dollars.

IT might have been expected that vitamins and hormones could not remain easy bed-fellows indefinitely, but for fifteen annual volumes there has been no sign of discord. It is perhaps natural that vitamins or nutritional problems often take precedence over hormonal ones in these annual volumes, but in the one under review an equal distribution of articles between the two fields of study has been achieved. Three of the articles are on vitamins and related substances, three are on hormones, one is concerned with both vitamins and hormones, and the remaining one, on the biosynthesis of cholesterol, is relevant to both fields of study in so far as cholesterol is a precursor both of steroid hormones and of vitamins D.

The first article, by A. W. Johnson and Sir Alexander Todd on the "Chemistry of Vitamin B_{12}", includes not only an account of the research on the isolation, structure, and chemical and physical properties of the vitamin and of substances related to it, but also a discussion of the biosynthesis of vitamin B_{12} and related substances and the chemical determination thereof. "Total Syntheses of Carotenoids" are discussed by O. Isler and P. Zeller in an article which is a masterly chemical condensation. The metabolic importance of carnitine, a subject reviewed by G. Fraenkel and S. Friedman, which since 1952 has been recognized as an insect growth factor, is still not clear, but the relevant information is ably surveyed. In "The Biological Synthesis of Cholesterol", Konrad Bloch considers a subject to which he himself has made most important contributions and which now lends itself to a chemically co-ordinated treatment which is largely based on research of the past ten years. With "Adrenaline and Noradrenaline", J. H. Gaddum and M. Holzbauer deal with a subject in which interest is rapidly growing in many respects, not least with regard to the possible effects of the central nervous system, but the article concerns itself largely with the better known experimental work on this most interesting pair of substances. R. C. de Bodo and N. Altszuler consider "The Metabolic Effects of Growth Hormone and Their Physiological Significance", while "Steroids in Human Blood" (R. Borth) deals with methods and with the interpretation of results in an orderly fashion. Finally, in surveying the "Influence of Hormones, Vitamins, and Other Dietary Factors upon the Formation of Bone, Dentine, and Enamel", J. T. Irving has brought together much information that would not be easily obtained otherwise within the covers of a single article.

The editors aim at making this publication international in its authorship and authoritative in its statements. In this volume they have clearly achieved both these aims. F. G. YOUNG

J. L. W. THUDICHUM

Thudichum

Chemist of the Brain. By Prof. David L. Drabkin. Pp. 309. (Philadelphia, Pa.: University of Pennsylvania Press; London: Oxford University Press, 1958.) 40s. net.

THUDICHUM, born in 1829 in Büdingen in the Grand Duchy of Hesse, studied medicine in Giessen, where he came under the influence of Liebig. Soon after graduating, he emigrated to London, probably for political reasons, and built up a successful medical practice. He was a very remarkable man of wide scientific and artistic interests and was possessed of an unfailing energy. He wrote on many medical and other subjects, ranging from books on the pathology of urine, the treatment of nasal polypi, and the origin, nature and variety of wine, to his master work, unacknowledged during his life-time, on the chemical constitution of the brain.

Prof. D. L. Drabkin's interest in Thudichum dates from 1924 when he worked on the urinary pigment urochrome, first so named by Thudichum. In the following thirty years he collected probably all the information available about Thudichum; thus, when invited to give four lectures on Thudichum in 1954, he set himself the task of finding the reasons for the lack of recognition of a man who is now generally acclaimed as one of the pioneers in the field of brain chemistry. The answer is not a simple one. The circumstances in which Thudichum carried out the greater part of his work, in a laboratory in his home, were highly unorthodox. The expenses were met from Government grants and later from the income of his lucrative practice. The results he obtained differed in important aspects from those of his contemporaries and he became involved in polemics which were violent even by nineteenth century standards, thus making powerful enemies. His versatility and large literary output led to the quite unjust charge of dilettantism and, what was worse, the integrity of his work was doubted. This and other evidence convinced Prof. Drabkin of the existence of a conspiracy against Thudichum.

The three main chapters of the book: the man, his times and contemporaries, and his works, make interesting reading although the rather expansive style and the inclusion of not strictly relevant material may not be to everyone's liking. The book, besides being liberally illustrated with 'Thudichumiana', is well documented with references, biographical details, a bibliography, transcriptions of letters, etc. (82 pages). Thus it gives a good deal of information for students of the early history of biochemistry and also contributes to the difficult problem of what constitutes a climate of opinion sufficiently receptive to give recognition to the work of a pioneer.

H. W. KOSTERLITZ

FUSION OF HEAVY HYDROGEN*

By Dr. T. E. ALLIBONE, F.R.S.

Associated Electrical Industries, Ltd., Aldermaston

'GENEVA' has come and gone, leaving in its trail a huge mass of printed papers that will keep scientists occupied for a long time to come. The research on fusion of deuterium has been secret for eight years; but now we can see the whole vista of thermonuclear research in many countries as revealed at Geneva in 1958, and in a short space I will try to present this vast subject as it might be seen if looked at down the wrong end of a telescope. The subject will not be dealt with chronologically, nor can all the investigators be mentioned by name in the space available.

All we are trying to do is to heat deuterium or heavy hydrogen to a temperature of many million degrees and keep it at this temperature; if one can do this the nuclei will, from time to time, coalesce or fuse together in several different ways, each reaction liberating much energy. Thus, two deuterium nuclei can form tritium and a proton; or can form helium-3 and a neutron. The tritium, fusing with deuterium, can form helium-4 and a neutron; the helium-3 and deuterium can form helium-4 and a proton. In all these reactions the released energy will be given to the two particles formed in the discharge, which will, in consequence, repel one another with high velocity. In total, as much energy would be released by the *fusion* of 1 gm. of hydrogen as would be released by the *fission* of 3·5 gm. of uranium, and by the burning of 10 tons of coal. In such a fusion reaction 40 per cent of all the energy released is given to neutrons and they would almost certainly escape from any vessel containing the hot gas; 60 per cent is given to the charged particles which might, or might not, escape according to the circumstances of the experiment.

The deuterium – tritium reaction proceeds at a lower temperature than the deuterium – deuterium reaction, but, though there is plenty of deuterium in the ocean, tritium does not exist in Nature, and is made in an atomic fission reactor. Actually, the neutrons escaping from a deuterium – deuterium or deuterium – tritium reaction could be absorbed in a blanket of beryllium, which dissociates to yield two neutrons for every neutron absorbed, and these in turn could be absorbed in lithium, which then dissociates to tritium, so there is a chance of breeding more tritium than is consumed in the fusion reaction. In the long run, therefore, the fusion reactor of the future may operate on the deuterium – tritium reaction.

A hot gas, like any other hot body, can lose heat by radiation, by conduction, and by convection; so the achievement of a given temperature is set by the balance between the rate of loss of energy by these three processes and the rate of gain of energy, either from an external source or from the release of nuclear energy when the deuterium atoms fuse together. Fortunately, the rate of release of energy by fusion rises extremely rapidly with temperature; for example, if the temperature is increased from 10^6 to 10^7 degrees the rate of fusion increases by 10^8, and a further rise of temperature to 10^8 degrees increases the rise of fusion by a further 10^4, whereas the energy radiated by the gas only increases as the square root of the temperature. This is indeed fortunate, because there is nothing we can do to stop energy being radiated from the gas. The other losses, convection and conduction, would occur if the hot gas actually came in contact with the walls of the containing vessel; but it is generally assumed that this must be prevented at all costs, since the gas temperature is so very high compared with the melting points of all metals that if the hot gas bombarded the walls anywhere the walls would evaporate, and would introduce impurities into the gas. These impurities cannot be tolerated, for their presence in the gas would immediately lead to a rapid increase in the amount of heat radiated. It has been calculated that the break-even temperature of the reaction, that is, where the total energy released by fusion just exceeds the total energy fed into the discharge, is about a hundred million degrees, which is a few times hotter than the centre of the Sun and many thousand times hotter than the surface of the Sun.

At these temperatures the atoms are colliding with one another with such high speed that all the electrons are knocked off the light elements. In the case of hydrogen (or deuterium) all atoms will be dissociated, there will be as many electrons as there are hydrogen nuclei and we call this mixture a plasma. It is electrically neutral, being made up of an equal number of opposite charges. If the plasma is in a magnetic field the charged particles can move freely down a magnetic line of force; but if they have any component of velocity perpendicular to the magnetic field they will describe circles around the lines of force, or spirals if they are drifting down the line. Positive nuclei having a larger mass than electrons will describe larger orbits than electrons having the same energy.

The method used by nearly all investigators to keep the hot gas from touching the walls of the vessel depends on the force exerted by the self-magnetic field of a current, and this force will cause the current to pinch away from the walls of the vessel until the inward force is balanced by the outward pressure of the gas. The first recorded photograph of a discharge pinched due to its own magnetic field is due to Ware and Cousins. A current of many thousands of amperes was discharged through a gas in a toroidal vessel, and in a few microseconds the discharge had pinched to a small diameter, and having contracted beyond its equilibrium it 'bounced' out again and contracted and expanded several times, thus exhibiting a form of instability. When the current was maintained for some hundreds of microseconds, the discharge already pinched to a narrow diameter moved rapidly about in the discharge vessel—we speak of this as 'wriggling'—striking the walls, and with currents of 10^5 amperes severe volatilization of the metal walls of a large torus vessel occurred.

The explanation of these instabilities is not hard to follow in general terms; in the case of 'pinch instability' any geometrical irregularity of the vessel can cause a slightly higher localized self-magnetic field which, acting on the current in the discharge, will compress the gas more than elsewhere, and so a localized pinch will develop; in the case of 'wriggle instability' any slight departure from a perfectly linear discharge will cause a bunching of the lines of force on the inner radius of any small bulge so formed and force the discharge to bulge farther off the axis.

---

* Substance of a Friday Evening Discourse delivered at the Royal Institution on December 12.

A few years ago investigators in several laboratories detected bursts of neutrons emitted for fractions of a μsec. and naturally suspected that they had achieved very high temperatures; but all of them ultimately found that the neutrons arose from the collisions of a few deuterium ions endowed with far more energy than the mean energy of the gas, and proved that the very act of over-pinching at localized points created high local electric fields across which a few ions were accelerated to high energy and that these fast ions were responsible for the deuterium–deuterium reactions.

Theory indicated that if a constant magnetic field were set up in the discharge vessel parallel to the axis of the discharge then the lines of force of this field would, in a sense, stiffen the discharge and prevent in some circumstances both the pinch instability and the wriggle instability. A succession of photographs, each lasting a half μsec., were taken of a discharge in a cylindrical vessel, the records being made every half μsec. In the absence of an applied axial magnetic field the discharge was observed to pinch rapidly, but in 4 μsec. it became unstable and lashed about in the vessel. As the value of the magnetic field was increased, the rate of contraction of the pinch was reduced; but the onset of wriggle instability was postponed. Without the field neutrons were observed at the moments of minimum contraction, but as the field was increased the number of neutrons detected diminished. Presumably the spurious accelerating mechanisms which previously produced neutrons do not operate in a relatively stable gas column.

Straight discharge tubes will ultimately suffer from the fact that they must have electrodes at each end, and therefore after some μsec. of operation the gas discharge will heat these electrodes and evaporate them to some degree and so introduce impurity atoms into the gas. Nevertheless, many investigators in several countries are still building new apparatus having this simple cylindrical geometry, in order to study further how to stabilize a discharge to keep it from striking the walls. In one case, in order to minimize end effects, a new tube has been made 20 ft. in length, 6 in. in diameter, and in this a new peculiar form of large-amplitude rotational instability has recently been found. In another recently constructed straight tube the discharge is in the form of a hollow cylinder between annular electrodes at each end of the tube, but the return current passes up both an inner and an outer copper cylinder (hence the name *Triax* for this tube). The return currents flowing in each metal cylinder produce two oppositely directed magnetic fields, in the space between which the gas is squeezed into a thin sheath which has most remarkably stable properties.

In Britain twelve years ago, when this kind of work was begun, the avoidance of end-electrode effects was regarded as imperative, so almost the whole of the development in Britain has centred on toroidal geometry. In early records of the discharge in glass toroidal vessels which we operated in Aldermaston, the discharge was photographed with exposures of 1 μsec. duration at various times up to 400 μsec. after initiation of the discharge. For many μsec. the discharge is pinched to a relatively stable narrow toroidal beam and then the sideways wriggles develop over the following few hundred μsec. If a solenoidal winding is placed around the torus and current passed through it to create a strong field down the axis of the vessel, then the discharge is rendered much more stable by the field of the solenoid. It pinches away from the walls of the tube as the current rises in the gas and occupies the central region of the vessel for relatively long periods of time. When the discharge tube is very clean, the amount of light from the discharge is feeble; but it is possible to take photographic records of the very highly ionized atoms of oxygen which are always present there as an impurity, oxygen atoms which have been stripped of four of their eight electrons. The distribution of the light intensity in spectrum lines of quadruply ionized oxygen atoms has been determined over the diameter of the torus, taking such records at different times from the beginning of the discharge, and it is found that the highly ionized oxygen atoms remain reasonably well centred on the axis of one of the torus tubes constructed in Aldermaston (*Sceptre III*) for 600 μsec.

Neutrons have been produced in the past year in several toroidal vessels, in *Zeta* at Harwell and *Sceptre* at Aldermaston in England, in the apparatus called *Perhapsatron* at Los Alamos, and in the copy of our apparatus built by the Russians in 1958. The first point of interest to note is that the durations of reasonably stable discharges in toroidal vessels have been far longer than in linear vessels, lasting up to, for example, several milliseconds, and neutrons are emitted through a large fraction of the whole current pulse. It is very natural to think, therefore, that as the violent motions of the discharge have been prevented by the externally applied magnetic field the temperature of the gas might have risen to a high enough value for a true thermonuclear reaction to have occurred. We can get some idea of the temperature of the gas by examining one of the spectrum lines of highly ionized impurity oxygen gas in a high-resolution spectrograph and comparing it with a normal spectrum line of nearly the same wave-length emitted by some atoms. The oxygen line is found to be far broader, signifying that the atoms of oxygen in the vessel are approaching or receding from the recording apparatus with high velocity—so-called 'Doppler broadening' of the spectrum line; from this an estimate of the temperature of the gas can be made. This comes out at several million degrees, and at this temperature we might expect a large number of deuterium collisions yielding neutrons and protons. If the gas is all at this temperature the neutrons and protons will be emitted equally in all directions and will have an energy of 3 MeV.; if, however, most of the gas is at a lower temperature but a few of the deuterium ions have, for some reason or other, a high velocity in the general direction of the discharge, then neutrons and protons emitted from fusion of these fast ions will travel faster in the forward direction of the discharge than in the reverse direction. In Aldermaston we looked for protons coming out of the tube in two directions, at 30° and at 150°, to the direction of the positive-ion gas current. Those coming out in the forward direction were found to have slightly more energy than those coming out in the reverse direction, indicating that the centre of mass of the deuterium–deuterium ions which collide to yield the protons is moving in the direction of the ion current with a speed well in excess of the mean velocity. It therefore looks as though the ion velocities are not truly randomized but that a few are going faster than expected, and therefore the reaction cannot be described as truly 'thermonuclear'. All investigators working on toroidal discharges reported agreement on this point at Geneva. The really surprising feature of the measurements is that the temperature is as low as it is, for the amount of energy being fed into the discharge from the condensers is far higher than is necessary merely to heat the gas to a few million degrees, and we are seeking to explain how some of the energy is being lost.

An entirely new concept for the containment of a gas at a temperature of millions of degrees is offered to us by scientists at the Livermore Laboratory, in California, the so-called 'mirror machine' principle. It will be recalled that a charged particle having a given velocity can travel along a magnetic field relatively easily but cannot travel across such a field in normal circumstances. If two strong magnetic fields are imposed locally at the ends of a straight discharge tube, the lines of force here are crowded together, and positive and negative ions travelling along the lines of force between the strong fields are trapped as though in the neck of a bottle and cannot easily escape, most of them being turned back on themselves; it must be noted, however, that ions travelling exactly on the axis, and indeed just at a small angle to the axis, can escape from the ends of the 'bottle'. As the strength of the mirror magnetic field is increased so the ions are turned back at an earlier stage and thus are confined to a smaller volume.

One difficult problem with mirror machines is associated with the injection of charged particles into the magnetic bottle; any particle injected through the end of the bottle on the axis will be turned around by the field at the far end of the bottle and emerge the same way that it went in. To avoid this emergence, it is necessary to change the magnetic field while the ion is still inside the bottle, that is to say, ions can be shot in and kept in only when the field is actually being increased; and as the field is increased they will be compressed into a smaller volume. Another way is to inject the beam from a source already inside the magnetic bottle, but again, if the field does not change after injection, the beam, in due course, after a number of rotations around the vessel, will strike the source; this too can be avoided, however, if the field is increased after injection of the ions. A very attractive feature of internal injection is that the beam can be initially injected with very high ion energy corresponding to a temperature of thousands of millions of degrees. This energy it shares with other ions in the chamber, and the main role of magnetic compression becomes one of containing the ions, not of increasing their temperature.

In the early research at Livermore on magnetic mirrors four years ago, it was found that shock waves could be generated in the gas by applying a magnetic field which rose extremely rapidly to high values. Very recently, a group working in Los Alamos has extended this work and has produced extremely high temperatures by shock heating. When currents are suddenly passed through two adjacent short solenoids mounted on the same axis, large currents are induced in the gas flowing in the opposite direction. The current in the coil repels the current in the gas, thus driving the ionized gas to the axis of the coil, and two shock waves are generated which will meet one another between the coils, giving a region of maximum compression. If, in addition, the magnetic field in each coil continues to rise, the gas between them will be further compressed. In the most recent work at Los Alamos the shock compression of the gas occurs within 0·2 μsec. and maximum compression of the gas between the mirrors is reached in 1·5 μsec. Neutrons have been emitted at the peak of the compression, so that it is thought that in this very short time the temperature of deuterium has been uniformly raised high enough to yield a true thermonuclear reaction. However, more work will be necessary to establish that this is so.

In everything described so far, the duration of the experiment has been very short, from a μsec. or two for the shock excitation, hundreds of μsec. for the mirror compression machine, and a few msec. for the largest of the toroidal discharges, and it is not easy to see how such experiments could lead to useful thermonuclear power reactors. They are essentially steps along the way. One or two very recent developments have been described which might in the long run become the prototype of nuclear fusion power-producing reactors, because if successful they might be able to operate continuously. The first of these was developed at Oak Ridge in America, called the *D.C.X.* machine, and we learned at Geneva that the Russians had developed a slightly different version of this known as *Ogra*.

Scientists in Oak Ridge have tackled the problem of supplying energy to the plasma of deuterium ions and electrons in a radial fashion. Instead of developing a transient magnetic field rising rapidly to compress and heat the ions, or, as in the Livermore mirror machines, to contain energetic ions injected into the machine at low magnetic field strengths, they believe that a steady-state device can be made to hold the plasma while energy is fed in electrically from outside. A 'magnetic bottle' of high intensity is set up in a cylindrical chamber to prevent any ions from escaping at its ends. Then into the chamber, at right angles to the lines of magnetic force, is directed a beam of singly charged molecules of deuterium accelerated to about 600,000 volts in a discharge tube. These ions have so much energy that there is no need to give them more by magnetic compression when inside the bottle. They are deflected by the magnetic field into a circular orbit; but after a short distance the beam is fired across a carbon arc extending along the lines of magnetic force between two electrodes. As the deuterium molecule goes through the arc there is a very high probability that it will be split up into a deuterium nucleus and a neutral atom of deuterium. The latter, being neutral, escapes; the deuterium nucleus, however, is deflected into circular orbit of smaller radius by the magnetic field, and continues to rotate in this orbit wholly within the vessel, ionizing residual gas by colliding with deuterium nuclei, the temperature of which is thus raised. If this process continued long enough and if losses could be kept down, then the temperature of the whole of the deuterium in the bottle would slowly rise until nuclear fusion begins.

Russian scientists described the apparatus known as *Ogra* at Geneva—it seems to be a copy of *D.C.X.*—but they had not fallen upon the rather nice idea of using a carbon arc to dissociate the deuterium molecular ion. Instead, in this apparatus the molecule must be dissociated by chance collisions with deuterium atoms and, in consequence of this, the apparatus has to be much longer than the American *D.C.X.* machine to guarantee that the deuterium molecule is dissociated and does not escape.

The American and Russian devices have not been working very long, and there are some obvious difficulties, the most important of which is a large loss of beam by what is known as the 'charge exchange mechanism'. If the energetic deuterium ion collides with a neutral atom of gas and picks up an electron from it, thus becoming a neutral atom itself, it will no longer be confined by the magnetic field and it will carry out of the apparatus much of the energy with which it was originally endowed. To reduce this, the pressure in the vacuum chamber must be as low as possible, and the current in the positive ion beam must be as high as possible to make good whatever loss there is. Nevertheless, particles have been trapped by the magnetic field and held in the vessel for many msec., and there are great expectations that high temperatures will soon be reached in the gas.

The second development which might become very important as a power producer also comes from America, the work of Prof. L. Spitzer and his team at Princeton, called the *Stellarator*. Several versions of this have been built in the past seven years, and at Geneva the plans for a very large version due to be completed in 1960 were described. Prof. Spitzer's goal from the first has been to confine the plasma for a very long time. Clearly a straight tube is no good for this purpose because of end-effects already described. Even if we turn a straight tube into a torus and attempt to confine the plasma by a magnetic field around the torus we shall lose particles in the long run for a very important reason: the positive and negative ions will drift apart in opposite directions across a cross-section of the torus. This arises because the field of a solenoid wound on a torus is stronger on the inner side of the torus than on the outer, so an ion is deflected through a smaller radius in the region of higher field than in the weaker part of the field. If it is travelling down the torus its orbit is not, therefore, a closed spiral, but a slowly drifting spiral, drifting upwards for positive charges; downwards for negative charges. Prof. Spitzer was able to correct this by twisting the torus into a figure of eight so that ions having drifted apart on one side drift back again on the other. Temperatures of a million degrees have been reached with the beam well confined for a long time by the *Stellarator* field. In later versions of this apparatus the twisting of the torus has been eliminated by applying a further set of windings over the torus to produce cusped fields which have the effect of cancelling out the drift motions of the ions.

To reach higher temperatures a system of magnetic pumping has been developed at Princeton; it consists of a localized pulsating magnetic field driven at radio-frequency, compressing and expanding the plasma locally as the plasma is driven by an electric field through the pump. Such an alternate compression and expansion would produce no net gain of heat in the gas if it were not for a phase-lag which occurs between the increase in density of the gas and the increase of temperature. A full theory of this complex problem has been developed to determine the correct frequency at which to pump; but experiments have not yet verified this theory.

The final point of importance to make about the *Stellarator* is that it incorporates a neat way of removing impurities from the vessel; this is probably essential if the gas is to reach very high temperatures. The device consists of a localized magnetic field of complex shape which strongly influences the lines of force at the edge of the torus, bending them outwards, but does not influence those in the central region. Heavy impurity ions leaving the walls of the vessel will, on the first time around the torus, be deflected and trapped in this 'diverter' field; whereas the hydrogen ions and electrons in the central regions of the torus will be uninfluenced and will not be lost to the diverter.

Finally, there is yet another device which shows great ingenuity and promise, the so-called 'homopolar plasma accelerator'. In this a magnetic field is directed parallel to the axis of a flat annular plate of ionized gas and is shaped to give mirror geometry to keep the plasma from escaping out of the annular space at the 'edge' of the plate. Between a cylindrical electrode on the inside of the annular plate and a cylindrical electrode on the outside of the plate is established an electrical field which, in the absence of the magnetic field, would cause current to flow radially outwards through the plate from cylinder to cylinder. But because of the magnetic field the plasma is forced to move at right angles to the electric and magnetic field; the plate therefore rotates like a flywheel about the central axis of the device, and the energy given to the flywheel ultimately appears as heat in the gas due to turbulent mixing within the flywheel. Containment times have been very satisfactory and fairly high temperatures have been recorded, but the device is a very recent development and much remains to be learnt about the physics of such rotating plasmas.

I seem to have listed a great many approaches to the same ultimate goal. Now that the cloak of secrecy has been removed, we see that in the United States and the U.S.S.R. a far greater effort has been put into this problem than in Great Britain. We know that in neither of those countries is there a shortage of fuel, nor need for speed of development of a fusion reactor—nor is there real justification for speed in Britain in the same sense that the fission development had to proceed to help solve our fuel problem. In Britain we have pursued almost only the toroidal approach. This does not necessarily mean that we have backed a 'wrong horse'; we have only backed one horse. The Russian scientist, Artsimovich, summed up the situation as he sees it in the U.S.S.R., where many different kinds of experiments are in progress: "So far not a single one of the ideas regarding controlled fusion reaction is decisively superior to any other, and therefore investigations in the near future must be carried out in many diverse directions".

Edward Teller's opinion is that it will be several more years before a machine can be constructed that produces more energy than it actually consumes. I should say it will be a year or two at least before we even see how to construct such a machine, knowing that it will work when constructed, for we have not yet reached containment for times long enough, nor have we devised systems which keep clean long enough, nor do we yet understand the way by which some of the energy is lost. In fact, at this moment we really have no justification for believing that the ultimate problem will be solved; it might be that we shall never achieve satisfactory containment; it might be that the radiated power will be of such surface density that evaporation of impurities from the walls will beat us; it might be that the reaction will have such a positive temperature coefficient that it will go off with explosive violence; all we can say at present is that we now have a fair measure of the difficulties, and with incurable optimism we believe we should spend money on the research because we have an inner conviction of success which will come in time.

Edward Teller and Artsimovich also mentioned the use of thermonuclear explosions to achieve peaceful objectives, such as rock crushing, mining, and huge earth-moving jobs. The fuel is extremely cheap compared with conventional fuel, and radioactive contamination from the thermonuclear explosion is small. It is the smallness of radioactive contamination that makes the fusion reaction so attractive compared with the fission reaction, as the ultimate source of power for the world.

PROPULSION BY IONS AND IONIZED PLASMAS

By Dr. A. von ENGEL

Visiting Professor of Physics, University of Oklahoma, Norman, Oklahoma

RECENTLY a concerted effort has been made in the United States to look for new types of fuel for the propulsion of rockets and space vehicles of various kinds. From papers given at a conference at the University of Maryland in October 1958, held under the auspices of the U.S.A.F. Air Research and Development Command, and from other communications, it appears now feasible to use other than the usual sources of chemical energy (combustion). More powerful fuels include free radicals, ions and plasmas. More than a hundred research projects are directly or indirectly connected with a study of this problem. Most of the work is done in universities, industrial and research corporations in the United States, some in Great Britain and in Germany. The results can be applied to military purposes, to pure research and to transport of mail and goods. Besides inter-continental postal service, it is thought to be of interest for the supply of the future space platforms.

As to the unorthodox type of chemical fuels, free radicals and atoms or molecules in a higher state of electronic excitation and dissociated molecular gases are being explored. The difficulty to be overcome is to obtain sufficiently large concentrations and amounts of the substances, and to prevent a release of their potential energy by reaction with the walls of the container, or corrosion during storage. Though some progress has been made, for example, in reducing the rate of association of atoms by freezing them into a solid matrix[1], it is not possible yet to make practical use of dissociated gases for propulsion.

An important parameter in rocket design is the thrust, f, per unit terrestrial weight of fuel expended in unit time, W, called the specific impulse I_s (in sec.). Numerical considerations show that I_s is lowest in the case of propulsion by an effluent compressed gas. For a gas of molecular weight M escaping through a nozzle with the velocity v, we have $I_s = f/W = (RT/M)/(gv)$. For air at room temperature flowing with molecular velocity, I_s is less than or equal to 100 sec. The conventional chemical reactions give values of I_s larger by about a factor 4 or so.

To obtain a large thrust acting on vehicles travelling with constant speed, both the rate of fuel expended and the exhaust velocity must be large. Thus positive ions have been suggested as fuels, since it is relatively easy to accelerate them to a speed of $v_i = 10^6$ cm./sec. and more. Here $I_s = v_i/g$ and is of the order 10^3–10^4 sec. For thrusts of 10^9 dynes, dm/dt becomes 10^3 gm./sec., and with heavy ions this would correspond to emission currents of 10^6 amp., which is beyond practical limits even during short periods. However, for controlled space vehicles 100–1,000 amp. lasting several years would be sufficient. The corresponding small thrusts would be convenient in navigation[2] ('astronautical attitude control'). Currents of that order could conceivably be drawn from cæsium–tungsten, or cæsium–tantalum, where cæsium atoms diffuse through the porous metal kept at about 1,100° K. into a vacuum. The cæsium atoms are thereby ionized, because the work function of tungsten or tantalum is larger than the ionization potential of cæsium. Present experiments give currents much less than the values quoted above. The size of the pores must be chosen so as to prevent unnecessary evaporation of neutral cæsium atoms. Erosion of the cathode by the fast cæsium ions can be reduced by careful design of the geometry of the electrode. In order to avoid electrostatic drag, the ion exhaust charge is to be neutralized by feeding electrons into it. Other sources of ions use hydrogen ions emitted from a heated palladium foil through which hydrogen is passed, and alkali ions by electrolysis through glass membranes[2].

Another means of propelling vehicles is to apply a mechanical pulse to the body to be driven by passing a current pulse through it while a magnetic field perpendicular to the current is established by the same current or separately. This is the principle of the electromagnetic gun, one of the ever-recurring war-time inventions. The limitations are obvious: a 50-gm. bullet of ½ cm. diameter fired with an initial velocity of 10^4 cm./sec. would require a charge of 10^3 coulombs in a field of 10^4 gauss. However, though the chances of success are slim, an investigation has been made of an accelerator firing projectiles of several hundred grams at 10^6 cm./sec. The accelerator is 10 m. long and has a single-layer winding along which slides a closely-fitting metal projectile. By means of precision switching, one turn of the winding after the other is made to carry the current; the switching is so timed that the electromagnetic impulse travels with the same speed as the projectile[3].

Instead of the metal projectile, a highly ionized gas may be used to obtain higher velocities, and several solutions have been envisaged which should give specific impulses of I_s equal to or greater than 10^3 sec. One method is to generate an arc discharge plasma in the form of a closed ring co-axial with a helical delay line. The plasma is accelerated by the radial component of the magnetic field of the helix while the arc current is maintained by the electromotive force caused by the difference between the velocity of propagation of the current in the helix and that of the arc plasma[4]. Another arrangement uses a number of discontinuous arc discharges in a uniform stationary magnetic field, whereby the plasma flames are led through an exhaust tube into the space[5].

An experimental study has been reported[6] recently which is another version of the shock tube[7], where the plasma itself represents the accelerated mass. An electromagnetically controlled valve admits a small amount of gas to an evacuated system. The gas is first feebly and afterwards fully ionized by a rapidly varying magnetic field. The plasma of the ring discharge formed is at the same time compressed radially and the shock wave so produced enters a tube inserted in a solenoid which is loaded with capacitors. This delay line acts as a magnetic piston which drives the plasma through the tube. The linear momentum of the plasma has been measured both by a capacitor microphone and a ballistic pendulum. Plasma speeds of 5×10^6 cm./sec. equal to the speed of the magnetic piston have been recorded with deuterium, and impulses of 80 gm. cm./sec. observed for single pulses. About one-fifth of the impulse is due to the neutral gas admitted.

A large number of investigations deal with the production and application of electric plasmas.

Exploding metal wires at low gas pressure have been studied[8], and with ion densities of about 10^{16}/cm.^{3} and current densities of 10^4 amp./cm.^{2} plasma accelerations up to 10^{13} cm./sec.^{2} are found. Plasma jets in helium using continuous electric arcs produce electrode and wall erosion which prevent their use when higher impulses are needed. These difficulties can be circumvented by using high-frequency electrodeless discharges induced by discharging a capacitor through a coil. The shock wave which ensues can be guided along the centre of the tube by axially symmetrical magnetic fields[9].

The design of electrodes and nozzles for the injection of the hot ionized plasma jet has been studied extensively. Such heads seem to work theoretically at pressures of 2,000 lb./sq. in. and power densities at the throat of the nozzle[10] of 5,000 kW./cm.^{2}.

Another problem which seems to be important in connexion with the plasma jet is the electric breakdown in a turbulent moving gas with the associated gas pressure and density gradients. Studies using Kerr cells in the millimicrosecond range and photographic measurements with a high-speed rotating mirror camera are being carried out[11].

Theoretical work is also being done to test whether the concept of magnetic pressure can be applied to all magnetohydrodynamic problems[12].

Plasma studies for propulsion and other applications may benefit from the work with transient magnetic fields[13] in the range 10^5–10^6 gauss. Coils with force-free windings have been operated which can stand the mechanical force components resulting from a slight unbalance, and it appears that this new tool may have a profound effect on atomic and nuclear research.

Studies of charge neutralization in plasmas have been made which show that the high values of recombination coefficients for electrons and positive molecular helium ions reported earlier (10^{-7}–10^{-8} cm.^{3}/sec.) seem to be erroneous. The neutralization processes have to be interpreted by including the formation of excited particles[14].

Measurements of the velocity of high-current arc flames in the pressure-range 760–20 mm. mercury have been carried out using carbon electrodes. The interaction of the tail flame with the magnetic field is already apparent in moderate fields. Since it depends upon the field gradient rather than the field, it is concluded that the electric dipole distribution in the flame is the cause of the interaction forces[15].

At low gas temperature, electric direct current or high-frequency discharges at various pressures in air have been used to produce supersonic jet exhaustion into a chamber kept at low pressure[16]. Measurements of the ion concentration as a function of the input energy show that about half the energy is used to dissociate the gas. Shock-free streams were obtained and it is hoped to increase the speeds up to Mach number 5.

High-speed flows have been obtained in the low-pressure wind-tunnel by ionizing the gas with high frequency at the exit of the nozzle. This method of heating the plasma avoids obstruction of the flow and contamination of the gas. With 1 kW. high-frequency supply, about 130 watts have been transferred to the gas, which was heated from room temperature to 1,000° C., and Mach numbers up to 3·5 were obtained. It is thought that in nitrogen the electrons recombine with the positive ions to give excited atoms with the release of kinetic energy and that afterwards the excited nitrogen atoms combine with atoms in the ground-state again, releasing kinetic energy. Both stages are accompanied by emission of quanta[17].

The heat transfer from an ionized gas to the walls has been investigated experimentally with a plasma jet of about 2 cm. diameter at subsonic speeds. The walls act as a calorimeter, and an essentially axial magnetic field is produced by a variety of coils, so that the magnitude and structure of the fields can be varied[18] within wide limits up to 3×10^4 gauss.

The velocity of space vehicles is expected to be so large that considerable ionization will be produced in the rarefied gas through which they move. It has been suggested that the hot ionized gas may be guided through a magnetic field, and power drawn from the Hall current for ancillary equipment instead of using a conventional electric generator and other moving parts[19].

Other principles of propulsion have been suggested, such as fusion and light-pressure, and in both cases high specific impulses are theoretically expected. For example, for photons one finds $I_s = c/g$, which is of the order 10^7 sec.

CANADIAN CÆSIUM-BEAM STANDARD OF FREQUENCY

By S. N. KALRA, R. BAILEY and H. DAAMS
Division of Applied Physics, National Research Council, Ottawa, Canada

A CÆSIUM-BEAM frequency resonator has recently been completed in these laboratories[1]. It is similar in principle to the one reported earlier by Essen and Parry[2] but differs in methods employed for the synthesis and measurement of frequency, and in the detailed design of the atomic-beam apparatus. The potentialities of this technique have already been shown by the measurement of the frequency of the Essen–Parry resonator in terms of Universal Time 2 (ref. 3) and Ephemeris Time (ref. 4). The independent development of the resonator described here was undertaken in view of the importance of this technique in defining the frequency and a time interval. In this resonator, as in the one of Essen and Parry, the frequency of the transition $F=4, m_F=0 \longleftrightarrow F=3, m_F=0$ in cæsium-133 is measured by the use of the Ramsey technique[5] in an atomic-beam apparatus.

The transition region in this atomic-beam apparatus is 80 cm. long and the distance between the source and the detector is 210·5 cm. A beam height of 12·5 mm. and a beam width of 0·25 mm. at the source are used. The focusing magnets are each 20·3 cm. long with a pole gap of 7 mm. giving a field strength of 5,000 oersteds and a gradient of 5,000 oersteds per cm. The stray field from the focusing magnets is reduced almost to zero, by means of magnetic shields. The detector consists of a surface ionizer and an ion collector. A continuously pumped vacuum system is used and the operating pressure is usually less than 1×10^{-6} mm. of mercury. A cancellation of the Earth's magnetic field is obtained by means of two pairs of Helmholtz coils. One of these pairs also provides the operating C field. Fig. 1 shows a general view of the atomic beam apparatus.

The electromagnetic energy required for the resonance transition is obtained from a frequency synthesizer using vacuum pentodes, tetrodes and triodes with a final stage using a silicon diode as a frequency tripler. The driving signal for the synthesizer is obtained from a quartz-crystal oscillator

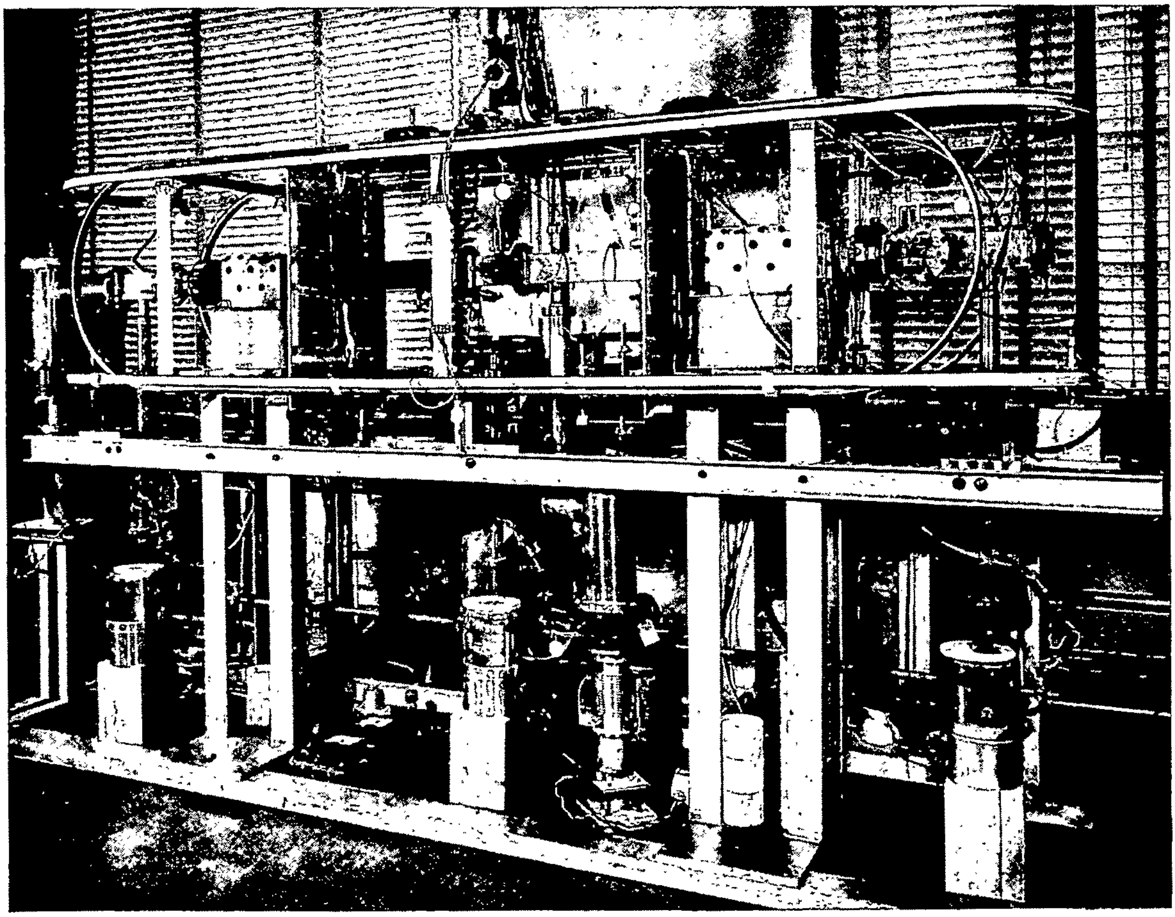

Fig. 1. Atomic-beam apparatus used in cæsium-133 frequency resonator standard

at 5 Mc./s. (nominal frequency) which can be varied continuously to sweep over the resonance line. A small portion of the energy being supplied to the atomic-beam apparatus is taken off by means of a directional coupler and fed to a balanced microwave mixer. This mixer is also fed with the 90,000th harmonic of one of the reference quartz-crystal oscillators[6] at 100 kc./s. The resulting beat note is at 192·6 Mc./s. A second beat is obtained between the first beat signal and the 2,000th harmonic of the reference oscillator, thus giving a signal at 7·4 Mc./s. This frequency is then measured by means of an electronic frequency counter. Fig. 2 shows a block diagram of the frequency-measuring chain described above. Great care has to be taken in keeping down the level of noise because of the high order of frequency multiplication involved. It is possible to make measurements of frequency to an accuracy of ± 1 c./s. or $\pm 1 : 10^{10}$ within 10 sec., which is nearly the limiting accuracy set by the quartz-crystal oscillators.

The source of cæsium atoms is an oven containing a mixture of cæsium chloride and sodium metal and heated to 200° C. The full width (at half intensity) of the resonance transition is measured to be 230 c./s., which is the expected value under the experimental conditions of the beam temperature and the length of the transition region. The frequency of the resonance transition is determined by measuring the frequency at points of equal amplitude on both sides of the resonance. A magnetic field or *C* field of 0·04–0·07 oersted is used such that a correction of the frequency of 1–2 c./s. is needed to obtain the frequency of the zero-field transition. This correction is determined and applied for each observation. The sensitivity of the measurements is about ± 1 c./s. or $1 : 10^{10}$ and the sum of the systematic errors is less than 10 ± 10 c./s.

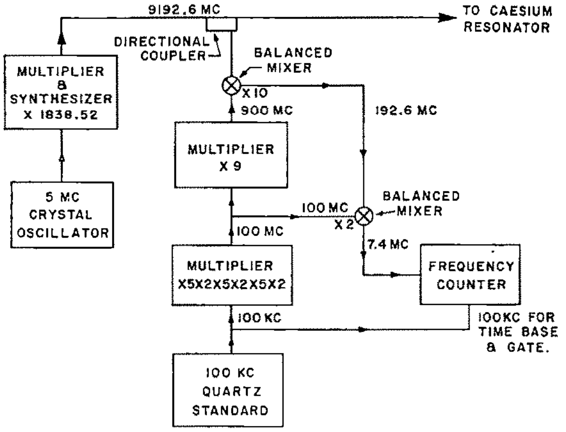

Fig. 2. Block diagram of the frequency-measuring chain used in cæsium-133 frequency resonator standard

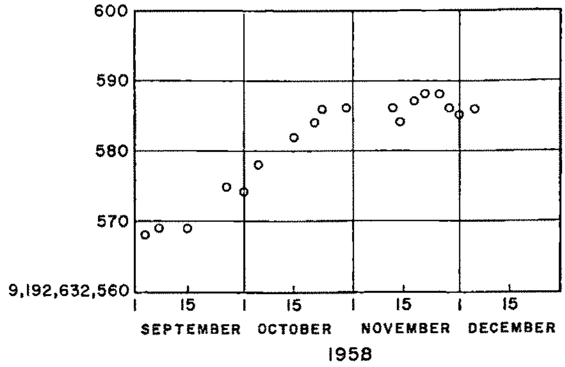

Fig. 3. Ratio of the frequency of the cæsium-133 resonance transition and reference oscillator *AP*. The ordinate expresses the ratio, or the frequency of cæsium-133 resonance under the assumption that the reference oscillator has the exact nominal frequency

The ratio of the frequencies of the cæsium-133 $(4,0 \longleftrightarrow 3,0)$ transition and the reference oscillator *AP* (100 kc./s. nominal frequency) is shown in Fig. 3 for a period of three months. It should be emphasized that the ordinate in Fig. 3 does not represent the frequency of the cæsium resonator in cycles per second, but is simply a ratio determined in the course of measurement of the frequency of one of the reference quartz-crystal oscillators against the cæsium resonator. The second of Universal Time 2 as tentatively determined for September 1958 by the Dominion Observatory, Ottawa, gives 9 192 631 935 ± 50 c./s. as the frequency for the cæsium transition $F = 4, m_F = 0 \longleftrightarrow F = 3, m_F = 0$ at zero field. This value is subject to revision as the unit of time is revised. The magnitude of the uncertainty is governed mainly by the accuracy of the determination of the second.

OBITUARIES

Mr. F. R. Petherbridge

Frederick Robert Petherbridge died on August 15, 1958, at the age of seventy after a long illness. Before his retirement in 1946 he was widely known and respected in agricultural circles for his work in applied entomology. When first appointed as advisory biologist, under the Ministry of Agriculture and Fisheries, he was expected to advise single-handed on pests and diseases of field and fruit crops throughout the Eastern Advisory Province and also to undertake seed testing. Later, after the appointment of Dr. W. A. R. Dillon Weston as mycologist, Petherbridge devoted his time entirely to pests. Together they were able to win the confidence of East Anglian farmers and to enhance the reputation of the School of Agriculture, Cambridge, both provincially and nationally as a source of advice on pests and diseases.

Robert Petherbridge was born, the son of a fruit dealer, on March 9, 1888, in Allerford, Somerset, and was educated at West Somerset County School and Sidney Sussex College, Cambridge. He obtained first-class honours in the Natural Science Tripos Part I in 1909, and took the diploma in agriculture in 1910. Though lacking inches he was a very good association football player, but it was his keen interest in rugby that most of us will remember, and especially his regular attendance at the Oxford–Cambridge match.

After a short period at Rothamsted Experimental Station, where he was contemporary with Sir John Russell and the late Tom Goodey, he returned to the University School of Agriculture, Cambridge, in 1912, as advisory biologist, continuing in that post until 1946. Being a member of the advisory staff, Petherbridge played only a minor part in formal teaching in the School of Agriculture, but his wide experience and his genial influence was exercised in the supervision of students and the training of research workers, many of whom now hold important posts. His approach to research was essentially practical, and many students fresh from academic training had cause to be very grateful to him for a thorough grounding in field-work.

A good deal of Petherbridge's early work was done on fruit in the Histon-Cottenham and Wisbech areas and later in Essex. He was able to identify at a glance all common varieties of fruit, and the advice he gave was always based on sound practical and economic considerations. But though fruit pests claimed much of his time he was also a pioneer in many other aspects of pest control, particularly those of arable Fenland crops. The onset of the Second World War and the vigorous policy of ploughing up grass led to the setting up of a wireworm team which, besides advising farmers, undertook research on factors affecting population-levels.

Petherbridge began an association with the Committee for Sugar Beet Research in 1934 and initiated work on sugar beet pests. In a determined effort to avoid the difficulties from beet eelworm which had plagued the Continental beet sugar industry, he proposed legislation to regulate frequency of cropping in the important Fenland area. This proposal was accepted and formed the basis of the Sugar Beet Eelworm Order, still in force. Another interesting proposal, which was not accepted, was the eradication of the spindle tree, the winter host of the black bean aphid and a scourge to beet seed and root crops.

Petherbridge's dynamic personality always claimed serious attention at the conference table and at meetings of applied biologists everywhere. He fought enthusiastically and successfully for raising the salary and the status of the adviser and particularly that of his assistants and of junior entomologists elsewhere in the service. He abhorred red tape and he was very disappointed when the old advisory service was dissolved and the National Agricultural Advisory Service was formed in 1946; all members of the team that he had gathered together left the Service at this juncture and he himself retired early. For some years he maintained his interests in association with Pest Control, Ltd., and continued to serve as consultant entomologist to the Royal Agricultural Society of England—a post he took over from the late Cecil Warburton.

F. G. W. Jones

Dr. F. A. Burchardt

Dr. F. A. Burchardt, who died on December 21 in Oxford at the early age of fifty-six, was acknowledged to be one of the most perceptive and vigorous economists of his time. His work at the Universities of Kiel and Frankfurt had, nearly thirty years ago, already established his reputation as a theoretician; but his intellectual and personal integrity was enough to ensure his dismissal as soon as the Nazis took power. For two tense years he worked as economic and financial editor of the *Frankfurter Zeitung*—until this last foothold became untenable. He arrived in Oxford in 1935 with a small research grant from All Souls College. He now had simultaneously to adapt himself to a new academic climate, to master the difficulties of teaching and lecturing in a strange language, and to build a fresh background for his young family.

Burchardt turned his mind to statistics and applied economics: indeed, he did much to establish empirical economic research in Oxford. He joined the staff of the Institute of Statistics, eventually becoming its director in 1949. He had been elected a Fellow of Magdalen College the year before, and in 1950 was appointed reader in economic and social statistics in the University. During 1952 he went to Stanford University as visiting professor; in the same year he became a governor of the National Institute for Economic and Social Research; in 1954 he was elected a member of the International Statistical Institute and a Faculty Fellow of Nuffield College; he reported for the European Productivity Agency in 1955, and worked in the Economic Commission for Europe during 1956–57. His help was welcomed in many other fields—among them that of adult education both in Britain and in Germany.

He had an immense capacity for work, and combined his many activities with devoted service to the Institute of Statistics, his College, and the University. An unfeigned interest in other people's views, a startlingly quick perception of what they were trying to say, and a faculty—almost an instinct—for distinguishing truth from mere plausibility made him an outstanding teacher. At the Institute, he inaugurated many pioneering projects in applied economics. Although he provided an unfailing stimulus to his colleagues, never grudging them detailed criticism, he never took credit and always encouraged them to claim, and to achieve, their independence. Those who knew him will always remember his intellectual vitality, his ready humour, and his utter unselfishness.

K. G. J. C. Knowles

The Hon. Mrs. Ursula Grant Duff

The Hon. Ursula Grant Duff, widow of Lieut.-Col. Adrian Grant Duff (killed in action in 1914), died on January 15, a few days before her seventy-fourth birthday, and was buried at High Elms, Farnborough, Kent. Her father was Sir John Lubbock (later Lord Avebury); her maternal grandfather was the pioneer archæologist, General Pitt-Rivers; and at High Elms, where Charles Darwin was a neighbour, she grew up in one of the liveliest centres of intellectual ferment in England.

Many sorrows followed the death of her father in 1913, but she continued the High Elms tradition at her Chelsea home with infectious gaiety and unassuming devotion to the improvement of personal, intergroup and international relations. The leading figures of the biological and social sciences were among her frequent guests, but there were always younger workers and representatives of other disciplines to meet them. Her relations with *Nature* and its contributors were particularly close.

Her own interests ranged from liberal rationalism and the rights of women to eugenics and constructive forestry; but all were linked in her mind as ways to the good life, and all arose from the scientific attitude in which she had been bred. Unfortunately, she could attempt no major synthesis, though she wrote and lectured on these questions with judgment, wit and uncompromising humanism.

She also did much to perpetuate her father's reputation, notably by her excellent symposium on "The Life and Work of Lord Avebury" (1924); and she has added to it the esteem in which she was widely held.

Cedric Dover

NEWS and VIEWS

Forestry at Oxford: Sir Harry Champion, C.I.E.

The retirement of Sir Harry Champion as professor of forestry at Oxford and the consequent appointment of Mr. M. V. Laurie serve to mark a notable period of development. Sir Harry succeeded in 1940, on the death of Prof. R. S. Troup, and at a time when changes in India, counterbalanced by the rising importance of forestry in the Colonies, necessitated re-organization and development: the increasing need for research was also being realized. It has been Sir Harry's main achievement to organize and carry through successfully the changes thus required. Outstanding points have been the change of forestry to an Honours School; the increasing development of postgraduate work; the occupation of the new building in 1950; and the necessary enlargement of staff and work. Sir Harry's wide experience and energy will be much missed and all hope that they will find further fruitful occupation.

Prof. M. V. Laurie

Sir Harry was central silviculturist at Dehra Dun, India, before going to Oxford, and Mr. M. V. Laurie followed him there in that post. Now he is again following him, this time at Oxford. Mr. Laurie was born in 1901 and trained at Cambridge. He retired from the Indian Service in 1946 and became chief research officer in the Forestry Commission. He comes thus with the experience in both tropical and temperate forestry which is desirable at Oxford. The prospects of the present time indicate that change and development will still be necessary in forestry, and he will receive all good wishes for his future work.

Organic Chemistry at Perth, Australia: Prof. D. E. White

Dr. D. E. White has been appointed to the recently established chair of organic chemistry in the University of Western Australia, Perth. Prof. White graduated from the University of Sydney in 1930 with first-class honours in organic chemistry, and later obtained the D.Phil. (Oxon.) for his work with Sir Robert Robinson during 1934–36. After experience with I.C.I. (General Chemicals), Ltd., at Widnes, Lancs, as tutor at St. Andrew's College, Sydney, and biochemist in the School of Public Health and Tropical Medicine in Sydney, he was appointed lecturer in organic chemistry in the University of Melbourne in 1940 and senior lecturer in charge of organic chemistry in the University of Western Australia in 1943. From the time of his arrival in Western Australia he has taken advantage of the existence of a unique natural flora, and has devoted his research interests to the organic chemistry of plant products.

White has been associated with the identification of 'callitrol' as citronellic acid, the elucidation of the structure of ravenelin, the synthesis of myristicin, a survey of Australian anthocyanins and the identification of genistein as the major œstrogen in subterranean clover. In recent years he has been working on the structures of sesquiterpene, diterpene and triterpene compounds isolated from Western Australian plants and has built up an active and well-equipped research school now numbering about twelve honours and Ph.D. students. In addition to his research activities, White has taken a keen interest in both undergraduate teaching and in extramural activities. He was president of the Royal Society of Western Australia during 1955–56 and is now president of the Western Australian Branch of the Royal Australian Chemical Institute and dean of the faculty of science at the University of Western Australia.

Andreas Sigismund Marggraf (1709–82)

'The second father or renewer of chemistry', Andreas Sigismund Marggraf was the son of Henning Christian Marggraf, chief apothecary to the royal court at Berlin, and was born 250 years ago on March 3, 1709. He studied chemistry, pharmacy, medicine, mineralogy and metallurgy at Berlin, Halle and Freiberg. In 1754 he became director of the chemical laboratory of the Berlin Academy of Science (later called Royal Prussian Academy of Science) and of its physics class in 1760. An able experimenter, a skilled analyst and a voluminous writer, he was responsible for a number of far-reaching contributions to chemistry, chemical industry and national economy. He made the microscope a useful aid in the chemical laboratory; worked out a cheap method for the preparation of phosphorus and of phosphoric acid, which laid the basis for important industries; prepared phosphorus pentoxide and showed that phosphorus is contained in urine as phosphates. He produced potassium cyanide, demonstrated its capacity of forming double salts with those of the heavy metals, and introduced the ferro-ferricyanides as reagents for iron. It was his preparatory work that led to the isolation by Sir Humphry Davy of the metallic elements potassium, sodium and magnesium. In 1768 Marggraf obtained hydrogen fluoride by the distillation of fluorspar with sulphuric acid. The value of his discovery of sugar in the sugar beet was only appreciated during the continental blockade of France in 1806. Marggraf died in Berlin on August 7, 1782. His collected writings were published under the title "Chymische Schriften" in two volumes (1761, 1767).

The Heaviside Manuscripts

The Institution of Electrical Engineers' "Heaviside Centenary Volume" (1950) contained a long article by Mr. H. J. Josephs, of the Post Office Research Station, describing the contents of various unpublished Heaviside manuscripts in the possession of the Institution; much of the material would have found a place in the projected but never completed Vol. 4

of Heaviside's "Electro-magnetic Theory". In 1957, in a house at Paignton, once occupied by Heaviside, a further collection of his manuscripts was discovered; these are now described by Mr. Josephs in the Institution's Monograph No. 319.

Some of these notes seem to be corrections and amplifications of Vol. 2 of the "Electro-magnetic Theory", which Heaviside would have incorporated in this volume had not the publishers insisted on a simple reprinting of the articles in *The Electrician* which formed the substance of the treatise. They show the emphasis placed by Heaviside on a symmetrical formulation of the electro-magnetic equations which, while not improperly called Maxwell's, seem to have been first stated explicitly by Heaviside; and they show his interest in, and attempts to establish, a unified field theory embracing both electromagnetic and gravitational phenomena, based on a general energy-flow equation. They also contain much about Heaviside's operational calculus, particularly in connexion with fractional differentiation, and suggest that Heaviside explored the idea of treating p not simply as the differentiation operator, but as the parameter in an integral transform, a point of view much closer to present-day interpretations of his calculus.

Whether or not a careful analysis of the large mass of papers found at Paignton would now be worth while, Mr. Joseph's article can only increase respect for Heaviside as an unorthodox but brilliant mathematician. Mr. Joseph revives the comment that Heaviside's operational methods made no appeal to mathematicians because such methods did not conform to the standards of rigour fashionable at the time; this is not in agreement with the conclusions reached by Prof. J. L. B. Cooper, who has discussed the point in considerable detail in an article in the *Mathematical Gazette* for February 1952.

Isaac Newton Telescope

FINANCIAL approval has been given to proceed with the construction of the proposed 98-in. Isaac Newton telescope which will be erected at the Royal Greenwich Observatory, Herstmonceux. This project was sponsored by the Royal Society, at the instance of the Royal Astronomical Society, and approved in principle by the Treasury and the Board of Admiralty in 1946. The design of the instrument received careful consideration by the scientists concerned, and development work was undertaken. In 1955 it was decided that the new Astronomer Royal should, on appointment, be given the opportunity of considering the final form of the telescope, and a quotation for construction of the instrument was obtained in November 1956. Owing to lack of funds, it was not then possible, however, to proceed with the actual construction. The new telescope, which will be the largest in the United Kingdom, will be used by visiting astronomers as well as by the staff at the Royal Observatory. The cost of the whole project, including erection and preparation of the site, is estimated at £660,000 at present prices, and will take five to six years to complete. Expenditure will be shared equally between the Treasury and the Admiralty.

The Isaac Newton telescope will be designed for use at the prime focus, Cassegrain focus, and coudé focus. Special attempts will be made to design a Cassegrain combination suitable for astrometry. The telescope tube will be held in an open fork with no north support; the Cassegrain focus will be reached from a platform carried by the telescope itself. It is intended to carry out an extensive programme of parallax work at the Cassegrain focus, using the large aperture to observe much fainter stars than are accessible to the comparatively small refractors now used on parallax work. The telescope is very flexible as regards choice of programme, and at present it is intended to concentrate the spectroscopic programmes on the precise determination of radial velocity, especially in those cases where individual stellar velocities may be supposed to be important in connexion with problems in stellar dynamics. In particular, it is planned to provide a large grating spectrograph at the coudé focus, with cameras of approximately 100-in., 60-in. and 30-in. focus. The prime focus will be available for the direct photography of stellar fields of interest in radio astronomy, and will be equipped with a field-correcting lens.

Effects of the Aurora on Radio Reception

A RESEARCH station to study the effects of the aurora on radio reception is to be set up on the site of a former radar station at Hillhead, near Fraserburgh, in Aberdeenshire. This investigation, part of a programme of ionospheric studies, will be undertaken by the Stanford Research Institute of America in collaboration with scientists from the Royal Radar Establishment of the Ministry of Supply. Observations will be made with a large parabolic reflector about 140 ft. in diameter brought from America. The experiments are expected to start in the late spring or early summer and will last one or two years. The cost will be borne by the Stanford Research Institute. The Aberdeenshire site has been chosen because of its geographical suitability for the study of auroral phenomena. There will be no radiation danger, and interference with radio and television will be prevented by the operating conditions laid down for the installation. There should be no restrictions on agricultural work, except that the vicinity of the installation must be protected from damage by livestock.

Biochemistry at the Royal College of Surgeons

IN days gone by, surgical shock was interpreted in terms of vaso-motor reactions and nervous responses to the stimulus of a severe injury. To-day attention is directed rather to the metabolic (chemical) response to injury, and since a chemical mechanism is now known to underlie the phenomena of shock, its treatment must be chemical also. Hitherto the process of wound healing has been regarded as a matter of cellular and vascular processes, explicable on a histological basis. But there was a mysterious initial phase when nothing could be seen to be going on in the wound, sometimes referred to as 'the lag period'. Recent research has shown that during these early days there is intense chemical activity in the wound, resulting in the accumulation of certain substances which are essential for the natural process of repair and without which the lag period may be indefinitely prolonged. There are profound biochemical changes in patients suffering from cancer, and furthermore there are tumours which are known to depend for their growth upon certain chemical substances, the deprivation of which can result in such diminution of growth as to suggest the possibility of treating cancer by chemical means. These are only examples to indicate the importance of biochemistry in surgery to-day, and it is no wonder that the Council of the Royal College of Surgeons decided some time ago to establish a sub-department of biochemistry in the Department of Physiology, with the dual purpose of promoting research and of amplifying the educational facilities which the College provides for postgraduates studying the basic medical sciences. The College has long looked forward to establishing a chair of biochemistry, and is deeply indebted to Mr. Jack Cotton for his recent gift of £100,000, which will make this possible.

Arrival of *Methane Pioneer*

Methane Pioneer, which left the Gulf of Mexico on January 31, arrived at Canvey Island, Essex, on February 20 with an experimental cargo consisting of 2,000 tons of liquid natural gas (methane) from one of the Gulf Coast oilfields. After liquefaction, which reduces it to 1/600th of the volume occupied in gaseous form, it was loaded into five special tanks in *Methane Pioneer*, which is owned jointly by the Gas Council of Great Britain and Constock International Methane, Ltd., of the United States. The tanks are of aluminium with a 12-in. insulation of balsa wood and an outer jacket of steel. The liquid will be pumped from *Methane Pioneer* and through an insulated pipeline from the jetty to two storage tanks, each with a capacity of about 1,000 tons of methane. One has been built for the North Thames Gas Board by the Whessoe Company, Ltd., of Darlington; the other by the A.P.V. Company, Ltd., of Crawley. Although these shore storage tanks are heavily insulated there will be a continuous boil-off of gaseous methane, and this material will be contained in a small gas-holder of the dry-sealed Wiggins type, whence it will be pumped into the mains system. Liquid methane will be vaporized by heat exchange with water or steam, and there is no intention at this stage of making use of the refrigerating capacity of the methane, which is at −260° F. The liquid will be converted to gas under pressure, and this pressure will be used to convey the gaseous methane into the transmission lines of the North-Thames Gas Board. A new transmission line has been laid from Canvey Island to connect with a high-pressure main already in existence between Shellhaven and Romford Works, and the gaseous methane will mix with refinery gases from the Shellhaven refinery. The town's gas supplied by the Board is distributed at 500 B.Th.U./ft.^{3}, while the methane has a calorific value of 1,000 B.Th.U./ft.^{3}, and reforming of the methane into gas of 500 B.Th.U./ft.^{3} will be carried out at Romford by the Onia-Gegi catalytic process. The gas after reforming will have similar characteristics to gas normally produced from coal and will be suitable in every way for consumers' appliances, with the added advantage that it will be free from sulphur. If these trials prove successful, both technically and economically, consideration will be given to the import of liquid methane on a much larger scale. Vessels carrying some 30,000 tons will probably be required in order to secure real economy.

Noise in Industry

In a written reply to a question about studies of the incidence and effects of noise in industrial establishments, Mr. H. Nicholls, as representing the Lord President of the Council, said in the House of Commons on February 13 that the National Physical Laboratory undertook surveys of noise for industry and advised on appropriate treatments to reduce noise inside and outside offices, factories, etc., caused by machinery and equipment used in the factory. The Laboratory also made fundamental investigations on the 'subjective loudness' of different types of noise. The Building Research Station was conducting surveys related to factory design, construction and use, and the effect of factory noise on neighbouring areas. Several grant-aided research associations were also actively interested in noise abatement although their research was mostly at an early stage. These studies were in addition to those of the Medical Research Council attempting to define the normal deterioration that occurs with age and the extent to which this may be modified by exposure to industrial noise. Papers had been and would continue to be published by the Stationery Office and in the technical press.

A Register of Historic Aircraft

A first practical step towards a national aeronautical museum was taken at a meeting held at the Royal Aeronautical Society at the end of January under the chairmanship of Mr. Peter G. Masefield, president-elect of the Society. At this meeting, which was attended by twenty-six representatives of Government departments and other public bodies, it was agreed to compile a register of aircraft of major historical importance in Great Britain with the view of their preservation. The need for a national British aeronautical museum has been felt for a long time by many in the aircraft industry who are anxious that historic aircraft should be preserved. Since the Royal Aeronautical Society acquired the aircraft of the Nash Collection of Early Mechanical Transport in 1953, so that these historic aircraft should remain in Britain, the Society has hoped that they would eventually form part of a national aeronautical museum. The decision to compile a Central National Register means that the whereabouts and condition of all historic aircraft still in Britain will be known and plans to ensure that they are not destroyed can be put in hand. The number of these valuable and irreplaceable aircraft is steadily dwindling because of a lack of national policy. A sub-committee under the chairmanship of Air Commodore A. H. Wheeler, trustee of the Shuttleworth Collection, has been formed to supervise the preparation of the Register. The Royal Aeronatical Society has already been greatly helped by many enthusiasts, but it is clear that there must be many relics still in private hands, and the Society appeals to all who possess old aeroplanes or aero-engines or who know where they are to inform the Society of their location and condition so that, if possible, they may be added to the Register. Information should be sent to Mr. A. S. C. Lumsden, Royal Aeronautical Society, 4 Hamilton Place, London, W.1.

Institution of the Rubber Industry in South Africa

The first steps are being taken to establish a South African Section of the Institution of the Rubber Industry, consisting of a central Council in Johannesburg with branches in Johannesburg, Durban and Port Elizabeth. The aims of the new Section will be to promote the development of polymer science and technology, to encourage technical education and provide a means of association between persons engaged in the rubber industry in South Africa. South African companies and personnel engaged in rubber and plastics manufacture are invited to apply for membership of the Section. The addresses of the honorary secretaries are as follows: *Johannesburg*,

F. C. Moore, Durham Raw Materials, P.O. Box 4142, Johannesburg; *Durban*, A. J. Robertson, P.O. Box 1515, Durban, Natal; *Port Elizabeth*, W. Pickup, P.O. Box 3062, North End, Port Elizabeth.

The Translations Bulletin

THE *Translations Bulletin* of the Lending Library Unit of the Department of Scientific and Industrial Research, the first issue of which appeared in January, replaces the *Translated Contents Lists of Russian Periodicals* previously issued by the Unit. In so far as it also includes articles on scientific or technical developments in the U.S.S.R., the claim that it is a new publication is justified and there are also lists of translated Russian books in print or printing; translated or being translated; and suggested for publication. It represents also a considerable modification of the arrangements for co-operative Russian translations. In the new *Bulletin* lists are given of cover-to-cover translations of Russian periodicals and of translations of Russian articles available from the Library Lending Unit. In future, however, instead of referring to the *Translated Contents Lists of Russian Periodicals* previously issued by the Department at the same price as the new *Bulletin*, it will be necessary to subscribe to the *Monthly Index of Russian Accessions*, available from H.M.S.O. (U.S.A. Section), P.O. Box 569, London, S.E.1, the subscription to which is about £5 7*s*. 6*d*. a year. This has the advantage of being more comprehensive than the *Monthly Index*, but apart from being a little later, its greater bulk may be a disadvantage in the circulation to departmental specialists on whom a university librarian, for example, will doubtless rely for requests for translations. The decision whether a translation shall be made, however, rests with the Department itself instead of with the potential user. Under the previous scheme a translation would be made at the request of two or more users, the cost depending on the number of requests received. This may, however, become less important as the co-operative scheme with the National Science Foundation for cover-to-cover translation of periodicals develops, under which twenty-four periodicals are already listed for translation in the January issue of the *Bulletin*.

Overseas Geology and Mineral Resources

THE quarterly bulletin of the Overseas Geological Surveys, formerly known as *Colonial Geology and Mineral Resources*, and published by H.M. Stationery Office, London, has been renamed *Overseas Geology and Mineral Resources* as from Vol. 7 (1), 1958, in order to be more in keeping with the changing status of the territories for which it caters. The bulletin will continue to cover topics concerning all the territories, whether dependent or independent, that previously came within its purview.

Australian Defence Standards Laboratories

THE 1956 report of these Laboratories has recently been released. It contains an interesting account of a surprisingly wide range of activities. The scope of the investigations is indicated by the inclusion of studies of such diverse subjects as detergents, radio spectroscopy, paint, textiles, rubber, radiological physics and viscometry. Worthy of special mention are three items of considerable interest. First, xerography has been explored with particular reference to the employment of liquid developers of high volume-resistivity such as carbon tetrachloride. By using such liquids a considerable improvement in resolution has been achieved. This has important applications for radiographic purposes and in continuous-tone photography. Second, a new method for graticule production—the interstitial process—has been developed. This has already been described in *Nature* (January 24, p. 223), where the Laboratories were incorrectly named 'Reference' instead of 'Defence Standards Laboratories'. Third, work on a multi-cell-unit dry battery has produced promising results. After manufacture, the battery is dehydrated under heat and vacuum. It is then in a suitable condition for storage. When required for use, the battery is activated by the addition of water.

Lady Tata Memorial Trust Scholarships and Fellowships

THE Trustees of the Lady Tata Memorial Trust invite applications for grants, scholarships or fellowships for research on diseases of the blood, with special reference to leukæmia, in the academic year beginning on October 1, 1959. In view of the affinity between leukæmia and other forms of neoplastic disease, candidates with programmes of research on any aspect of malignant disease which may throw light on problems of leukæmia will also be eligible. Grants of variable amount are made for research expenses or to provide scientific or technical assistance for senior workers. Scholarships are awarded for the personal remuneration of workers carrying out approved research under suitable direction; their normal value will be £600 per annum. In addition, the Trustees may award one or more Lady Tata Memorial Research Fellowships to workers with considerable research experience; the stipends of these Fellowships will be at the rate of £1,200 per annum. Further particulars and forms of application can be obtained from the Secretary of the (European) Scientific Advisory Committee, Lady Tata Memorial Trust, Chester Beatty Research Institute, Fulham Road, London, S.W.3. Applications must be submitted before March 31.

University News: Bristol

MISS MARGARET RANDALL has been appointed organic chemist at the Long Ashton Research Station.

The University has received the following gifts and grants, among others: £8,341 from the British Empire Cancer Campaign for cancer research to be carried out in the Departments of Pathology, Physiology and Surgery; £2,500 from the Department of Scientific and Industrial Research, as a renewal of grant for Prof. C. F. Powell's work in the Department of Physics; £1,492 from the Agricultural Research Council to the Department of Veterinary Medicine for research on experimental transmission of lymphoid leukosis; £1,172 from the Agricultural Research Council to the Department of Physiology for research on bovine acetonæmia.

Liverpool

THE following appointments were recently made: P. E. Doak, to be lecturer in applied mathematics; S. L. Dixon, to be lecturer in mechanical engineering; D. Allan, to be lecturer in applied veterinary pathology.

The Night Sky in March

NEW moon occurs on Mar. 9d. 10h. 51m. U.T. and full moon on Mar. 24d. 20h. 02m. The following conjunctions with the Moon take place: Mar. 1d.

10h., Jupiter 3° S.; Mar. 3d. 22h., Saturn 4° S.; Mar. 12d. 00h., Venus 0·1° N.; Mar. 16d. 19h., Mars 7° N.; Mar. 28d. 18h., Jupiter 3° S.; Mar. 31d. 06h., Saturn 4° S. In addition to these conjunctions with the Moon, Mars is in conjunction with Aldebaran on Mar. 4d. 14h., Mars being 7·5° N. There is a partial eclipse of the Moon on March 24, visible at Greenwich. This is one of the final eclipses of a series which began in 985 and which will end in 2013. Mercury is favourably situated for observation during the first three weeks of the month. It is an evening star, visible for a short time after sunset. It sets at 19h. 45m. on March 15. Venus is an evening star, visible in the south-west after sunset. Conditions are steadily becoming more favourable for observation. Venus sets at 19h. 55m., 20h. 40m. and 21h. 35m. on March 1, 15 and 31, respectively; its stellar magnitude is $-3 \cdot 4$. Its distance decreases during the month from 137 to 122 million miles and the visible portion of the apparent disk decreases from 0·900 to 0·828. Mars is moving eastwards among the stars and is in Taurus throughout March. It sets at 2h. 05m., 1h. 50m. and 1h. 25m. at the beginning, middle and end of the month, respectively. Its stellar magnitude decreases from $+0 \cdot 8$ to $+1 \cdot 3$, its distance from the Earth increasing from 119 to 148 million miles. Mars is easily observed during the evening, but conditions are becoming less favourable. Jupiter rises at 1h. 10m., 0h. 20m. and 23h. 10m. on March 1, 15 and 31, respectively; it is near β Scorpii. The stellar magnitude of Jupiter is $-1 \cdot 8$; conditions for observation are not very favourable. The distance of Jupiter is approximately 460 million miles. Saturn is a morning star in Sagittarius, rising at 3h. 55m., 3h. 00m. and 2h. 00m. at the beginning, middle and end of the month, respectively. Its stellar magnitude is $+0 \cdot 8$ and its distance approximately 960 million miles. Conditions for observation are not favourable. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: Mar. 13d. 19h. 03·8m., 31 Ari. (*D*); Mar. 21d. 0h. 19·2m., A^1 Cnc. (*D*); Mar. 21d. 2h. 13·4m., A^2 Cnc. (*D*); Mar. 21d. 21h. 00·4m., 6 Leo. (*D*); Mar. 29d. 3h. 47·7m., χ Oph. (*R*). *D* and *R* denote disappearance and reappearance, respectively. The vernal equinox occurs on March 21d. 09h.

Announcements

DR. NYMAN LEVIN, deputy director of the Weapons Group of the United Kingdom Atomic Energy Authority since July 1958 (see *Nature*, **182**, 155; 1958), has been appointed director of the Group in succession to Sir William Penney. Sir William will succeed Sir John Cockcroft as the Authority's member for research when Sir John takes up his mastership of Churchill College. Dr. Levin is succeeded as deputy director of the Weapons Group by Mr. E. F. Newley.

MR. J. S. FULTON, principal of the University College of Swansea, has been appointed vice-chancellor of the University College of Sussex which is to be built on the outskirts of Brighton.

MR. ERIC K. COLE has been elected an honorary member of the British Institution of Radio Engineers in recognition of his services to the radio and electronics industry and profession. Mr. Cole is chairman and managing director of the firm bearing his name, which he founded in 1926.

VIRGIL H. DISNEY, director of electrical engineering research at Armour Research Foundation, has been elected president of the National Electronics Conference for 1959, the next meeting of which is to be held at the Hotel Sherman in Chicago during October 12–14. Further information can be obtained from the U.S. National Electronics Conference, 84 East Randolph Street, Chicago 1, Illinois.

DISCUSSIONS on expanding Anglo-Soviet educational, cultural, scientific and other exchanges during 1959–60 will begin in Moscow on March 24 between the Soviet Relations Committee of the British Council and the Soviet State Committee for Cultural Relations with Foreign Countries. The talks are expected to last about a week. The Soviet Relations Committee of the British Council was set up with Government support in 1955; it provides a representative organization to encourage, sponsor and organize Anglo-Soviet exchanges in various fields.

THE Clough Memorial Research Fund of the Edinburgh Geological Society is available for geological research in Scotland and the north of England (Northumberland, Durham, Cumberland, Westmorland and Yorkshire). Grants for the period April 1, 1959–March 31, 1960, will be made shortly, and applications, stating the nature of the proposed research, should be sent before March 31 to the Secretary, Clough Memorial Research Fund Committee, Edinburgh Geological Society, Synod Hall, Castle Terrace, Edinburgh 1.

BY arrangement with the Polish State Publishing House for Scientific Literature, Warsaw, an exhibition of Polish scientific books is being held by the Oxford University Press in Oxford at 116 High Street during February 21–March 7. A similar exhibition is being held in Cambridge at Messrs. Heffer during March 4–14, and in Glasgow at Messrs. John Smith during March 2–14. Oxford University Press books will in turn be exhibited in a number of Polish cities, including Warsaw, Cracow, Poznan, Lodz and Wroclaw. Subjects covered by the exhibition are anthropology, archæology, bibliography, biology, chemistry, economics, geography, history, law, linguistics, mathematics, philology, philosophy and physics.

THE Scottish Group of the Nutrition Society is to hold a symposium on Obesity, on April 4 in Glasgow. Those interested who are not already members of the Society may write for further particulars to Dr. J. Davidson, The Rowett Research Institute, Bucksburn, Aberdeenshire.

THE British Agricultural History Society and the Economic History Society are to hold a joint conference on Agriculture and Rural Life at Wye College, during April 10–13. Further details can be obtained from Mr. J. D. Sykes, Department of Agricultural Economics, Wye College, Nr. Ashford, Kent.

AN international symposium on experimental biology is to be held in commemoration of Lazzaro Spallanzani (1729–99) at his birthplace, Reggio Emilia, during May 2–9. Further information can be obtained from Prof. Carlo Jucci, Istitute 'L. Spallanzani', Palazzo Botta, Pavia.

IN his review of "Bibliography of Food", by E. A. Baker and D. J. Foskett, published in *Nature* of February 7, p. 351, Dr. Magnus Pyke states that "the authors do list Plimmer's historical tables of food composition and omit to mention the workaday ones of McCance and Widdowson". The latter tables are in fact listed on p. 285 and are indexed in both author and subject indexes.

RELAXATION PROCESSES

An informal discussion on "Relaxation Processes" was held under the auspices of the Faraday Society in the Department of Chemical Engineering, at the Imperial College of Science and Technology, London, on November 27. About eighty people from universities and industrial research centres both in Great Britain and abroad were present.

The chairman, Prof. A. R. Ubbelohde, welcomed the visitors and stressed the modern importance of relaxation techniques in the study of a wide variety of rate processes of interest to the physical chemist. The use of methods involving cyclic stresses could provide a valuable means of studying rate processes in systems only slightly perturbed from their equilibrium states, and made possible the correlation of rates with thermodynamic functions. This was of particular interest in the cases where the relaxation times could be associated with specific molecular mechanisms.

Prof. C. J. F. Böttcher (University of Leyden) presented a paper on the phenomenological study of dielectric relaxation. He considered a dielectric with polarization (strain) in the same direction as the applied field (stress), for the case in which there is a lag between stress and strain. If the stress is prescribed to rise and fall as a simple step-function with time, then the strain shows a simple retardation effect. If, on the other hand, the strain is prescribed to have a step form, then the stress required to effect this shows a relaxation effect. Since in practical dielectric measurements we work with a prescribed stress, it would seem logical to refer to the measured time-constant as the retardation time. He outlined the equations describing the variation of dielectric constant and of the loss factor with frequency. Although the retardation and relaxation times are not in general the same, they may be shown to have a simple mathematical connexion in this case and each can be related to a molecular relaxation time, so that the distinction between retardation and relaxation is in the nature of a formal rather than a physico-chemical one. The dependence on temperature of the molecular relaxation time can be understood by considering the relaxation mechanism as an Eyring type rate-process. Identification of the molecular process responsible for the macroscopic relaxation is facilitated by the experimental fact that a single relaxation curve is often obtained.

Illustrating the comparatively simple behaviour which could occur in complex molecules, Prof. Böttcher reported measurements on bromobenzene and cyclohexanol, each of which showed a single relaxation curve and mixtures of which showed only two relaxation times shifted towards each other, rather than a complex distribution of relaxation times.

Dr. Vera Daniel (Electrical Research Association, Leatherhead) described the results of measurements on a group of long-chain alcohols where anomalous dielectric constants (higher than those expected from the number of hydroxyl groups) are connected with the existence of polymeric forms of hydrogen bonds, so that the energy differences between the two forms of different polarization are small. Co-existence of these different forms is unlikely in a perfect crystal but likely at structural imperfections. Measurements were described on a variety of crystals grown from the melt or solution, containing different proportions of structural defects. These measurements, together with those of other investigators, indicate that chains of hydrogen bonds become polarizable in relation to some kind of flaw. For a maximum dielectric constant fairly long chains are necessary, combined with a sufficiency of flaws. The flaws occupy space and a texture was suggested in the materials which would give suitable flaws to explain the dielectric properties and a number of other properties of the crystals.

Mr. W. Reddish (Imperial Chemical Industries, Plastics Division), in a paper on solid polymers, indicated that the way in which polymers soften as temperature increases is dependent on time and hence possess relaxation characteristics. Results of detailed measurements of harmonic dynamic mechanical moduli and losses show strong correlation with measurements of dielectric relaxation obtained at the same frequency, in the case of several important polar polymers. Measurements of the mechanical moduli over a wide range of temperature together with dielectric measurements over a wide range of frequency show that cases of softening by a single process are rare; often two or more processes are observed widely separated on the temperature scale, a polycarbonate for example showing processes 250° C. apart. The number of processes possible seems to be related to the number of separate modes of rotational motion which can occur in the molecule, relatively free rotation of small groups occurring at low temperatures. These rotational motions may be inhibited in crystalline regions.

After comparison of dielectric and mechanical data for a range of compounds (especially when side-chains are varied systematically), it has sometimes been possible to suggest that particular relaxation processes are associated with motions of particular molecular groupings. Detailed models were discussed for polymethyl methacrylate and polymethyl chloracrylate. Another phenomenon of interest was that certain modes of motion observable mechanically but not electrically for non-polar polymers can be excited by adventitious dipolar impurities; for example, this function is attributed to carbonyl groups in polyethylene. Dielectric data for three processes for linear and branched slightly oxidized polyethylene were represented by means of solid models shown at the meeting.

In general discussion, Dr. C. W. Bunn (Imperial Chemical Industries, Plastics Division) raised a number of points connected with the hydrogen-bonded structures suggested by Dr. Daniel. Dr. R. B. Beevers (Courtaulds, Maidenhead) pointed out that the high values of the dielectric constant obtained by Dr. Daniel for specimens prepared from the melt may possibly arise as a consequence of the formation of a meso-phase in the melting region and suggested that it would be worth while to determine if such a meso-phase existed.

Prof. G. Gee (University of Manchester) criticized methods of analysing the dependence of relaxation times on temperature by means of the equation:

$$\log \tau = \log \tau_0 + E/RT$$

He pointed out, however, that a more precise analysis still gave remarkably large activation energies associated with the relaxation process in high polymers and suggested that this was because these were concerned with disturbances over large molecular areas of the material and not only with one bond.

Questions by Prof. Ubbelohde, Dr. Mansel Davies (University College, Aberystwyth) and Mr. B. Warburton (Distillers Co.) on matters arising from his paper were answered by Mr. Reddish. Dr. Greaverson (Shell) presented measurements on mechanical relaxation in polyethylene, Dr. G. Allen (University of Manchester) measurements on mechanical relaxation on rubber, and Dr. C. Brot (Paris) reported dielectric studies on liquid mono-alcohols of medium chain-length which showed three dispersion regions; these he interpreted in terms of molecular mechanisms.

In the second part of the meeting, Dr. J. H. Andrea (Imperial Chemical Industries, Research Department) presented results of ultrasonic relaxation measurements in liquids, ranging from low frequencies (100 kc./s.) where chemical equilibria involving rotational isomers may be perturbed by the sound wave and ultrasonic absorption observed, to the high frequencies (100 Mc./s.) where association–dissociation equilibria or slow redistribution of energy between translation and vibration may give rise to measurable ultrasonic absorption.

Dr. Andrea outlined ultrasonic measurements made by Dr. Lamb and his collaborators (Imperial College of Science and Technology, London) which gave values for the heats and entropies of activation in the passing from one rotational isomeric form to another, with particular reference to the substituted cyclohexanes. This gave a new method of measuring potential barriers hindering internal molecular rotation. He described the existence of an anomalous absorption region in toluene the origin of which is as yet unexplained.

Mr. J. Barlow (Imperial College of Science and Technology, London) described research in conjunction with Dr. Lamb, in which ultrasonic techniques were being used to determine the shear mechanical impedance of lubricating oils, as part of an investigation into the influence of the relaxation behaviour of molecules on lubrication. Measurements had been made for frequencies of the cyclic shearing stress in the region 10^4–10^8 c./s.: the effective range could be extended by variation of the temperature and pressure of the oil under test. All the experimental results for a given oil could be reduced to a single curve for each component of the complex shear modulus. This information was then analysed in terms of a spectrum of relaxation times. Qualitative correlation could be made between the relaxation spectrum and the proportions of the various hydrocarbon types in the oil.

Dr. J. C. McCoubrey (Imperial College of Science and Technology, London) gave a résumé of work on ultrasonic relaxations in gases which could be used to give quantitative transition probabilities for the process in which a molecular vibration was de-excited from the first vibrational level to the ground-state by a collisional mechanism. Some theoretical explanation of these transition probabilities in terms of molecular parameters could be given, but this was inadequate to explain the dependence of ultrasonic relaxation times on temperature. A new technique involving the use of interferometry to study the changes in density across a shock front in gases in which ultrasonic relaxation had been observed could yield measurements of the translation–vibration transition probabilities at temperatures up to 3,000° K., providing valuable tests for theories over a wide temperature-range.

In the general discussion, possible explanations of ultrasonic relaxation observed in toluene were suggested by Dr. J. A. Pople (National Physical Laboratory), Prof. H. C. Longuet-Higgins (Cambridge) and Dr. N. Sheppard (Cambridge). Some recent measurements on ultrasonics in gases were discussed by Mr. J. D. Lambert (Oxford), Dr. A. MacColl (University College, London) and Mr. T. L. Cottrell (Imperial Chemical Industries, Ltd.).

Finally, two new techniques giving information about relaxation times in energy transfer in gases were discussed. Dr. R. W. B. Stephens (Imperial College of Science and Technology, London) described an apparatus in which interrupted infra-red radiation is absorbed by a gas, and the vibrational energy taken up reappears as translational energy in the form of a pressure rise out of phase with the radiation input. The lag in phase depends on the relaxation time and this has been used to study relaxations in carbon monoxide and carbon dioxide.

Dr. A. G. Gaydon (Imperial College of Science and Technology, London) described an adaptation of the sodium-line reversal technique to the measurement of temperature changes in shock waves in gases showing relaxation. This procedure is probably capable of giving relaxation times at high temperatures more accurately than the interferometric study of density changes.

J. C. McCOUBREY

PLANT MORPHOGENESIS

A SYMPOSIUM on "Experimental Approaches to the Problems of Growth and Form in Plants", arranged by the Experimental Morphology Group of the Linnean Society, was held under the auspices of the Society in London during December 19–20. The symposium attracted a large and representative audience and was, in fact, an unusually interesting and successful occasion. It is probably true to say that this was one of the most varied and comprehensive treatments of plant morphogenesis that has been witnessed in Great Britain in recent years. (So considerable was the audience that the meetings had to be transferred to the rooms of the Geological Society.)

The papers presented at the symposium, some twenty in all, covered a wide range and explored the many aspects of morphogenesis by diverse experimental techniques. This wide spread of interest brought its own difficulties—the usual one on such occasions—that there was, unfortunately, all too little time for discussions.

It had been arranged that some of the longer contributions should be in the nature of general surveys. The opening paper, by Prof. C. W. Wardlaw, was of this kind, and dealt with observational, experimental and analytical methods which have contributed to our understanding of plant morphogenesis; Prof. L. J. Audus discussed both in general terms and with citation of specific examples the mechanism of correlation in plant development; Prof. J. Heslop Harrison similarly dealt in broad outline and in some detail with certain concepts of the action of growth substances in flower morphogenesis; and Dr. P. W. Brian gave an interesting account of morphogenetic situations in which the gibberellic acids were more or less directly involved. Also in the category of more general surveys, Dr. L. C. Luckwell outlined the very considerable scope for work on the factors controlling the growth and forms of fruits, and outlined some of the contemporary studies and achievements.

Among the many investigations of growth and form presented to the meeting, it was interesting to note that the algae (Dr. E. M. Burrows), fungi (Dr. N. Robertson) and mosses (Dr. J. H. Tallis; Dr. E. Lodge) had attracted their share of attention, as, indeed, they well might. Perhaps the most evident omissions were papers dealing with the contributions of tissue- and organ-culture techniques to morphogenesis; little was said about the action of physical factors in morphogenesis and, with some exceptions, genetical factors tended, on the whole, to be taken for granted and treated, as it were, in passing.

Considerations of space do not admit of detailed reference being made to the many papers contributed to the symposium. A high standard of interest was certainly maintained throughout. In the circumstances, the scope and vitality of contemporary work on the many aspects of morphogenesis in British universities and horticultural institutes may perhaps be indicated by citing the titles to which reference has not already been made: effects of environment on leaf development in *Impatiens parviflora* (Dr. A. P. Hughes); some factors affecting the production of stolons in the potato (Dr. A. Booth); the study of apical development in relation to etiolation (Dr. G. R. Lane and Mr. R. D. Butler); the experimental investigation of the pteridophyte life-cycle (Mr. P. R. Bell); changes in leaf arrangement in individual fern apices (Dr. E. G. Cutter); some growth responses to gibberellic acid (Dr. M. Y. Stant); the effect of very long days on the flowering of winter rye (Prof. F. G. Gregory and Dr. Olive N. Purvis); some effects of environment and hormone treatment on reproductive morphology in *Chrysanthemum* (Dr. W. W. Schwabe); floral morphogenesis in *Primula bulleyana* (Dr. F. Cusick); problems of juvenility and flowering in trees (Prof. P. F. Wareing); temperature-induced meristic and other variation in *Cannabis* (Dr. Y. Heslop Harrison and Miss I. Woods).

A complete number of the Linnean Society's *Journal of Botany* is being devoted to publishing the contributions to the symposium, and the papers are already in the hands of the printers. As it is anticipated that there will be a larger demand than usual for this number of the *Journal*, all those who are not Fellows or Associates of the Society, and who wish to have copies, should write for particulars, as soon as possible, to the General Secretary of the Linnean Society, Burlington House, Piccadilly, London, W.1. Early publication will not only make available a fund of valuable contemporary information but is also likely to provide a useful stimulus to further effort in this fascinating and central field of botanical science.

The officers of the Linnean Society are to be thanked for rendering a signal service by sponsoring the meeting. Thanks are also due to Prof. Heslop Harrison and Mr. P. R. Bell, who were responsible for the inception and arrangement of the symposium, and they are to be congratulated on the success of its meetings. C. W. WARDLAW

SCIENTIFIC COUNCIL FOR AFRICA SOUTH OF THE SAHARA

THE report* of the Secretary-General to the ninth meeting of the Scientific Council for Africa South of the Sahara, held at Accra during August 7–16, which surveys the activities of the Council during the year, is supported by lists of forthcoming meetings and of publications in 1958, and by particulars of the conclusions and recommendations of the Conference. Among the general conclusions of the Conference may be noted the Council's view that the Foundation for Mutual Assistance in Africa South of the Sahara will become one of the most active elements of the Commission for Technical Co-operation in Africa, and the emphasis placed on the very careful examination of each request for technical assistance in Africa in order to determine the best way of meeting it effectively. The Foundation now incorporates the earlier organization for the exchange of scientists and technicians.

Concern is again expressed at the accelerated rhythm of useless destruction and inconsiderate exploitation of Nature and natural resources, and the attention of Governments is directed to the need for agreement at inter-African level in the protection of this common economic and scientific inheritance. Such protection must be based essentially on a policy of rational utilization, and the Council recommended the urgent establishment of a committee for the conservation of Nature and natural resources in all African territories where no such organization exists; the appointment of an inter-African scientific correspondent responsible for ensuring liaison between the various territorial committees, to follow the evolution of common problems, and to keep the Commission and the Council informed; and the preparation of a charter for the protection of natural resources applicable to all territories in the African continent. The protection visualized by the Council comprises the management and supervision of areas which are properly exploited so that the amount of products consumed is commensurate with real social and economic needs and the possible renewal of resources; the establishment of adequate protective areas as indispensable reserves of flora and fauna; and the establishment of national parks and special reserves to protect certain resources of particular interest or value, which would otherwise become extinct or be rapidly exhausted.

Some change in the functions and activities of the Inter-African Bureau of Soils is recommended to the Third Inter-African Soils Conference to meet in the autumn of 1959, and the establishment of a panel of correspondents is recommended, as a matter of urgency, to cover physical oceanography, marine biology, the technology of fishing and the treatment of sea products. An inter-African scientific correspondent for oceanography and sea fisheries should be appointed to activate this Panel. Subject to confirmation by the Commission, the Council decided to call a meeting of specialists in 1959 to study research and related work in Africa on viruses and rickettsiæ common to man and animals, with particular reference to modes of transmission, host species and reservoirs and methods of control. The Council also recommended that the Commission should give closer consideration to the economic aspects of the technical problems with which it is dealing and that the Commission should undertake comparative studies of limited subjects of economic and financial interest, for example, the effect of demographic changes on economic development, and comparative studies of methods applied to encourage private investment and of methods for the stabilization of prices of agricultural products.

* Scientific Council for Africa South of the Sahara. Publication No. 32: Ninth Meeting of the Scientific Council, Accra, 1958. Pp. 173. (London: Secretariat, C.C.T.A./C.S.A., 1958.)

The most important development during the year, in respect of the Commission for Technical Co-operation in Africa, stressed in the Secretary-General's report, is the establishment of the Foundation for Mutual Assistance in Africa South of the Sahara. This Foundation will cover the provision of experts, advisers or the technical advice of specialized bodies; the provision of training facilities, for example, by organizing training centres in Africa of interest to several African countries; and the offer of equipment for research and education. However, the proceedings at the ninth meeting of the Scientific Council, the Secretary-General's report, with its survey of activities in soils and agriculture, in veterinary and medical science, in cartography, and in social, technological and economic matters, illustrate even more strongly the important place which the Scientific Council has already come to occupy in the development of Africa South of the Sahara and its inherent advantages in enabling European scientists, institutes and technical departments to continue to play their part in supplying the scientific and technical assistance needed in Africa. Neither the work of the Council nor its opportunities are as yet sufficiently known and the Bulletin, "Science-Afrique", the twelfth number of which appeared in September 1958, is a valuable supplement to this annual report for distributing information both about the Commission and the Council.

THERMAL REACTIONS OF HIGHLY FLUORINATED *CYCLO*HEXADIENES*

By B. GETHING, DR. C. R. PATRICK and PROF. J. C. TATLOW
Chemistry Department, The University, Edgbaston,
Birmingham 15

AND

DR. R. E. BANKS, DR. A. K. BARBOUR and A. E. TIPPING
Research Department, Imperial Smelting Corporation,
Avonmouth

HIGHLY fluorinated *cyclo*hexa-1 : 3 - and -1 : 4-dienes may be prepared from polyfluoro*cyclo*hexanes[1-3], by dehydrofluorination using aqueous alkali[1,2], ion exchange resins (Banks, R. E., Bevan, W. I., and Musgrave, W. K. R., unpublished results) or pyrolysis (Banks, R. E., and Tipping, A. E., unpublished results). The first aim of the work reported here was the conversion of fluoro*cyclo*hexa-1 : 4 -dienes into the more reactive and potentially more useful 1 : 3-diene isomers. Further, it was hoped that the 1 : 3-dienes might be sufficiently unstable with respect to the related fluorobenzenes to make possible new syntheses of aromatic compounds from them.

We now wish to report two new thermal reactions of highly fluorinated *cyclo*hexadienes by which both these objectives have been achieved. When these compounds are heated to temperatures in the range 250–600° C., in the absence of a reactive metal surface, isomerization is the predominant reaction. When the dienes are heated to similar temperatures in the presence of various metals, defluorination is the predominant reaction and fluorobenzenes are formed. These reactions may be carried out in a flow system or batchwise in pressure vessels.

We have found that both octafluoro*cyclo*hexa-1 : 3-diene and octafluoro*cyclo*hexa-1 : 4-diene are converted into a mixture of the dienes by passage through a tube heated to temperatures in the range 400–600° C. The best results were obtained using an unpacked nickel tube which had been 'aged' by carrying out several preliminary experiments, so as to avoid defluorination by the clean metal surface. The contact times required to bring about this and other isomerizations are of the order of 5 min. or less. The compositions of the mixtures produced are not greatly dependent on either temperature or contact times, and it is probable that they are close to equilibrium compositions. It is reasonable to suppose that the equilibrium constant for an isomerization will have only a small temperature coefficient, since the energy differences between the isomers should presumably be of the same order as those between conjugated and non-conjugated hydrocarbon dienes, and these would appear to be small. This is suggested by a comparison of tabulated values of heats of hydrogenation of olefins[4].

This isomerization reaction is general for highly fluorinated dienes. Thus, treatment of 1H-heptafluoro*cyclo*hexa-1 : 3-diene[1,2] at 260° C. yielded a mixture of the starting material, 1H-heptafluoro*cyclo*hexa-1 : 4-diene and 2H-heptafluoro*cyclo*hexa-1 : 3-

diene. Also, during additions of fluorine to certain 1 : 3-dienes for structure determination purposes, products have been obtained[2,5] which can arise only by a prior isomerization of the diene by a process of this type.

In the course of these investigations some evidence was obtained for a disproportionation reaction of fluorodienes since, for example, under certain conditions some decafluoro*cyclo*hexene together with hexafluorobenzene were formed from octafluoro*cyclo*hexa-1 : 3-diene. This aspect was not pursued, however, since a more interesting effect was observed if fluoro*cyclo*hexadienes were passed over clean metal surfaces at 400–600° C. Defluorination occurred readily, and aromatic fluoro-compounds were formed in good yield. These defluorination reactions are best brought about using tubes packed with nickel or iron gauze or turnings to increase the area of metal surface available, and with contact times of 2–5 min. As a consequence of the defluorination, the metal becomes coated with an impervious layer of fluoride and is deactivated, but the fluoride coating may be removed by the passage of hydrogen at temperatures greater than about 300° C.

Both isomers of octafluoro*cyclo*hexadiene were converted in good yield to hexafluorobenzene[6]. Small amounts of decafluoro*cyclo*hexene were also formed under certain conditions, apparently from the disproportionation reaction mentioned above. 1H-Heptafluoro*cyclo*hexa-1 : 3-diene gave, on defluorination, a mixture of pentafluorobenzene[7] and hexafluorobenzene, the last in smaller amounts, formed perhaps by dehydrofluorination of the isomeric diene with a >CHF group. 1H : 5H-Hexafluoro*cyclo*hexa-1 : 4-diene[5] was defluorinated to give chiefly 1 : 2 : 3 : 5-tetrafluorobenzene[8], together with some pentafluorobenzene. The high yields in which these benzenes are obtained, and the ease of preparation of some of the dienes, particularly the octafluorodienes, make this defluorination process a valuable method for the preparation of polyfluorobenzenes.

These reactions are novel in the field of organic fluorine chemistry. So far as we are aware, isomerizations of perfluoro-dienes have not been reported before and controlled defluorination processes of the type described here are rare, and have not been used synthetically.

Reactions were carried out by passing the diene through a nickel tube (1 in. diameter, 2 ft. 6 in. long) in a stream of nitrogen (2 l./hr.). The central portion of the tube was heated in an electric furnace. Temperatures were measured by a thermocouple placed on the outer wall of the tube in the centre of the heated zone. The products were condensed in a trap immersed in liquid air, and were analysed using gas chromatography. The components were separated by preparative-scale gas chromatography[9] and were identified by comparison of their infra-red spectra with those of authentic samples. For the isomerization reactions the best results were obtained after 'ageing' of the tube, that is, after several runs had been carried out.

Isomerizations. (1) Octafluoro*cyclo*hexa-1 : 4-diene (3·2 gm.) was passed through an 'aged' nickel tube heated to 450°. The product (2·9 gm.) was shown by analytical gas chromatography to contain 40 per cent of the *cyclo*hexa-1 : 3-diene.

(2) 1H-Heptafluoro*cyclo*hexa-1 : 3-diene (3·2 gm.) was passed through an 'aged' nickel tube heated to 260°. The products (3·1 gm.) were separated by gas chromatography to give 1H-heptafluoro*cyclo*hexa-1 : 4-diene (0·94 gm.), 1H-heptafluoro*cyclo*hexa-1 : 3-diene (1·28 gm.), and 2H-heptafluoro*cyclo*hexa-1 : 3-diene (0·21 gm.).

Defluorinations. In the following experiments the nickel tube was packed with Dixon gauze rings (1/16 in. × 1/16 in.). The metal became coated with metal fluoride during the defluorination and was regenerated between runs by passage of hydrogen at a rate of 5–10 l./hr. for about ½–1 hr. The effluent gas stream contained hydrogen fluoride. Excess hydrogen was then removed by nitrogen before the diene addition commenced.

(1) A mixture of octafluoro*cyclo*hexa-1 : 3- and 1 : 4-dienes (19 gm.) was passed in 3-ml. aliquots through the nickel tube packed with nickel Dixon gauze rings heated to 630–660°. After passage of each aliquot the metal was regenerated by hydrogen (5 l./hr. for 15 min.). The products were combined and separated by gas chromatography to give hexafluorobenzene (12·8 gm.) and decafluoro*cyclo*hexene (0·8 gm.).

(2) 1H : 5H-Hexafluoro*cyclo*hexa-1 : 4-diene (3·2 gm.) was passed through the nickel tube packed with nickel Dixon gauzes. The product (2·2 gm.) was separated by gas chromatography to give a mixture (1·7 gm.) shown by infra-red spectroscopy to contain 1 : 2 : 3 : 5-tetrafluorobenzene (80 per cent) and pentafluorobenzene (20 per cent). These two compounds cannot be resolved on the gas chromatography column packing used.

(3) 1H-Heptafluoro*cyclo*hexa-1 : 3-diene (3·2 gm.) was passed at 540° through the nickel tube packed with nickel Dixon gauzes. The product (2·0 gm.) was separated by gas chromatography to give hexafluorobenzene (0·64 gm.) and pentafluorobenzene (0·98 gm.).

(4) 1H-Heptafluoro*cyclo*hexa-1 : 3-diene (3·2 gm.) was passed through the nickel tube packed with steel Dixon gauze rings and heated to 570°. Of the product (2·2 gm.), a portion (1·7 gm.) was separated by gas chromatography to give hexafluorobenzene (0·56 gm.) and pentafluorobenzene (1·00 gm.).

(5) Octafluoro*cyclo*hexa-1 : 4-diene (5 gm.) was heated at 540° for 2¾ hr. in a nickel autoclave packed with mild steel tubes. The product (4·2 gm.) contained by weight hexafluorobenzene (40 per cent), decafluoro*cyclo*hexene (1 per cent), octafluoro*cyclo*hexa-1 : 3-diene (13 per cent) and starting material (46 per cent).

(6) Octafluoro*cyclo*hexa-1 : 4-diene (21 gm.) was passed at the rate of 12 gm. per hr. through a mild steel tube heated to 500°. The product (17·2 gm.) contained by weight, hexafluorobenzene (55 per cent), decafluoro*cyclo*hexene (6 per cent), octafluoro*cyclo*hexa-1 : 3-diene (12 per cent) and starting material (27 per cent).

A NEW GENERAL ROUTE TO AROMATIC FLUOROCARBONS*

By B. GETHING, Dr. C. R. PATRICK, Prof. M. STACEY, F.R.S., and
Prof. J. C. TATLOW
Chemistry Department, The University, Birmingham

IN the preceding article[1] it is shown that highly fluorinated *cyclo*hexadienes may be defluorinated by nickel or iron at high temperatures to give polyfluorobenzenes. It seemed possible that the substantially lower stability, under these reaction conditions of the alicyclic relative to the aromatic systems, was not confined to di-olefins. Accordingly, we have investigated fluoro*cyclo*hexenes (Coe, P. L., Patrick, C. R., and Tatlow, J. C., unpublished work) and shown that fluorobenzenes may be obtained from them in good yield. This communication describes the further extension of the defluorination reaction to saturated alicyclic fluorocarbons. Again, defluorination proceeded without difficulty, and we have made perfluorotoluene from perfluoromethyl*cyclo*hexane, perfluoroethylbenzene from perfluoroethyl*cyclo*hexane, perfluoro-*p*-xylene from perfluoro-1 : 4-dimethyl*cyclo*hexane, perfluorodiphenyl from perfluorodi*cyclo*hexyl, and perfluoronaphthalene from perfluorodecalin. Perfluorotoluene has been prepared before[2] in small yield by the addition of fluorine to trifluoromethylpentachlorobenzene followed by dechlorination, and perfluorodiphenyl has been made recently[3] by an Ullmann reaction on bromopentafluorobenzene.

The method of defluorination consists in passing the fluorocarbon in a stream of nitrogen through a metal tube packed with small pieces of iron gauze, and heated to a temperature in the range 400–600°. There would seem to be no objection to the use of other metal packings; for example, nickel also is effective. The metal fluoride produced in the defluorination process may be reduced to metal by the passage of hydrogen to enable further defluorinations to be carried out. We have used a furnace system much larger than that employed in our earlier work[1], in order to achieve longer contact times and to enable larger quantities of material to be handled.

The new compounds prepared have the properties anticipated and appear to be fairly resistant to simple chemical attack. The detailed exploration of their chemical properties is in progress. Evidence for their identity has been provided by determinations of molecular weight, based on the mass of the parent molecule ion formed on electron impact, using a mass spectrometer, and by their giving ultra-violet and infra-red spectra consistent with their structures. As described before[3], with sulphuric acid, perfluorotoluene gave pentafluorobenzoic acid.

We believe that this new synthetic method which we now describe represents a major contribution to fluoroaromatic chemistry. It provides the first general preparative route to the aromatic fluorocarbon series, and thereby opens up a new field. Only two overall stages are involved, namely, fluorination of a hydrocarbon followed by the defluorination. It also represents the first synthetic use for the saturated fluorocarbons, no controlled chemical reactions of which have been known hitherto. The process can probably be extended to cover the preparation of hydrogen-containing aromatic fluorides, as is the case (ref. 1, and Coe, P. L., Patrick, C. R., and Tatlow, J. C., unpublished work) with fluoro*cyclo*hexenes and hexadienes.

Alicyclic Fluorocarbons. These were prepared by the vapour-phase fluorination of toluene, ethyl benzene, *p*-xylene, diphenyl, and decalin, respectively, with cobaltic fluoride[5].

Defluorinations. The sample of material to be defluorinated was allowed to distil into a stream of nitrogen, and was carried through a nickel tube (diameter 2½ in., length 4 ft.), packed with small pieces of iron gauze and heated over most of its length by an electric furnace. Over the central portion (about 2 ft. in length) the temperature was sensibly constant to within about 5° C. during any experiment. The rate of flow of nitrogen measured, using a calibrated 'Rotameter' flowmeter, was maintained constant during each experiment. The reaction products were collected in a trap immersed in liquid air. After each reaction the metal fluoride produced by the defluorination process was reduced to metal by passage of hydrogen at temperatures between 300° and 600° C., enabling further reactions to be carried out. Excess hydrogen was then removed in the nitrogen stream.

Perfluorotoluene. Perfluoromethyl*cyclo*hexane (17·8 gm.) was passed through the reactor at 500° in a stream of nitrogen (2 l./hr.). The product (11·6 gm.) was separated by gas chromatography[6] to give perfluorotoluene (3 gm.), boiling point 102–3°, n_D^{20} 1·3680 (found: C, 35·5; F, 64·1; calculated for C_7F_8: C, 35·6; F, 64·4 per cent). Mass spectrometry: principal mass peaks: 236, C_7F_8; 217, C_7F_7; 167, C_6F_5; 148, C_6F_4; 129, C_6F_3; 69, CF_3. Perfluorotoluene (3·2 gm.) and concentrated sulphuric acid (2·5 gm.) were heated at 160° in a sealed tube for 12 hr. The product was poured into iced water, the solution made alkaline, filtered and extracted with ether. Acidification of the aqueous solution precipitated most of the product; the rest was isolated by continuous extraction with ether. Recrystallization from toluene – light petroleum (boiling point 60–80°) gave pentafluorobenzoic acid (1·8 gm.), melting point 104–105°, undepressed in admixture with an authentic specimen[3].

Perfluoroethylbenzene. Perfluoroethyl*cyclo*hexane (9·1 gm.) was passed in a stream of nitrogen (6 l./hr.) through the reactor at 490° and gave a product (4·9 gm.) which was separated by gas chromatography to give perfluoroethylbenzene (1·5 gm.), boiling point 114–115°, n_D^{20} 1·3620 (found: C, 33·2; F, 66·0; C_8F_{10} requires C, 33·6; F, 66·4 per cent). Mass spectrometry: principal mass peaks: 286, C_8F_{10}; 267, C_8F_9; 217, C_7F_7; 167, C_6F_5.

Perfluoro-p-*xylene.* Perfluoro-1 : 4-dimethyl*cyclo*hexane (9·1 gm.) was passed through the reactor at

---

* British Patent Application No. 35520/58 (November 5, 1958).

660° in a stream of nitrogen (2 l./hr.) and gave a product (5·9 gm.) which was separated by gas chromatography to give perfluoro-*p*-xylene (2·9 gm.), boiling point 117–118°, n_D^{19} 1·3610 (found: C, 33·9; F, 66·3 per cent). Mass spectrometry: principal mass peaks: 286, C_8F_{10}; 267, C_8F_9; 217, C_7F_7.

Perfluorodiphenyl. Perfluorodi*cyclo*hexyl (5·2 gm.) was passed through the reactor at 390° in a stream of nitrogen (2 l./hr.). The product (0·8 gm.) was recrystallized from benzene to give perfluorodiphenyl (0·5 gm.), melting point 67–69°. The value cited in the literature[3] was 70°; a mixed melting point of the two samples showed no depression, and their infra-red spectra were identical.

Perfluoronaphthalene. Perfluorodecalin (19·2 gm.) was passed in a stream of nitrogen (2 l./hr.) through the reactor at 500°, and gave a product which contained a solid. After being filtered off and recrystallized from benzene, this gave perfluoronaphthalene (5·8 gm.), melting point 86–87° (found: C, 44·3; F, 55·3 per cent; *M* (ebullioscopically in benzene) 260 ± 10. $C_{10}F_8$ requires C, 44·1; F, 55·9 per cent; *M*, 272).

We thank Dr. J. R. Majer for the mass spectrometric results.

FEEDBACK THEORY OF HYDROGEN OVERVOLTAGE

By J. F. CHITTUM

California Research Corporation, La Habra, California

INDICATIONS have been found that hydrogen overvoltage is related to hydrogen adsorption on cathodes[1]. This evidence leads me to suggest a feedback theory of hydrogen overvoltage based on the hypothesis that a metallic-bonded hydrogen – metal complex exists on the surface where hydrogen is evolved. This complex H(*M*) raises electron energy-levels on the metal side of a cathode[2], as shown in Fig. 1. (Where hydrogen is metallically bonded to the metal and φ of hydrogen as a metal is less than φ of the metal, the φ of the complex should be less than φ of the metal.) The hydrogen evolution reaction will not proceed at equilibrium potential unless the complex is maintained on most of the surface to make a pure electrode, and a zero current overvoltage is required to maintain the layer of complex.

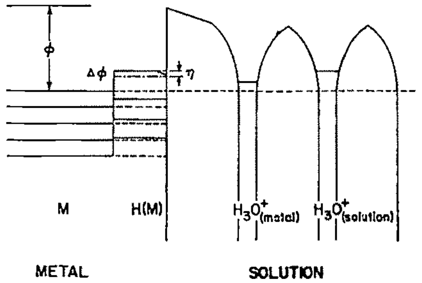

Fig. 1. Electronic energy levels at a cathode where the hydrogen evolution reaction occurs

Experimental data on hydrogen adsorption energy for hydrogen-covered metals are few. Beek[3] reports 18–20 kcal./mole for rhodium (and presumably platinum, palladium, etc.), and 10–13 kcal./mole for nickel, iron, tungsten and tantalum (and presumably many other metals). Estimated hydrogen adsorption energies for mercury, thallium, and lead covered with hydrogen are 6–8 kcal./mole. These energies are much lower for covered metals than for clean metals[3], and the latter energies are even partly reversed; that is, greater for tungsten and tantalum than for platinum and palladium. Decreased hydrogen adsorption energy with increased surface coverage may be due to residual covalent metallic bonding by *s* electrons of hydrogen and metal atoms after the combined *s*, *p*, *d* bonding[4] is used up. At least if the barrier-lowering hydrogen adsorption energy for covered metals is higher, overvoltage is lower, and overvoltage mechanisms can thereby be divided into three groups.

Steps in three hydrogen evolution reaction mechanisms for metal groups, *F*, *I*, and *S*, are shown in Table 1 for acid solutions. The *F* metals include mercury, thallium and lead with feeble hydrogen adsorption on covered surfaces. The *I* metals include cadmium to nickel, with intermediate hydrogen adsorption energies on covered surfaces. The *S* metals include platinum, palladium, rhodium, etc., with the strongest adsorption on covered surfaces. In Table 1, *x* under *F*, *I*, or *S* indicates a hydrogen evolution reaction step for metals in the group and *X* indicates the rate-determining step for each mechanism. Steps 1, 3 and 5 are so rapid that they do not influence

Table 1. OUTLINE OF STEPS IN THE FEEDBACK THEORY OF HYDROGEN OVERVOLTAGE IN ACID SOLUTIONS

Step No.	Steps in the hydrogen evolution reaction	Metal: *F*	*I*	*S*
1	$H_3O^+ (s) = H_3O^+ (M)$	*x*	*x*	*x*
2*a*	$H_3O^+ (M) + e^- (M) = H(M) + H_2O$	*X*		
2*b**	$\frac{1}{2} H_2(M) = H(M)$		*X*	*x*
3	$H_3O^+ (M) + e^- (H(M)) = H(M) + H_2O$	*x*	*x*	*x*
4	$2H(M) = H_2(M)$	*x*	*x*	*X*
5	$\frac{1}{2}H_2(M) = \frac{1}{2} H_2 (f)$	*x*	*x*	*x*

* Essential step in the feedback theory.

(*s*), in solution; (*M*), on or from metal; (H(*M*)), from chemisorbed hydrogen; (*f*), free; *x*, step in hydrogen evolution reaction; *X*, slow step in the reaction.

F metals: mercury, thallium and lead.

I metals: cadmium, beryllium, neodymium, aluminium, copper, gallium, iron, silver, etc.

S metals: platinum, palladium and rhodium.

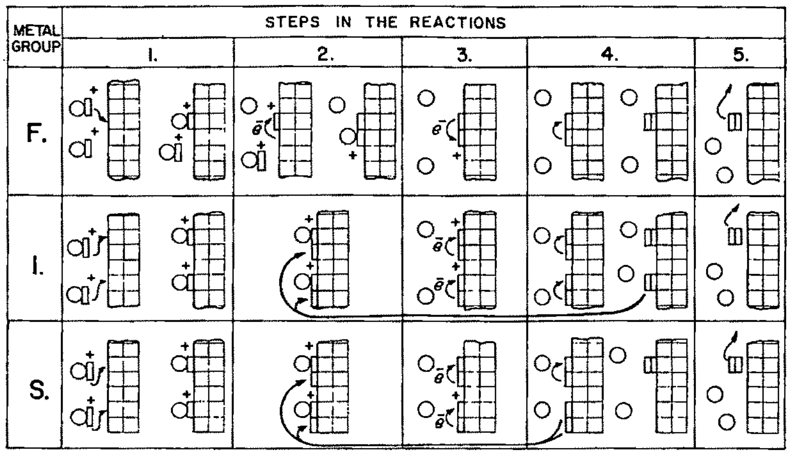

Fig. 2. Mechanisms of feedback theory for hydrogen evolution reactions. □, Metal atom; ○, water molecule; ▯, hydrogen atom; ▯+, hydrogen ion; ◫, hydrogen molecule; *e*, electron

overall rates. Steps 2*a*, 2*b*, and 4 only are sensitive to the energy of hydrogen bonding on covered surfaces.

Two competitive steps 2*a* and 2*b* are available for forming the complex: (*a*) step 2*a* occurs on *F* metals because hydrogen adsorption by 2*b* is slower, and (*b*) step 2*b*, the feedback part of the reaction, occurs on *I* and *S* metals at a rate that obviously depends on hydrogen adsorption energy. Step 2*b* is slower than step 2*a* for *F* metals; it is faster than step 2*a* for *I* metals, although slow enough to be rate determining; and it is so fast for *S* metals that it is not rate determining. Transitions in mechanisms may occur, so that *S* metals can act like *I* metals if the hydrogen adsorption energy decreases further. Step 2*b* is the reverse of step 4. This feedback then has the effect with *S* metals that only half the complex, produced in steps 2*b* and 3, reacts in step 4. Also, groups *I* and *S* differ in that, for *I* metals, step 2*b* is slower than step 4 so that step 2*b* must rebuild sufficient complex to maintain the current density; for *S* metals, step 4 is slower than step 2*b* and so step 4 is rate determining. Feedback differences are shown in Fig. 2 for areas initially deficient in the complex.

Significant experimental results about hydrogen evolution reactions are listed below with explanations from the feedback theory.

(1) *General observations.*

(*a*) Platinized platinum or any highly spongy metal has a low overvoltage because the spongy metals offer an enormous ratio of actual to measured surface area for combination of hydrogen.

(*b*) The hydrogen adsorption poisoning of metals results in increased overvoltage[5] because poisoning decreases the hydrogen adsorption energy.

(*c*) Hydrogen overvoltage increases with time (linearly for *F* metals, erratically for others)[6]. For *F* metals, build-up of the complex and charging of the condenser by step 2*a* should control this increase. For *I* and *S* metals, hydrogen adsorption energy decreases as surface coverage increases.

(*d*) Overvoltage changes with *p*H and the nature of the solvent[7] because hydrogen adsorption energy changes, and overvoltage decreases with increase in pressure for *I* metals[8] because rate of hydrogen adsorption increases. It is independent of pressure for *F* metals[9] because molecular hydrogen does not enter into the slow step.

(2) *The Tafel equation*, $\eta = A + B \log i$, *or* $i = i_0 \exp(\alpha VF/RT)$.

(*a*) Constant *A* is related to hydrogen adsorption because the rate of complex formation increases with the energy of hydrogen adsorption on covered metals.

(*b*) $\alpha = 2{\cdot}0$ and $B = 0{\cdot}029$ for *S* metals, whereas $\alpha = \frac{1}{2}$ and $B = 0{\cdot}114$ for other metals[10], because the slow step in the hydrogen evolution reaction on *S* metals is $2H(M) = H_2(M)$, and two reaction units form a unit product; whereas the slow step on *I* metals is $\frac{1}{2}H_2(M) = H(M)$, and half a reaction unit forms a unit product.

(*c*) i_0 for metals is a straight-line function[11] of φ because Δφ must increase with φ.

(*d*) At high current densities, polarization curves may show breaks indicating an increase in *B* in the Tafel equation up to that shown by *I* metals[12]. Breaks occur for some *S* metals because of decreased hydrogen adsorption energy upon more complete coverage, and for special metals (tungsten, tantalum, chromium and silver) because low current density polarization may be H controlled by hydrogen diffusion[13].

(3) *Hydrogen – deuterium separation.*

Hydrogen – deuterium separation factors divide metals into two groups: (1) *F* metals and possibly border-line metals which have factors about 3, and (2) other metals which have factors[14] of about 6. This division may occur because the activation energy for the reaction:

$$D + H_2O = HDO + H$$

is such as to give a separation factor of about 3 for a single chance of an exchange of *F* metals. The feedback step, 2*b*, for *I* and *S* metals would about double the chance of an exchange and double the factor.

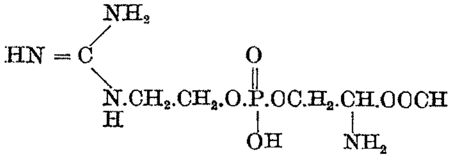
BIOCHEMISTRY OF LOMBRICINE

Occurrence of D-Serine in Lombricine

LOMBRICINE (guanidinoethyl seryl* phosphate) was isolated from earthworms (*Lumbricus terrestris*) by Thoai and Robin[1], and on the basis of paper chromatographic identification of the products of acid hydrolysis the following structure was suggested :



This structure has been confirmed by unequivocal synthetic routes using DL- and L-serine (Beatty and Magrath, following communication). For obvious reasons, it was assumed that the L-enantiomorph was present in the natural product ; but comparison with the synthetic product indicated that this was not the case (following communication). It has now been found that the D-isomer is actually present.

A sample of natural lombricine[2] (580 mgm.) was hydrolysed in a sealed tube in 6 *N* sulphuric acid at 110° C. for 24 hr. The serine present in the hydrolysate was isolated using ion-exchange and paper chromatography to give a final yield of 42 mgm. This material was free from guanidinoethyl phosphate and other hydrolysis products as shown by paper chromatography, using appropriate solvent systems and sprays. Recrystallization from aqueous ethanol yielded crystals ($[\alpha]_D = + 7{\cdot}40°$ in water ; melted with decomp. at 217°, uncorr.) which were identical in chromatographic behaviour in a number of solvent systems with D-serine.

A sample of the crystalline material was examined for its ability to function as a substrate for a crude preparation of sheep kidney D-amino-acid oxidase[3]. An authentic sample of L-serine was not oxidized by this preparation. In the case of the isolated material the amount tested (3·6 mgm.) yielded an oxygen uptake (over 45 min.) identical with that of an equivalent amount of authentic D-serine. The D-amino-acid oxidase was without effect on natural lombricine, synthetic DL-lombricine and synthetic DL-aminoethyl seryl phosphodiester[4].

Initial attempts to use an unfractionated hydrochloric acid hydrolysate product of lombricine as substrate for the enzyme failed because of the inhibitory quality of the hydrolysate. Whether this was due to some product(s) of hydrolysis or to some accidental contaminant is not known, but the result does cast doubt on the allocation of an L-configuration to the seryl moiety of aminoethyl seryl phosphodiester isolated from turtle muscle[5]. The evidence for this rests solely on the inability of a D-amino-acid oxidase preparation to oxidize the serine component of an unfractionated snake venom hydrolysate of the compound. If, as has been suggested[2], the aminoethyl seryl diester isolated from earthworms is the biological precursor of lombricine, it follows from the present results that, in the earthworm at least, the serine moiety of aminoethyl seryl diester would have a D-configuration.

The few claims for the presence of D-amino-acids in animal tissues have not met with general acceptance[6-8]. The configuration about the α-carbon atom of the 'alanine' moiety of octopine has been considered by some to be D-[7,8], but this conclusion seems unwarranted on the basis of the evidence available[9]. This report, therefore, constitutes the first occasion on which a D-amino-acid has been unequivocally shown to exist in animal tissue.

The presence of D-serine in lombricine suggests that this isomer may also be present in other compounds (for example, phospholipids and proteins) in the earthworm and, indeed, that it may not be the only D-amino-acid which occurs in this creature. It is hoped that work at present in progress will shed some light on these possibilities. The full report of this will be published elsewhere.

* In this and the following communication the term 'seryl' is used for convenience and refers to the '2-amino-2-carboxyethyl' group.

Synthesis of DL- and L-Lombricine

ON evidence based mainly on the paper chromatographic identification of the products of acid hydrolysis, it was concluded that lombricine was a mixed phosphodiester of serine and guanidinoethanol[1]. The amount of material isolated was small, and the configuration of the serine moiety was not investigated.

We wish to report the synthesis of DL- and L-lombricine by a route which confirms the structure allocated[1] and further indicates that the seryl residue in natural lombricine has the D-configuration. DL- and L-seryl aminoethyl phosphates were synthesized from the corresponding protected serine derivatives and N-carbobenzoxyethanolamine by a 'staggered' reaction with monophenylphosphorodichloridate, according to the method of Jones and Lipkin[2]. Subsequent reaction with O-methyl *iso*urea in aqueous solution at approximately *p*H 11 resulted in selective conversion of the aminoethyl residue in these compounds to a guanidinoethyl residue, giving DL- and L-lombricine in more than 70 per cent yield. Preliminary attempts to protect the α-amino group of the seryl moiety during the reaction with O-methyl *iso*urea, by forming a complex with copper (cf., for example, the preparation of arginine from ornithine[3]), led to extensive degradation of the molecule. Lombricine was found to be similarly unstable in the presence of copper, and the mechanism of the degradation is being investigated.

Both synthetic products crystallized from aqueous alcohol as colourless rods, the DL- melting at 216° C. (decomp.) and the L- at 226° (decomp.) ; natural lombricine[4], 224° (decomp.) (Thoai and Robin[1] give 223–24°). All samples showed discoloration before melting and the melting point varied appreciably according to the rate of heating and state of subdivision. Analysis : calc. for $C_6H_{15}O_6N_4P$: C, 26·6 ; H, 5·5 ; N, 20·8 ; P, 11·5 per cent ; found : DL- :

C, 26·5; H, 5·5; N, 20·9; P, 11·6; L-: C, 26·6; H, 5·6; N, 20·7; P, 11·6 per cent.

Both the synthetic compounds had R_F values identical with the natural product in a number of solvent systems. Similarly, the acid hydrolysates (6 *N* sulphuric acid, 110°, 8 hr.) of all three gave identical patterns of ninhydrin, α-naphthol-diacetyl[5] and molybdate[6] reacting spots, which corresponded with markers of authentic serine, guanidinoethanol and guanidinoethyl phosphate (synthesized in 84 per cent yield by reaction of ethanolamine phosphate with O-methyl *iso*urea in aqueous alkali).

pK_a values (potentiometric): DL-, 2·19, 8·9; L-, 2·16, 8·93; natural, 2·32, 8·9. The infra-red spectrum (potassium bromide disk) of the L-isomer was identical with that of natural lombricine, but differed significantly from that of the DL-compound.

For the L-isomer, $[\alpha]_D^{23\cdot5} = -13\cdot0$ ($c. = 0\cdot81$ in water), for the natural, $+14\cdot5$ ($c. = 0\cdot93$ in water), indicating a D-configuration in the serine moiety of natural lombricine.

The synthesis of D-lombricine by a route analogous to that described above is in progress. It may also be noted that a product having the expected chromatographic and chemical properties (stability to acid, spray reactions, etc.) of the naturally occurring phosphagen, N-phosphoryllombricine[1,7], has been obtained by reaction of N-phosphoryl O-methyl *iso*urea[8] with seryl aminoethyl phosphate under similar conditions.

Full details of this work will be published elsewhere.

We are indebted to Dr. H. Rosenberg for a sample of natural lombricine, and to Drs. J. E. Fildes, D. Perrin and E. Spinner for microanalyses, *pK* values and infra-red spectra, respectively. Phosphorus analyses were carried out by Mr. B. Thorpe.

STRUCTURE OF α-KERATIN

By DR. R. D. B. FRASER, T. P. MACRAE and DR. G. E. ROGERS

Division of Protein Chemistry, Wool Research Laboratories, Commonwealth Scientific and Industrial Research Organization, Parkville, N.2, Melbourne

THE examination of thin sections of developing hair[1,2] and fragments of chemically degraded wool[3,4] in the electron microscope has led to the view that α-keratin consists of microfibrils about 60–80 A. in diameter embedded in a matrix rich in sulphur. Confirmation of this structure by direct examination of intact, fully hardened keratin fibres is highly desirable but has been hampered by the difficulty of obtaining suitable sections. Mercer has alluded to a confirmation of this structure[5] but has not reported his findings in detail. We have found that by combining electron microscope observations with parallel studies of low-angle X-ray diffraction and measurements of infra-red dichroism, an elaboration of earlier notions of the molecular organization in α-keratin is possible.

A typical result obtained when reduced keratin fibres are treated with osmium tetroxide and examined in cross-section is shown in Fig. 1, in which fine fibrils about 70 A. in diameter are revealed by the greater concentration of osmium in the surrounding material. This shows at once that the microfibrils and matrix seen in developing hair retain their identity in fully hardened keratin. The nature and perfection of the microfibril packing are found to vary according to the origin of the keratin, being in some cases predominantly near-hexagonal (Fig. 1), while in others there is evidence of the spiral aggregates seen in developing hair[1,2,5].

In the tip of the quill of the North American porcupine and in human hair areas of near-hexagonal packing are interspersed with regions of alternating light and dark bands (Fig. 2). This may indicate the presence of a monoclinic or random layer lattice in which osmium penetrates readily along only one

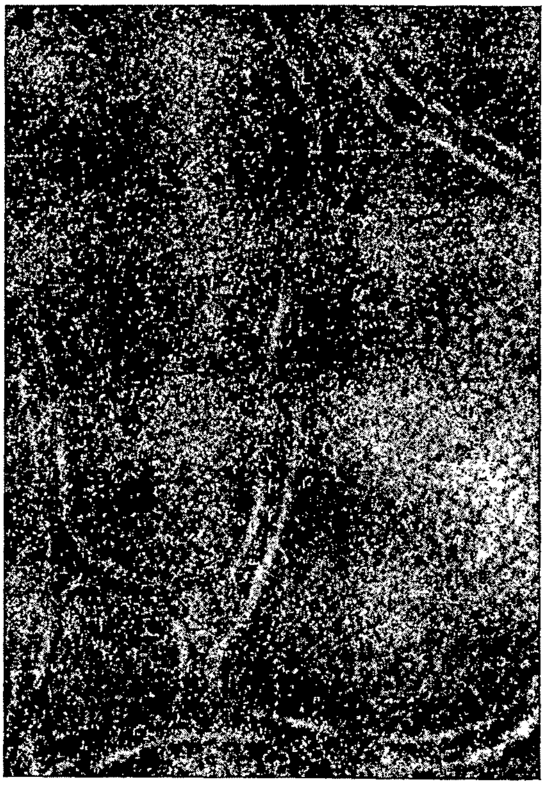

Fig. 1. Cross-section of a Lincoln wool fibre stained with osmium tetroxide after partial reduction of the disulphide linkages. Portions of several cortical cells are separated by dense bands of intercellular cement. (× 200,000)

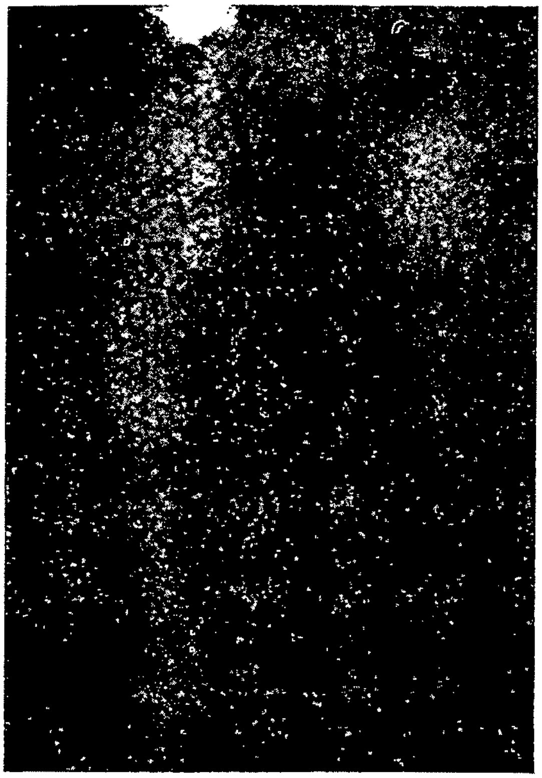

Fig. 2. Cross-section of North American porcupine quill-tip (*Erethizon* sp.) treated as in Fig. 1. The area of near-hexagonal packing of microfibrils adjoins a region where the microfibril-matrix complex appears as alternating light and dark bands. (× 200,000)

crystallographic plane, and would be consistent with the notion that the microfibrils are polarized, either physically or chemically, so that they tend to aggregate in sheets[1,4]. On the other hand, the alternating bands could be due to a hexagonal lattice viewed obliquely in crystallites where the direction of the microfibrils is not accurately perpendicular to the plane of the section. In Merino wool there is a sharp contrast between the orthocortex and paracortex, the microfibril packing is almost entirely near-hexagonal in the paracortex, while in the orthocortex spiral aggregates similar to those seen in developing hair predominate.

The diameter of the microfibrils is difficult to estimate accurately, but appears to be smaller in Merino than in Lincoln wool. Whether this is due to a variation in the extent to which osmium penetrates the microfibril or to a genuine structural difference is uncertain.

The equatorial low-angle X-ray diffraction pattern of α-keratin is complex but is dominated by three maxima which may be interpreted as lattice reflexions, or combinations of lattice reflexions, in which the intensity is determined by both the shape of the microfibril and the difference in scattering power between microfibril and matrix[6]. When wool, hair or quill-tip is treated with osmium tetroxide these reflexions are intensified[7], but an even greater intensification may be obtained by prior reduction of the ($A + B$) fraction of the cystine residues. As the osmium is now known, from the electron micrographs, to be concentrated in the matrix after this treatment, it is likely that the effects are additive, that is to say, the osmium is also preferentially deposited in the matrix in non-reduced fibres. The contrast in this case does not appear to be sufficient, however, to be detected by electron microscopy.

There is a good deal of indirect evidence to suggest that the microfibrils are the entities responsible for the high-angle X-ray diffraction pattern of α-keratin and that the matrix is largely non-crystalline. The present work lends considerable support to this view as the deposition of osmium in the matrix either before or after reduction has virtually no effect on the high-angle pattern. Osmium tetroxide reacts with a rather wide variety of chemical groupings[8] and the preferential deposition of osmium in the matrix even before reduction would be consistent with a less well-organized arrangement of polypeptide chains in this component.

The additional deposition of osmium in the matrix following reduction of the ($A + B$) fraction[9] of the cystine residues suggests that this fraction is concentrated in the matrix. There is a considerable body of chemical evidence which shows that proteins of much higher cystine content than whole wool may be extracted, and the present work supports the view that these originate in the matrix. Further support for this conclusion is obtained from the observation that reduction and labelling of the ($A + B$) cystine with the specific reagents methyl mercury iodide and neohydrin lead to an intensification of the low-angle equatorial reflexions, although this is much less than with osmium.

The spacing of the innermost equatorial reflexion has been suggested previously to be the distance between adjacent layers in spiral aggregates or the 10·0 reflexion of the areas of hexagonal packing[6]. This spacing has now been measured with greater resolution than in previous work and is found to vary with the origin of the keratin as shown in Table 1. It is interesting to note that the spacing in untreated hair is considerably greater than that of quill or wool and may be correlated with the higher cystine content of this material. The small but definite increases observed when keratin fibres are reduced and treated with osmium are also given. The measured spacings in these specimens agree sufficiently well with those determined directly from the electron micrographs to confirm the interpretation given previously.

In simple polymers such as cellulose, crystallinity is a well-defined property which has an important bearing on its physical properties and may be investigated by X-ray diffraction methods, water absorption isotherms and by studying the extent to which the potentially replaceable hydrogen atoms in the structure are replaced by deuterium[10]. The term crystallinity is also used in discussing the properties of keratin, but certain important differences between the significance of the term in the two instances

Table 1

Keratin	Cystine content as percentage total nitrogen	Approximate spacing of innermost equatorial reflexion measured *in racuo* over phosphorus pentoxide	
		Untreated	Reduced and treated with OsO_4
Porcupine quill-tip	6·8	77	82
Lincoln wool	6·8	79	82
Merino wool	7·9	80	87
Human hair	12·0	87	95

emerges from the present work. Although precise measurements are difficult to make, preliminary studies suggest that the fractional increase in the innermost equatorial X-ray spacing when dry keratin fibres are hydrated is about the same as the fractional increase in the fibre diameter. In contrast, the increase in the spacing of the high-angle maximum is only about 5 per cent. It may be concluded, therefore, that the microfibril lattice expands to a greater extent than does the interchain distance within the microfibrils. This suggests either that the hydrophilic side-chains are concentrated in the matrix or that a proportion of the sorption sites located within the microfibrils are inaccessible. A similar conclusion may be drawn from our own[12] and other studies[13] of the hydrogen – deuterium exchange reaction by infra-red spectroscopy, in which the inaccessible peptide linkages have been shown to be concentrated in the oriented regions of the fibre. In addition, we have found that supercontraction in cuprammonium hydroxide, which from X-ray evidence is known to disorganize the internal structure of the microfibrils, increases accessibility, whereas reduction and substitution of the $(A + B)$ fraction of the cystine, now presumed to be concentrated in the matrix, has little effect.

As regards sorption of water, accessibility to deuterium and high-angle X-ray diffraction, the microfibrils appear to behave very much like the crystallites of simpler polymers, but so far as we are aware there is no evidence that they are true crystallites in the crystallographic sense. It is more likely that the asymmetric unit is, in fact, an approximately cylindrical assembly of polypeptide chains about 70 A. in diameter and 200 A. long. At present there does not appear to be any evidence of the arrangement of the polypeptide chains within the asymmetric unit apart from the general conclusion that they occur as groups of compound α-helices[14].

By combining estimates of microfibril diameter obtained from electron micrographs with the spacing of the innermost reflexion of the low-angle equatorial X-ray pattern in untreated keratins, a crude estimate of the relative proportions of microfibril and matrix may be obtained if the packing is assumed to be hexagonal. Estimates obtained in this way vary considerably but suggest that the matrix constitutes between a quarter and a half of the cortex in wool. If the cystine in wool is, in fact, concentrated in the matrix, it should therefore account for about 12–24 per cent of the nitrogen in the matrix protein, assuming equal densities and mean residue weights in the microfibril and matrix. Protein fractions with cystine contents in this range have, in fact, been isolated from wool and probably originate in the matrix[15].

It has been suggested that the bulky side-chains in wool are confined to the amorphous regions[16], and if these are identified with the matrix the upper estimate of its proportion is, in fact, sufficient to accommodate all the cystine, arginine, aspartic and glutamic acids, lysine and tyrosine. However, analyses of the proteins rich in sulphur[15] do not support such a heterogeneous distribution of composition. Evidence has also been obtained which indicates that a significant proportion of the tyrosine is regularly disposed along the length of the microfibril[7], which again does not accord well with this view. As the interchain spacing in the microfibril expands on hydration of the fibre[11] it may be possible for reagents to enter the microfibrils to some extent, in which case the relegation of residues such as tyrosine and lysine to the matrix on the score of their complete accessibility[18] to chemical reagents may not be justified.

In conclusion, the close analogy between globular protein crystals and α-keratin may again be emphasized[17]. In a sense the matrix in α-keratin may be regarded as the counterpart of water of crystallization in globular protein crystals, and this analogy is reinforced by the way in which the intensities of the low-angle X-ray reflexions in both cases vary with the electron density in the spaces between the organized particles, and also by the effect of water-content on the perfection of the X-ray diagram[17]. The replacement of water, or rather dilute protein gel, between the microfibrils by matrix substance is, in fact, observed during biosynthesis of keratin fibres[1,2].

The extent to which the spiral aggregates, formed prior to keratinization, persist in the keratinized fibre varies considerably. The extent of rearrangement to a near-crystalline form is very advanced in quill-tip and virtually complete in the paracortex of Merino wool, whereas in the orthocortex it is only rudimentary. It appears, therefore, that the process of keratinization inhibits the crystallization of the microfibrils at various incomplete stages depending upon the origin of the keratin. The transition from the spiral aggregate to the hexagonal or monoclinic forms is probably related to the greater stability of the latter as the size of the aggregate increases. It may be shown, by the same argument as used by Crick[18] in discussing the formation of compound helices, that stable aggregates of rods with helical grooves, or helical lines of greatest attraction, can be formed in which successive layers lie on the circumferences of concentric cylinders. The contacts between cylinders in the same layers and adjacent layers can be made close to optimum provided the angle of pitch increases by a constant amount in successive layers. The stability, however, decreases rapidly when the pitch angle becomes appreciable, and with further growth a reorganization to a hexagonal form becomes the more stable arrangement.

Thanks are due to Drs. H. Lindley and S. J. Leach for helpful discussions, and to Miss C. M. McKinnon for technical assistance.

LETTERS TO THE EDITORS

GEOLOGY and GEOPHYSICS

Isotopic Composition of Lead from British Mineral Deposits

It is well established that in many cases there is an approximate relation between the isotopic composition of common lead and the geological age of the lead-bearing mineral deposit, especially when the latter is closely connected with major igneous activity. An isotopic study of several British lead ores (mainly galena) has given preliminary results which clearly indicate the usefulness of the method from a geological point of view. In the case of the British deposits the geological setting is usually well established, while Dunham has reviewed the structural and field evidence for their age[1].

The model chosen for calculation of ages from the isotopic composition is that of Houtermans[2] and Geiss[3], using Patterson's values[4] for the isotopic composition of primeval lead from iron meteorites and modern lead from ocean sediments, together with generally accepted values of uranium and thorium decay constants (see footnote to Table 1).

Isotopic measurements were carried out with a Metropolitan-Vickers *MS*5 solid-source mass spectrometer using the triple-filament volatilization technique on precipitated lead sulphide. The observed abundance ratios were multiplied by the square root of the mass ratio to correct for mass discrimination in the electron multiplier.

Results are presented in Table 1. Within each group, well-located samples have been chosen from a representative area. In most cases the observed ratios lead-206/lead-204, lead-207/lead-204, lead-208/lead-204 agree within experimental error for samples within a given group. The error of each average indicated for these ratios in columns 3, 4 and 5 represents a 95 per cent confidence-level.

The errors given for the average model age in column 6, as well as for the uranium-238/lead-204, thorium-232/uranium-238 ratios, are calculated from the experimental error only. The absolute error is not yet known with certainty, but is thought to lie within similar limits. Absolute age-determinations on uranium minerals from some Cornwall lodes should provide a useful reference point in this connexion.

With the assumptions made in the model, the proved Permo-Carboniferous (Hercynian) ores of south-west England give a model age of 280 ± 30 million years, which is somewhat higher than the average value of 220 million years assumed by Holmes for Hercynian leads[5]. However, in view of the fact that some extension of the Holmes time-scale[6] is indicated by recent potassium–argon work in this laboratory on Hercynian and Caledonian igneous rocks from Great Britain[7], it was decided to retain the higher value for the time being.

There is striking agreement in the model ages and geochemical ratios (columns 7 and 8) between south-west England, the northern Pennines and the Lake District. This suggests that the mineralization in all three areas is connected with Hercynian igneous activity[1,8] and derived from similar source material. The suggestions that: (*a*) the northern Pennine mineralization is Tertiary in age[9]; (*b*) the greater part of the Lake District mineralization is either connected directly with the known Caledonian intrusions[10] or Tertiary in age[9], are not supported by the isotopic data.

Two measured samples from the Lake District have not been included in group 3. These come from the Shap Blue Rock Quarry, Westmorland (kindly supplied by Dr. R. J. Firman), and from the Ruthwaite Lodge Vein, Grisedale, near Patterdale, Westmorland, respectively. The former is possibly associated with the Shap Granite itself[11] and gives a higher model age (370 million years) than any other sample from group 3. In contrast, the Ruthwaite Lodge Vein sample gives a very low model age (80 million years). Furthermore, one sample from Devon has not been included in group 1. This is from the Combe Martin Lode, north Devon, and has a higher model age (360 million years) and, possibly,

* Values extrapolated to the present time. Average errors ± 0·1 and ± 0·05 respectively

Decay constant of ^{238}U = 1·541 × 10^{-10} year^{-1}; decay constant of ^{235}U = 9·72 × 10^{-10} year^{-1}; modern ratio $^{238}U/^{235}U$ = 137·8. Isotopic composition of lead from iron meteorites (ref. 4): 206/204 = 9·50, 207/204 = 10·36, 208/204 = 29·49. Isotopic composition of lead from modern ocean sediments: 206/204 = 18·93, 207/204 = 15·73, 208/204 = 38·80. Age of Earth = 4·50 × 10^9 years.

a different geological history than other deposits of south-west England (Dunning, F. W., personal communication). These samples will be discussed more fully elsewhere.

In contrast, groups 4 and 5 have considerably higher model ages than groups 1, 2 and 3, suggesting that the deposits owe their origin to Caledonian activity. Significant differences in the uranium-238/lead-204 and thorium-232/uranium-238 ratios are also found, implying slightly different geochemical environments.

The galenas of group 5 belong to the small, distinctive mineralization associated with Caledonian granites in the Abergairn and Ballater areas of Aberdeenshire[1]. Three galena samples of group 4 occur in the high-temperature gold–copper deposits of the Harlech Area, north Wales, which Dunham[1] was tempted to assign to the Caledonian epoch, although positive evidence was lacking. The two remaining samples come from typical Plynlimmon localities, some miles east and north-east of Aberystwyth where, significantly, the veins occur in Silurian strata. O. T. Jones[12] had already suggested that in this area some of the vein-fractures were contemporaneous with Caledonian folds.

More isotopic analyses of British and Irish common leads are in progress; detailed results and their bearing on geological problems will be published in due course.

Grateful acknowledgment is made to Dr. A. McGregor, Dr. P. A. Sabine and F. W. Dunning, of H.M. Geological Survey, as well as Prof. K. C. Dunham, Prof. F. H. Stewart and A. W. G. Kingsbury, for donation of the specimens used in this work. The work forms part of the geological age and isotope research programme being carried out in this Department under the general direction of Prof. L. R. Wager and Dr. E. A. Vincent.

Palæomagnetism of Certain Rocks from Newfoundland

DURING the course of a visit to Newfoundland in the summer of 1957, orientated rock samples were collected by members of the Durham University Exploration Society. Pre-Cambrian rocks near St. Johns and the Mississippian Codroy rocks north of Robinson's River were sampled.

The Pre-Cambrian rocks were obtained from two localities, Signal Hill and Blackhead, on the Avalon Peninsula. The collection made on Signal Hill where the beds dip steeply eastwards represented an older horizon than the less-steeply dipping rocks collected from Blackhead, for it is clear from both graded and current bedding that the rocks are not inverted. Lithologically there is no marked difference between the two areas, the sediments at both places consisting of hard, purplish sandstones although the stratigraphical separation may be of the order of 8,500 ft.

Table 1. MEAN DIRECTION OF MAGNETIZATION OF NEWFOUNDLAND SAMPLES

Formation	Declination	Inclination	α	$\varkappa$	N	S	Mean intensity of magnetization
Codroy group	166°	+8°	8·4	38	36	9	$16{\cdot}2 \pm 11{\cdot}4 \times 10^{-6}$
Pre-Cambrian	262	+39	13·3	8	76	19	$14{\cdot}4 \pm 7{\cdot}9 \times 10^{-6}$
Blackhead collection	232	+51	9·9	25	40	10	—
Signal Hill collection	283	+20	11·3	21	36	9	—

α, Radius of the circle of confidence; $\varkappa$, a measure of precision; N, number of measurements; S, number of samples measured.

Table 2. POLE POSITIONS CALCULATED BEFORE AND AFTER 20° ROTATION

Formation	Site	Ancient pole	$d\psi$	$d\chi$	Re-oriented ancient pole
Codroy group	59 W. 48 N.	139 E. 43 N.	4·3	8·5	113 E. 44 N.
Pre-Cambrian	53 W. 47 N.	122 W. 11 N.	9·6	16	136 W. 23 N.

Signal Hill collection	53 W. 47 N.	142 W. 16 N.	6·2	11·8	163 W. 29 N.

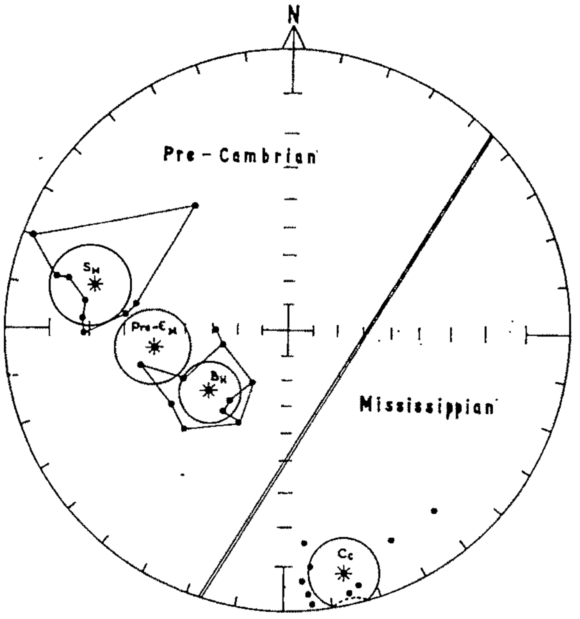
$d\psi$ and $d\chi$, semi-axes of the oval of confidence of the pole positions.

The Mississippian rocks, some 1,200 ft. thick, comprise a lower deltaic series, the Anguille group, overlain by the Codroy group of homogeneous, fine-grained, hard red unfossiliferous sandstones. The beds dip steeply north-west, and their structural and stratigraphical relationships have been studied by Baird.

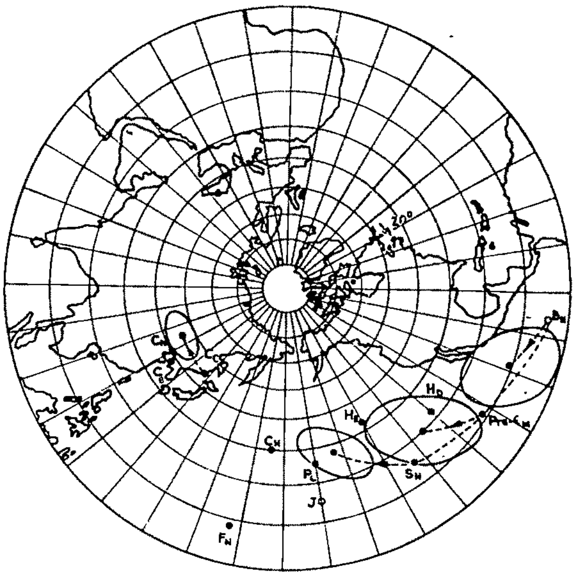
The rocks were cut and measured under an astatic magnetometer in the manner described by Collinson *et al.*[1]. The calculation of the relevant mean directions, pole positions and statistics, following the methods of Creer *et al.*[2] and Fisher[3], are given in Fig. 1*A* and in Tables 1 and 2. In these calculations the means of four measurements per sample are used and not individual measurements.

The difference between the mean directions of the two Pre-Cambrian collections is quite marked, and consequently all relevant calculations have been made for each set as well as the means for the whole group. In view of the size of sample and the uncertainty of the stratigraphic relationship of the two areas it would seem unwise to attribute much significance to this result. It is of interest, however, that this group mean pole position is fairly close to one of the Hakatai Shale results quoted by Creer *et al.*[2], and quite different from the Keweenawan of Du Bois[4].

The pole position obtained from the lower Carboniferous rocks lies considerably to the east of those quoted by Creer *et al.*[2] and Martinez and Howell[5]. This difference disappears if it could be assumed that in post-Carboniferous times there had been a relative anticlockwise rotation of Newfoundland with respect to the rest of North America. This is illustrated in Fig. 1*B*, where a rotation of 20° has been assumed.



A



B

Fig. 1*A*. Stereographic plot of the directions of magnetization of Pre-Cambrian and Carboniferous (Mississippian) samples from Newfoundland. (Signal Hill and Blackhead samples separately linked.) All north-seeking poles point down. * represents the mean direction enclosed within the circle of confidence

Fig. 1*B*. Plot of pole positions of American Pre-Cambrian and Carboniferous rocks, illustrating the effect of a 20° rotation on the Newfoundland samples. Ellipses of confidence are drawn around the Newfoundland pole positions.
Pre-ε_M mean of all Newfoundland Pre-Cambrian (S_H, Signal Hill; B_H, Blackhead collections). H_{D_1} and H_R pole positions of Hakatai Shale samples according to Doell and Creer *et al.* P_L, C_H, FN, J, Portage Lake, Copper Harbour, Freda and Nonesuch, and Jacobsville divisions of the Middle and Upper Keweenawan. (Jacobsville and Blackhead poles are south of the equator.) C_C pole position of Codroy samples; C_N and C_B pole positions of Naco Sandstone and Barnet Shale samples

The effect of such a rotation upon the Pre-Cambrian pole positions is to improve greatly the agreement with the rest of North America. The group mean position approaches those obtained by Runcorn and Doell for the Hakatai Shales, while the new pole position of the Signal Hill samples even suggests possible correlation with the Portage Lake horizon of the Keweenawan[4]. This is clearly seen in Fig. 1*B*, where the re-oriented pole positions are enclosed within their ellipses of confidence.

This suggested rotation is based entirely on palæomagnetic considerations; whether or not it is entirely fortuitous depends upon geological considerations, and it appears (Westoll, T. S., personal communication) that such a movement has been suggested by some geologists.

The assistance of Prof. T. S. Westoll, Drs. D. M. Baird, N. D. Opdyke and members of the Durham University Exploration Society is gratefully acknowledged. Thanks are also due to A. Major and W. Rutherford for their help in the preparation and measurement of the rocks.

PHYSICAL SCIENCES

Anomalous Night-Time Reception of a Major Solar Radio Burst

During the early morning hours of March 8, 1958, the planet Jupiter was under observation by a total of five different receiving arrays at the University of Florida Radio Observatory. Two of these arrays operated at a frequency of 18 Mc./s., two at 22·2 Mc./s., and one at 27·6 Mc./s. Both pen recording and aural monitoring of the signals by an observer were employed. At 0235 U.T. an unusual event began simultaneously on all five channels, consisting of a single very intense burst of noise which slowly rose to a maximum, and even more slowly declined over a total period of about 2 min. During this interval the observer was able to obtain an excellent record of the polarization of the disturbance with the 22·2 Mc./s. polarimeter, which was kept in stand-by condition during all periods of observation.

The outburst differed from typical Jupiter noise in a number of respects: (1) the relatively smooth rise and fall of the signal was slower by at least an order of magnitude than any previously observed single Jupiter pulse[1]; (2) no Jupiter pulse had been observed at this Laboratory simultaneously on all three frequencies; (3) analysis of the polarimeter record showed the burst to be polarized in the left-hand elliptical sense, whereas all the Jupiter noise analysed here had shown right-hand circular or elliptical polarization. Although the event had occurred more than four hours prior to sunrise, it was inescapable that it displayed many of the characteristics of a solar burst, rather than a Jupiter pulse.

Subsequent correspondence with C. A. Shain in Australia disclosed that a major solar burst had indeed been observed at stations in Potsdam, Uccle, Nogaya, Tokyo and Sydney, on the sunlit hemisphere of the Earth, at the same instant as the event described above. Unfortunately, all the available observations were at frequencies much higher than those of the Florida station; but the observations made at Sydney at 108 Mc./s. were off-scale and were described as possibly "one of the largest bursts ever observed near this frequency". It seems clear, then, that the event observed in Florida was this major solar burst, propagated by some means far into the dark hemisphere of the Earth.

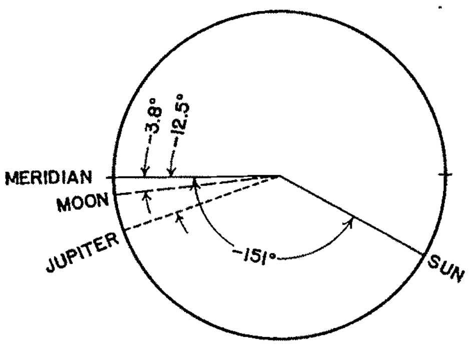

Fig. 1. Polar diagram showing the relationships between the bodies of interest

The relevant relationships are shown in Fig. 1, which is a polar diagram of the Earth, with the directions of the bodies concerned shown in terms of hour angle. It should be remarked in connexion with this diagram that the antenna patterns are centred on the meridian and are approximately 30° wide in the east–west direction. Of interest is the fact that the Moon was actually closer to the centres of the antenna beams than was Jupiter at 0235 hr. U.T., so that a lunar reflexion of the burst immediately suggests itself. If one assumes a lunar reflexion coefficient of 0·15 and a directivity factor of 4 due to scattering[2], the attenuation factor for a lunar echo would be about 10^{-5}. The peak flux recorded at Florida at 18 Mc./s. was off-scale at approximately 6×10^{-20} watt m.$^{-2}$ (c./s.)$^{-1}$, suggesting that at this frequency the directly received burst would have had an intensity of about 6×10^{-15} watt m.$^{-2}$ (c./s.)$^{-1}$ at 18 Mc./s. The Australian observers estimated the intensity as being of the order of 10^{-17} watt m.$^{-2}$ (c./s.)$^{-1}$ at 108 Mc./s. Although no direct comparison can be made because of this large difference in frequency, the orders of magnitude do not seem entirely to exclude the possibility of a lunar reflexion. (We would welcome intensity data from this event from any station which happened to record it at a frequency nearer 18 Mc./s.).

The other possibility is, of course, that the radiation penetrated the ionosphere through an anomalous 'thin' spot in the daylight hemisphere, and was then propagated around the Earth by the usual modes of transmission. In this connexion, Shain was kind enough to point out to us the curious focusing at the antipodal point of the 40-Mc./s. signal from *Sputnik I*, which was reported by Wells[3].

Operation of the Florida Radio Observatory is assisted by funds from the National Science Foundation, the U.S. Army Office of Ordnance Research and the Office of Naval Research.

Polynomial Representation of Steam Tables

THE mechanization of computation concerning steam plant design has been greatly frustrated by the difficulty of having to use steam tables. An experiment carried out using the University of Manchester Mark I digital computer a year ago showed that while it was quite possible to have the whole contents of the Keenan and Keyes table[1] stored within the machine, calculations of turbine condition lines and cycle efficiencies were slowed down considerably by the business of searching through the table for particular entries. A major advance in the mechanization of steam-cycle calculations has now been accomplished by the derivation at Risley of sets of polynomials which accurately represent the thermodynamic properties of steam.

The steam tables tabulate enthalpy, entropy and specific volume of dry steam as functions of pressure and temperature. It has been found possible to fit each of these thermodynamic functions by a single polynomial in $U = \log p$ and:

$$V = \frac{B\{(t + A)^{-1} - C\}}{B - \log p} \qquad (1)$$

where t is temperature in degrees F., and p is pressure in lb./sq. in. and A, B, and C are constants.

The temperature-range covered by these approximations is from saturation to 1,600° F. The pressure-range is from 1 lb./sq. in. in the case of enthalpy and specific volume and from less than 5 lb./sq. in. in the case of entropy up to the critical pressure.

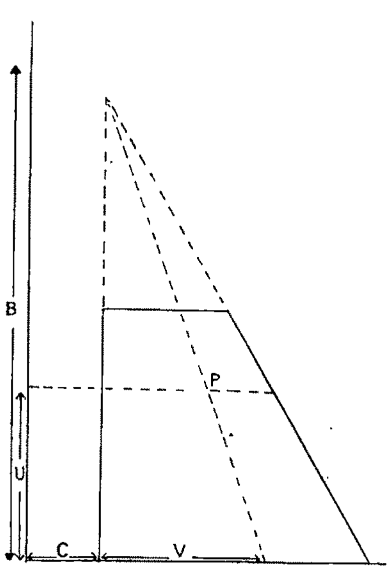

Fig. 1

It is essential to choose the arguments, U and V, of the polynomial so that points outside the saturation line are not included in the rectangle defined by the ranges of U and V. It was found that, with a suitable choice of A, a plot of $\log p$ against $1/(A + t)$ at saturation gives an excellent straight line over the whole pressure-range. Thus for variables $\xi = \log p$, $\zeta = 1/(A + t)$ the steam functions are defined over a trapezium (Fig. 1).

A second transformation, $U = \xi$, $V = \dfrac{\zeta - C}{B - \xi}$ transforms the trapezium into a rectangle, which does not contain points from outside the tables. The polynomials were then obtained by a two-dimensional modification of the method described by Lanczos[2]. The functions were fitted by:

$$F(x,y) = \sum_{k=0}^{9} \sum_{l=0}^{9} C_{kl}\, T_k(x)\, T_l(y) \qquad (2)$$

$$\text{where } x = a_1 U + b_1, \quad -1 \leqslant x \leqslant 1$$
$$y = a_2 V + b_2, \quad -1 \leqslant y \leqslant 1$$

and T_n is the Chebyshev polynomial of order n.

$$C_{kl} = A_{kl} \sum_{\alpha=0}^{9} \sum_{\beta=0}^{9} f(x_\alpha, y_\beta) \cos\frac{k\pi}{20}(2\alpha + 1) \cos\frac{l\pi}{20}(2\beta + 1) \qquad (3)$$

where, for $i \neq 0$, $j \neq 0$,

$$A_{00} = \frac{1}{100},\ A_{i0} = A_{0j} = \frac{1}{50} \text{ and } A_{ij} = \frac{1}{25} \qquad (4)$$

$$\text{Also} \quad \left.\begin{aligned} x_\alpha &= \cos\frac{\pi}{20}(2\alpha + 1) \\ y_\beta &= \cos\frac{\pi}{20}(2\beta + 1) \end{aligned}\right\} \qquad (5)$$

The values of the function at (x_α, y_β) were obtained by two-dimensional interpolation in the steam tables. To facilitate this, the variables were slightly modified so that the points required near the saturation boundary were not at the very edge of the tabulated values. The entropy function begins to change rapidly with p at pressure less than 4 lb./sq. in., and if the tables are fitted from 1 lb./sq. in. upwards, the high-order coefficients in (2) do not become negligible. However, by excluding pressures less than 5 lb./sq. in. from the region fitted, this difficulty was overcome. Finally (2) was transformed to give a simple polynomial in U and V.

For use in a digital computer all that need be stored are the coefficients of the polynomials, which occupy a space less than 1½ per cent of that required by the full steam table, and 'table look-up' is completely eliminated. The necessary routines have been prepared for the Risley *Mercury* computer and the values of the coefficients of the polynomials will appear elsewhere.

Ductility of Rhodium

Although rhodium is a face-centred cubic metal which should possess numerous planes and directions of slip it is, at room temperature, an extremely difficult metal to form into strip and wire. Usually rhodium is hot-worked, the working temperature being gradually reduced during successive stages until the metal develops a fibrous structure, when at thin gauges it can be subjected to moderate cold-working operations.

The reason for the poor room-temperature ductility of rhodium is not known, but has been ascribed to impurities, although, from experiments using high-purity rhodium, Bale[1] concludes that it is more probable that rhodium is subject to deformation mechanisms different from those for other face-centred cubic metals.

It appears unlikely that in a face-centred cubic metal slip will occur preferentially on planes other than (111), since this would involve a non-statistical distribution of dislocations with Burgers vectors having only very small components in this plane. However, segregation of impurity atoms around dislocations might produce an atmosphere effect greatly increasing the resolved shear stress for glide; this would be reduced at high temperatures, when diffusion would enable the atmosphere to move with the dislocation and such a process would presumably result in a yield-point being observed. Another possibility is that slip is finer in rhodium and that hardening is accentuated by intersections, impurities and point defects.

If any one of these hypotheses is correct, it might be expected that a single crystal of rhodium would be of similar low ductility to the polycrystalline material. If, however, lack of ductility is due to grain-boundary weakness or to the locking of dislocations at crystal boundaries, because of impurities or for other reasons, such a single crystal might be expected to exhibit a greater degree of ductility and a lower rate of strain-hardening than when in polycrystalline form.

Consequently, as a preliminary to a more comprehensive investigation on the deformation of rhodium, a single-crystal bar of the metal was prepared by the electron-bombardment floating-zone melting technique[2,3].

The bar was made from rhodium of normal commercial purity (Table 1), the starting material being an annealed hot-swaged bar, 0·165 in. diameter and hardness 180 diamond pyramid number, prepared from a compact sintered *in vacuo* and heated during swaging in an atmosphere of hydrogen. During zone melting, a considerable amount of evolution of gas occurred and seventeen passes of increasing bombarding power were necessary before the bar could be

Table 1. SPECTROGRAPHIC ANALYSIS OF RHODIUM

	Original bar (per cent)	Zone-melted bar (per cent)
Platinum	< 0·01	< 0·01
Palladium	0·01	0·0001
Ruthenium	0·026	0·026
Iridium	0·08	0·08
Iron	0·016	0·006
Lead	< 0·0001	< 0·0001
Silicon	Trace	Minute trace

Traces: gold, silver, aluminium, calcium, chromium, copper, magnesium, manganese, molybdenum, nickel, titanium, vanadium, tungsten.

Not detected: osmium, arsenic, bismuth, cadmium, cobalt, gallium, germanium, indium, rhenium, antimony, tin, tantalum, thallium.

zoned without further gas evolution. At this stage the zoned region was single crystal, having grown within a few degrees of the [110] direction, and no further zone refining was carried out. The speed of zoning was 0·5 in./min., the final bombarding current and voltage were 100 m.amp. and 0·7 kV., and the operating vacuum approximately 10^{-4} mb. The hardness of the zoned bar was 190 diamond pyramid number and its spectrographic analysis is given in Table 1.

The diameter of the single-crystal bar varied between 0·150 in. and 0·170 in., and it was found that it could be cold swaged without intermediate anneal to wire 0·050 in. diameter, a reduction of approximately 90 per cent in area. Cold reduction of similar bars of this material in the polycrystalline state was possible only to a very limited extent before intercrystalline fracture occurred.

The wire produced from the single-crystal bar, when annealed *in vacuo*, became polycrystalline and could not be subjected to further cold work without intercrystalline fracture. It can therefore be concluded that crystal boundaries do play an important part in the cold-deformation of rhodium, and that the presence of grain-boundary impurities may have a role in this process.

The fact that the analyses of Table 1 may suggest that the concentration of impurities is much lower than is normal to produce grain-boundary embrittlement in face-centred cubic metals is not necessarily evidence that the modes of deformation of rhodium differ essentially from those of other face-centred cubic metals, as the significant impurities may be non-metallic or otherwise not readily determined by the normal methods of analysis. This is an aspect which requires further investigation.

Adsorption and Desorption of Moisture in Fired Ceramic Materials

RECENT communications[1,2] on moisture expansion in fired ceramic materials raise a number of points on which we would like to comment. This phenomenon has been studied in these laboratories for many years, and we summarize below some of the conclusions to which our experimental data have led us.

We do not think moisture expansion can properly be referred to as 'permanent', since under suitable conditions of temperature and pressure it can be reversed. Water can be removed from a steam-expanded material by heating to 110° C., and this desorption is accompanied by a contraction. Heating for a long time at 300° C. usually removes more water, up to about 90 per cent of that adsorbed. Heating at still higher temperatures is accompanied by further gradual loss of water and contraction, and for complete desorption it is necessary to heat to at least 1,000° C. Weight measurements also show that all the water adsorbed during steam-treatment for, say, 20 hr. at 50 lb./sq. in., can be removed by heating to 300° C., and this desorption is accompanied by a complete reversal of the change in size. This suggests that short-term expansion in steam is mainly due to physical adsorption.

Materials desorbed at 1,000° C. adsorb moisture and expand immediately on cooling from this temperature, and continue to do so down to room temperature. This high-temperature adsorption and desorption involve some mechanism other than physical adsorption, and we believe that in addition to the surface activity there is also a penetration process. The practical consequences of these observations are that, unless a standard zero is established, moisture – expansion measurements on treated materials may include an expansion of unknown extent that has occurred during cooling in the kiln. In order, therefore, to obtain strictly comparable values for moisture expansion after leaving the kiln, all pieces should be subject to a preliminary desorption procedure.

In our experience, involving measurements made on some samples for as long as 1,000 hr. in steam at 50 lb./sq. in., and for 3 years at room temperature and atmospheric pressure, we have never found an equilibrium or maximum size to be attained, although the rate of expansion falls off with time. There is evidence that in some cases there is a progressive increase in internal surface area with steam treatment. We believe that a continuous penetration of water into the glassy phase can go on for very long periods of time. It may be, of course, that different considerations apply when steam at higher pressure is used.

In this connexion, we have found that a given weight of water adsorbed at room temperature produces a change in size different from that produced by adsorption of the same weight of water in steam treatment. Moisture expansion results obtained by steam treatment have been shown to be misleading as a guide to moisture expansion at room temperature.

The effect of firing appears to be two-fold. Vitrification produces changes in internal surface area, and over small ranges moisture expansion can be fairly accurately related to surface area. Over wider ranges, changes in the mineralogical composition of the fired material play a dominant part. We have shown that the main crystalline phases in fired ceramic materials have a negligible moisture expansion, and that glassy phases have a high expansion.

Penetration of open glassy structures by water would explain the continuation of moisture expansion over long periods of time, which cannot be explained in terms of surface activity alone. Moulson and Roberts[3] have recently shown experimentally that penetration of water into silica glass does in fact occur in relatively short periods of time within the temperature-range 600–1,200° C. Studies of adsorption of water vapour on silica glass at room temperature by Barrett, Birnie and Cohen[4], show long-term continuous uptake of water, suggesting a kind of diffusion process.

In view of these findings, we do not think that 'rehydration' is a suitable term to apply to the phenomenon of moisture expansion in fired ceramic materials.

A more detailed account of some of this work was presented by A. W. Norris to the Sixth International Ceramic Congress, and will be published in due course[5]. We are indebted to Dr. A. T. Green, director of research, for permission to publish this communication.

CHEMISTRY

Structural Chemistry of Promethium

THE physico-chemical properties of promethium and its compounds are generally predicted from knowledge of the properties of other lanthanides. However, since promethium lies between neodymium and samarium—two elements which show sensible differences in structural behaviour in some of their compounds—an experimental examination of promethium compounds is indicated. This will also throw light on general lanthanide chemistry.

Lanthanide sesquioxides exist in three crystal structures: hexagonal *A*; an ill-defined *B*; and cubic, nearly fluoritic, *C*, the crystal habit depending on the temperature and the atomic number of the lanthanide[1].

Normally, sesquioxides up to and including neodymium exist in form *A*, and those from samarium onwards in form *C*. This behaviour is also reflected in the different capacity of sesquioxides for dissolving, in the solid state, in the fluorite lattice of some dioxides (of cerium, praseodymium, thorium) to give anomalous mixed crystals: sesquioxides up to and including those of neodymium dissolve partially in the fluorite lattice, while those of samarium onwards dissolve in all compositions[2]. Nothing is known regarding the sesquioxide of promethium.

Direct investigations on promethium sesquioxide are not practicable because of the difficulties in obtaining sufficient quantities of the compound. We therefore employed a method using the radioisotope promethium-147, carrier-free.

Measurements of radioactivity were carried out systematically over a large range of temperatures to determine the distribution of promethium sesquioxide between two non-soluble solid phases: one with a fluorite lattice and the other with an *A* structure. These were solid solutions of cerium, praseodymium and thorium dioxides saturated with sesquioxides, and sesquioxides in the *A*-form saturated with dioxides respectively. The two solid phases were separated by dissolving the *A* phase only with suitable solvents.

In all the experiments the promethium sesquioxide accumulated in the cubic phase (*C* form); reversal seemed to occur only at very high temperatures. We therefore infer that over a large range of temperatures promethium sesquioxide has a nearly fluoritic structure.

This type of investigation could also be used to study the changes of structure with temperature in the solid state of dioxides with fluorite-type structures. Details of this work will be published elsewhere.

Tetra-co-ordination of Nickel(II)—Some Complexes with *Cyclo*hexylphosphine

THE problem of the tetra-co-ordination of nickel(II) has recently been the object of much interest[1–3] owing to the peculiar situation of this ion in the field of co-ordination chemistry, and because of the many opportunities for testing theoretical predictions on the structural, magnetic and optical properties of transition metal complexes. Of particular interest are the complexes of the type NiX_22PR_3. These seem to be clear examples of pure tetra-co-ordination around nickel(II). We had previously examined by X-rays the crystal structure of the red diamagnetic compound[4] $NiBr_22PEt_3$, and found it to be trans-planar as expected. We did not detect any co-ordination along the other axis (unpublished work), as occurs in other cases, for example, in nickel *bis*dimethylglyoxime[5].

Issleib *et al.*[6], examining the co-ordinating power of tri*cyclo*hexylphosphine (PCy_3; Cy = *cyclo*hexyl), mentioned the compound $NiBr_22PCy_3$ and described it as an olive-green substance. Since the ligand field around the nickel ion should not be greatly different from that in the analogous complexes containing aliphatic phosphine, this compound was obviously of interest. The green or blue colour has, in fact, been found only among the paramagnetic forms of the nickel–phosphine series[1,7]. Although ligand field theory does not justify any simple relationship between colour and magnetic properties, or structure, many regularities have been observed at one time or another and the relationship is often mentioned as an empirical rule.

It seemed of interest to investigate this class of compounds also, with the aim of collecting more experimental data in order to throw further light on the general problem.

We prepared the following compounds: $NiBr_22PCy_3$, $NiCl_22PCy_3$, $Ni(SCN)_22PCy_3$. Attempts to prepare the nitrate and the perchlorate did not give samples of sufficient purity, although green precipitates, consisting mainly of the phosphine complexes, were obtained. Analyses and characteristics of the compounds are shown in Table 1.

Single crystals of bromide and thiocyanate have been examined by X-rays with the following results: $NiBr_22PCy_3$: triclinic; a, $9{\cdot}98_2$; b, $10{\cdot}2_8$; c, $10{\cdot}7_4$; α, 112° 44′; β, 109° 41′; γ, 90° 41′; z, 1; space group $P\bar{1}$; observed density, 1·34; calculated, 1·37. $Ni(SCN)_2PCy_3$: monoclinic; a, $9{\cdot}63_7$; b, $13{\cdot}3_8$; c, $17{\cdot}8_3$; β, 117° 52′; z, 2; space group, $P2_1/c$; observed density, $1{\cdot}19_7$; calculated, 1·208.

In both cases the nickel atoms lie at centres of symmetry of the crystal, thus showing a trans-planar arrangement of the four ligands.

Table 1. PROPERTIES AND CHARACTERISTICS OF $NiX_2 2PCy_3$ COMPOUNDS

Compound	$Ni(SCN)_2 2PCy_3$	$NiCl_2 2PCy_3$	$NiBr_2 2PCy_3$
Colour	Orange-yellow	Red	Olive-green
Melting point (deg. C.)	230	227	204
Analysis (per cent, calculated values in brackets) C	61·6 (62·0)	62·6 (62·5)	55·1 (55·5)
H	8·8 (9·0)	9·3 (9·6)	8·6 (8·5)
Ni	7·9 (8·0)	—	7·4 (7·5)
Magnetic moment*	Diamagnetic	Diamagnetic	Diamagnetic
Dipole moment* (in benzene)	~0	~0	1·9

* Magnetic moments were measured on the powdered solids by means of a Sucksmith balance. Dipole moments were measured in benzene solution. The compounds are all monomeric in freezing benzene.

Table 2. FREQUENCIES AND MOLAR EXTINCTION COEFFICIENTS OF THE ABSORPTION MAXIMA OF COMPOUNDS $NiX_2 2PCy_3$

Band		X = SCN	X = Cl	X = Br
I	ν(cm.$^{-1}$)	33,500	36,000	35,700
	ε	15,000	4,000	9,000
II	ν(cm.$^{-1}$)			27,000
	ε	—	—	(< 1,000)
III	ν(cm.$^{-1}$)	26,300	25,600	23,300
	ε	12,500	10,000	6,000
IV	ν(cm.$^{-1}$)	(22,000)	20,000–19,000–18,000	18,000–17,000–16,500
	ε	(~500)	~500	~500
V	ν(cm.$^{-1}$)	11,500	11,700	11,500
	ε	1,500	200	1,500

Absorption spectra in benzene were taken between 40,000 and 10,000 cm.$^{-1}$. In Table 2 frequencies and molar extinction coefficients of the absorption maxima are summarized.

The diamagnetism of the three compounds rules out any simple relationship between magnetic properties and colour in this series. A comparison with the series containing phenylphosphine[1] is of interest. In this series, there is a transition from blue-green paramagnetic forms (X = Br, Cl) to a red diamagnetic one (X = SCN); in the former series diamagnetism is already attained with the bromide. This behaviour can be interpreted, from the point of view of ligand field theory, as an enhancement of the field along the P—P axis in going from the aromatic to the saturated phosphines. When the field along the P—P axis is weak it is necessary to reach a stronger field along the X—X axis (X = SCN) in order to stabilize the singlet in its ground-state. There seems to be some sort of additive effect for the fields along the two symmetry axes. It may well be that for weak fields the steric arrangement of the ligands becomes a distorted tetrahedron (as Venanzi[1] seems to find in the case of the aromatic phosphines).

The X-ray results found for $NiBr_2 2PCy_3$ do not agree with the dipole moment of 1·9 Debyes. It is true that this value (obtained making an allowance of 25 per cent P_E for the atomic polarization) refers to steric arrangement of the molecule in solution, where the situation may be different[2,8] from the solid state; nevertheless, the problem of the dipole moment of this compound requires further investigation.

Our X-ray determinations do not exclude as yet the possibility of a co-ordination along the z-axis as well, but analogy with the ethyl phosphine case seems to rule out such a possibility except perhaps for the SCN^- compound, where the nitrogen atom also has co-ordinating power.

The main features of the absorption spectra have been tentatively interpreted as follows. The band around 35,000 cm.$^{-1}$ is attributed to a charge transfer process involving the P—Ni bond electrons. The bands between 23,000 and 26,000 cm.$^{-1}$ are the same type of charge transfer bands for the Ni—X bonds. The weaker bands in the visible region are the well recognized g—g forbidden transitions between d-levels of the central ion. These bands show evidence of structure (see values for band IV in Table 2) which could arise from the overlapping of different electronic transitions in this region. The bromide band at 27,000 cm.$^{-1}$ is probably also of this type. It is interesting to note that the extinction coefficient of these bands is much higher than is usually found in cases of higher symmetry[9]. We are investigating the details of these spectra from the point of view of ligand field theory.

A full account of this study will be published elsewhere.

Thanks are due to Dr. S. T. Hedgcock and Mr. R. O. Kornelsen of the Physics Department of the University of Ottawa (Ontario) for the magnetism measurements.

Gas Phase Oxidation of Hydrocarbons : Endothermic Nature of the Initial Stage of Reaction

IT is generally agreed that the oxidation of hydrocarbons occurs by steps such as :

$$RH + O_2 \longrightarrow R\cdot + HO_2\cdot + Q' \qquad (1)$$

$$R\cdot + O_2 \begin{cases} \xrightarrow{+M} RO_2\cdot - Q'' & (2) \\[2ex] \longrightarrow R' + HO_2\cdot - Q''' & (3) \end{cases}$$

$$R\cdot,\ RO_2\cdot,\ R' \longrightarrow \text{further reactions finally leading to oxides of carbon and water}$$

The initial stage of oxidation as depicted by (1) is endothermic, while (2) and (3), and also many subsequent reactions, are exothermic. Experimentally, however, no evidence seems to have been furnished which would demonstrate the endothermic nature of the initial stage of hydrocarbon oxidation. What is well known is that the reactions are exothermic : cool flames readily appear in the early stages of oxidation of numerous hydrocarbons, particularly n-alkanes (excepting methane and ethane), and cause a considerable rise in the temperature of the reacting gases.

We have recently studied the pre-flame reactions of a wide variety of hydrocarbons in a flow system in silica reaction chambers of different shapes and sizes. A number of thermocouples measured the temperature of the various parts of the system. Those inside the chamber were prevented from exerting any catalytic effects on the reaction mixture by enclosing them in thin-walled silica sheaths, while others were attached to the outside surface of the chamber and the connecting parts. The onset of the oxidation reactions and their progress were followed by measuring the consumption of oxygen as well as by the appearance of oxides of carbon in the gases leaving the reaction chamber. Oxygen was measured by means of a paramagnetic analyser while the oxides of carbon were measured by means of infra-red instruments.

The fuel and air were allowed to flow, at desired rates, into a pre-mixing section maintained at a temperature a few degrees above the boiling point of the hydrocarbon. The mixture was heated on its way to the reaction chamber held at a uniform temperature inside a furnace. The temperature of the furnace was gradually raised so that the oxidation reactions could be studied from the temperature at which they become detectable to the point at which ignition occurs. Until the instant of commencement of any trace of reaction, the temperature of the fuel/air mixture inside the chamber was the same as that of the surface of the chamber. However, as soon as there was the first sign of consumption of oxygen, the temperature of the reacting mixture began to drop below the temperature of the chamber surface. In the case of a stoichiometric *n*-heptane/air mixture with a residence time of 0·9 sec. in a reaction chamber with surface to volume ratio of about 3·3 cm.$^{-1}$, a drop in temperature of 4–5 deg. C. was observed. The drop at the commencement of the reaction increased when concentration of fuel was increased. At a few degrees higher reaction-chamber temperature, when the oxides of carbon began to be formed in appreciable amounts, the temperature of the reacting gases rose above the chamber surface temperature. It increased most markedly with the appearance of cool flames. At temperatures above the cool flame region, in the zone of negative temperature coefficient, the temperature of the reacting gases gradually fell to the level of the temperature of the chamber surface. Thereafter the temperature of the reacting gases and the reaction-chamber surface stayed close to each other until very near the temperature at which normal ignition occurred.

Similar behaviour with regard to the temperature difference in the reaction mixture and that of the chamber surface has been observed in the case of a number of hydrocarbons and related substances. Detailed results on these will be presented elsewhere.

An interesting point regarding the present observations on the drop in temperature of a reacting fuel/air mixture in the initial stages of reaction is its possible relationship to the drop in pressure observed during the induction period of oxidation in closed chambers. Such an observation was first made in the oxidation of methane by Minkoff and Salooja[1]. It was then thought that the drop in pressure might have been due to the formation of methyl peroxide which would involve an overall diminution in the number of molecules. However, no methyl peroxide was detected in the products of reaction during the induction period. It seems possible that the observed drop in pressure of the reaction mixture might have been caused by the endothermic initial stage of reaction.

A Rapid Method for determining the Concentration of Ammonium Sulphate Solutions

The separation of proteins and enzymes by the ammonium sulphate gradient elution technique has been reported by a number of workers[1–4]. Dixon[5] and Kunitz[6] have published a useful nomogram and equation, respectively, for use in the preparation of ammonium sulphate solutions. While the concentration of ammonium sulphate in a solution can be determined by the usual methods (that is, by distillation and titration, by specific-gravity determinations, nesslerization, or by gravimetric methods) they are all time-consuming, often involve large dilutions of the sample and, in general, are not useful for the routine analysis of a large number of samples. The use of refractometry has been investigated in the search for a more rapid method of measuring the concentration of ammonium sulphate in the fractions collected by the gradient elution technique as well as in the classical precipitation method.

Table 1. Refractive Index of Ammonium Sulphate Solutions

Molarity	Temperature				
	30·60°	24·90°	20·50°	13·25°	0·10°
Water	1·3316	1·3321	1·3327	1·3332	1·3338
0·4138	1·3401	1·3410	1·3414	1·3420	1·3430
0·9658	1·3508	1·3514	1·3518	1·3526	1·3539
1·5118	1·3602	1·3610	1·3617	1·3625	1·3640
2·0837	1·3698	1·3703	1·3708	1·3715	1·3730
2·5900	1·3774	1·3781	1·3784	1·3791	1·3808
2·9152	1·3821	1·3830	1·3834	1·3839	1·3855
3·6265	1·3919	1·3922	1·3924	1·3932	1·3949
4·0645	1·3970	1·3975	1·3979 saturated	saturated	saturated

The results of this investigation are shown in Table 1. Ammonium sulphate, when added to water, was found to produce a large increase in the refractive index. However, the increase in the refractive index is not directly proportional to the concentration of ammonium sulphate but, as one might expect, is dependent upon the density of the solution also. This relationship can be adequately expressed by the following equation:

$$y = ad(RI_1 - RI_2) \text{ (temp. const.)} \qquad (1)$$

where y is the molarity of the ammonium sulphate solution, a is a constant, d is the density of the solution and RI_1 and RI_2 are the refractive indices of the solution and water respectively.

The concentration of the solution can also be calculated by the following equation:

$$y = 0{\cdot}0403 + 41{\cdot}1\,(RI_1 - RI_2) + 309\,(RI_1 - RI_2)^2 \qquad (2)$$

where y, RI_1 and RI_2 have the same meaning as in equation 1. Equation 2, calculated by the least-squares method from the data of Table 1, eliminates the need for knowing the density of the solution.

It is not necessary to control, or even to know, the temperature during the measurements as the change in refractive index per degree change in temperature is 0·0001 for both water and ammonium sulphate solutions. The only requirement is that the refractive index of the solution and of the water be measured at the same temperature. The presence of protein in the usual concentrations will not appreciably alter the results. For example, 1·0 per cent crystalline egg albumin was found to increase the refractive index of water by 0·0017. This is in agreement with the value of 0·0018 reported by Kirk[7].

The concentration of an unknown ammonium sulphate solution (0·50–4·06 *M*) can be rapidly determined by the above method with an overall accuracy of ± 1·0 per cent. (The accuracy is much better at the higher concentrations.) While the sensitivity of the method can be increased approximately ten-fold by the use of a dipping refractometer, the Abbe refractometer should prove adequate for determining the usual concentrations of ammonium sulphate employed in gradient elution and the precipitation of proteins.

It is to be emphasized that this method can, and often has, been applied to the determination of the amount of material in various kinds of solutions. Only the particular application of the method reported here is claimed to be original.

Adaptation of a Photometer for the Direct Recording of Column Chromatograms

THE direct recording of chromatograms presents several advantages: it saves time and labour and eliminates all errors inherent in a fraction collector. To actuate the recorder, a suitable method of detecting the eluting bands must be used. Out of several possibilities, absorption of light, especially ultra-violet light, seems the most generally useful, since many laboratories are equipped with a photometer. Although such devices are already mentioned in the literature[1,2], a detailed description seems to be lacking. The only drawback of such a method lies in the rather short expectancy of life of the hydrogen lamp used as source of ultra-violet light. This limits the application of the direct photometric recording method to chromatography of short duration (a few hours). Only the most difficult separations need, however, days or weeks, and most column elution methods can be speeded up by adequate pressure without excessive diminution in efficiency.

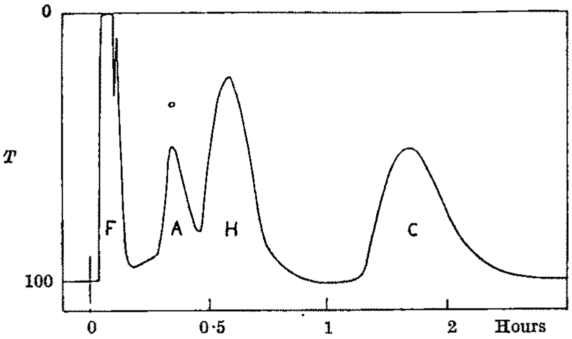

Fig. 1. Chromatography of 2 mgm. hop *a*-acid (California, 1958) (ref. 3). Bands in order of appearance: *F*, front; *A*, adhumulone; *H*, humulone; *C*, cohumulone. Column: 55 cm. × 0·9 cm. Stationary phase: silica gel (ref. 4), grain size 0·15–0·30, phosphate buffer *p*H 9·5 + 10 per cent methanol. Eluted with *iso*-octane which has been freed from oxygen by blowing through nitrogen. Pressure: 2·5 m. water. Flow-rate, 180 ml./hr. This speed can only be obtained when dust-free silica gel is used. Recorder speed, 2 in./hr. Wave-length, 276 mμ

Such a photometric direct recording device for column chromatograms was set up in our laboratory and Fig. 1 shows a typical result of a chromatography terminated in less than 2 hr., which would have taken much longer using the earlier methods (fraction collector—measuring each fraction—plotting the result and calculating).

The only difficulty lies in obtaining a straight and horizontal base-line, which is the same as saying that stability of the photometer in time is required. Providing a 'Beckman *DU*' spectrophotometer with a 5800 ERA energy-recording adapter and recording the energy output with a slow-speed recorder (we use a 'Varian *G*10' graphic recorder with chart roll speeds of 2 and 4 in. per hr.) a slanting base-line is obtained through voltage drop on the accumulator. Adding a Beckman battery power regulator No. 1900, a base-line slanting in the other direction is obtained, even with the lowest charge density. A straight base-line is then obtained by drawing off the battery a current of about 80 m.amp. The actual current intensity is regulated according to the base-line obtained on the recorder.

With a mains-fed Beckman power supply unit no difficulty was met in obtaining a stable and straight base-line, even for 12 hr. on end.

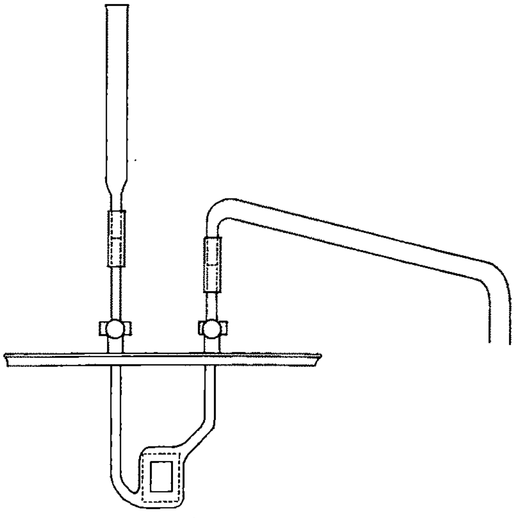

Fig. 2. Flow-cell

The column eluate flows through a special cell which must be as small as possible to prevent mixing. Out of several possible designs that shown in Fig. 2 is most satisfactory. It is made of ordinary glass; two openings are cut out and quartz windows are glued on. Such a flow-cell has a capacity of 2–3 ml. It is mounted in a specially made photobox-lid as shown. The joints are in plastic, although some of this material dissolves in organic solvents to give light absorption. The soluble components are soon all extracted, however, and no difficulties are noted afterwards. The chromatography of Fig. 1 was carried out on 2 mgm. of the mixture; but larger quantities can also be dealt with; it suffices to set the photometer at a wave-length where the specific extinction of the substances is lower. Since the recording is made with the co-ordinates time against transmission, quantitative results are difficult to obtain from it, and more so since the rate of flow of the columns can scarcely be expected to be rigorously constant. With the recording as a guide it is, however, easy to collect each substance separately and then to determine by some analytical method its amount.

To protect the photometer against accidents, the column is not mounted directly over the flow-cell, but about 30 cm. away from the photocell box. The eluate is then run in the flow cell through a small-bore connecting tube. Light penetrates normally in the photocell box through the glass arm of the flow-cell. This must be prevented with a piece of black cloth or paper.

BIOCHEMISTRY and PHYSIOLOGY

Electrophoretic Heterogeneity of Trypsin

The sedimentation behaviour of trypsin near *p*H 3 has been found to be characteristic of a monodisperse solute[1–3]. Bier and Nord[3] have also demonstrated that trypsin, between *p*H 4·0 and 5·0, behaves, in the absence of calcium ions, as an electrophoretically homogeneous protein. However, electrophoresis in the presence of a stabilizing concentration of calcium presents two clearly separated boundaries.

It is well known, however, that the instability of trypsin above *p*H 3 frequently complicates sedimentation and electrophoretic studies of this enzyme. As no study of the electrophoretic behaviour of trypsin near *p*H 2·3 (its point of maximum stability[4]) is available, such an investigation was carried out using paper electrophoresis and buffers of *p*H between 2·6 and 3. A subsequent paper will deal with the behaviour of trypsin at *p*H 2·5 in free boundary electrophoresis.

The electrophoreses were performed in a Durrum-type cell[5], using a potential of 2·5 V./cm., and the experiment was allowed to run for 20 hr. at room temperature (± 25° C.). The buffer used was a mixture of formic acid, pyridine and water in the following proportions: 4·5 : 1 : 94·5. The *p*H of this mixture is 2·6; the addition of 0·03 mole of calcium acetate raises this value to *p*H 2·8.

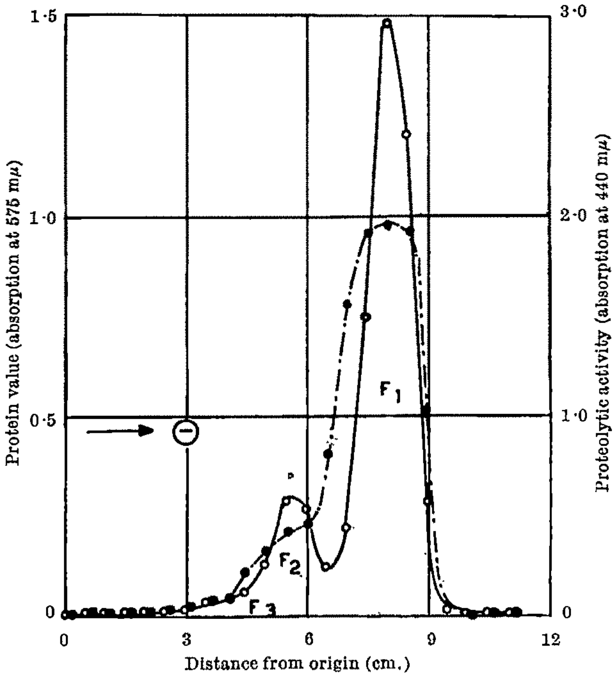

Fig. 1

The trypsin used was a sample of Worthington, twice crystallized, salt-free, batch *TR629SF*, which was found to be homogeneous by free boundary electrophoresis at *p*H 5 in the absence of calcium.

Samples of 0·08 ml. of 4 per cent trypsin dissolved in the same buffer were applied to a 8 cm. × 54 cm. strip of Whatmann No. 3 paper. Immediately after electrophoresis the strip was removed and while still wet, cut longitudinally in such a way to give three segments: two lateral ones, each 2·5 cm. wide, and a central one of 3 cm. width.

The central strip (3 cm. wide) was cut at 0·5-cm. intervals and each paper segment was transferred to a test-tube containing 3 ml. of azo-casein solution for the measurement of proteolytic activity by the method of Charney and Tomarelli[6].

Both lateral strips (2·5 cm. wide) were dried and the proteins dyed by Durrum's method[5]. Some strips were treated with a 0·2 per cent solution of ninhydrin in acetone, containing 5 per cent of pyridine.

The results of our experiments demonstrated that electrophoresis in the conditions used in this work shows the presence in crystallized trypsin of three different fractions, even in the absence of calcium (Fig. 1). When each of these fractions is extracted individually from the paper, lyophilized and again submitted to paper electrophoresis, no further heterogeneity was observed.

Of these three fractions the faster one (F_1) constitutes about 82 per cent of the total protein and accounts for 82 per cent of the proteolytic activity, as measured by the areas under the curves (protein curve and activity curve respectively). The two remaining fractions account for approximately 15 per cent (F_2) and 3 per cent (F_1) of the total proteins, the smaller fraction being also the slower one. The area under the activity curve of fractions F_2 and F_3, taken together, is about 18 per cent of the total. The proteolytic activity of the slower fraction, due to

Table 1

Ca^{2+} *M*	Protein (per cent)		
	F_1	F_2	F_3
0·0	82·7	14·7	2·6
0·025	82·5	14·8	2·7
0·030	83·1	14·2	2·6
0·050	82·5	15·2	2·3

Table 2

Ca^{2+} *M*	Percentage of total area under activity curve	
	F_1	$F_2 + F_3$
0·0	82·0	18·0
0·025	82·7	17·3
0·030	82·2	17·8

its low relative concentration, was not measured separately.

In our experiments, calcium ions up to 0·05 *M* had no influence on the quantitative distribution of the trypsin fractions (Table 1), or on the distribution of activity (Table 2). In both cases, that is, in the presence, as well as in the absence, of calcium, the only ninhydrin-reacting substances observed were the same three fractions mentioned before. The absence of trypsin-split products seems to indicate that no autolysis occurred during electrophoresis.

The identity of F_2 with the fraction which appears during free boundary electrophoresis at *p*H 5 in the presence of stabilizing concentrations of calcium ions is under investigation. A comparison of the proteolytic activity of F_1 with F_2 is also being made.

Albumin labelled with Iodine-131 in an Analbuminæmic Subject

THE behaviour of plasma proteins labelled with iodine-131 in the circulation of animals has been shown[1-3] to correspond with that of the same proteins biosynthetically labelled with carbon-14, supporting the view that the iodine label, if properly applied, may be a reliable indicator of the behaviour of unlabelled molecules.

A unique opportunity to test this directly was presented to us by the availability of a brother and sister with congenital absence of albumin in the plasma[4]. The sister was infused over 9 hr. with a mixture of 148 gm. re-crystallized human albumin (Behringwerke, Marburg) and 3·0 mgm. of the same albumin labelled with 0·80 atom iodine per mole according to procedures which have been described[5,6]. 10 min. after the end of the infusion the plasma of this subject contained 2·63 gm. albumin per 100 ml. and this value only declined to 1·10 gm./100 ml. at the end of 10 weeks, indicating a poor ability to catabolize albumin. During this period numerous measurements were made of plasma radioactivities and of absolute albumin concentrations by (*a*) paper electrophoresis and (*b*) precipitation of total plasma proteins with trichloracetic acid and extraction of albumins with ethyl alcohol[7].

The results (Fig. 1) indicate that specific radioactivities had not changed significantly after 7 weeks and therefore no discrimination had occurred between iodine-labelled and unlabelled albumin molecules.

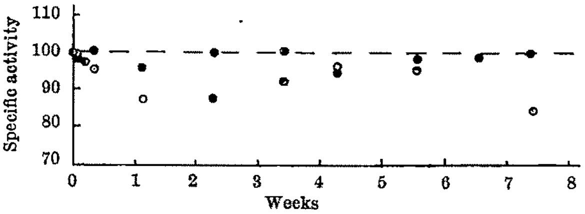

Fig. 1. Specific activities expressed as a percentage of that of the first sample: ⊙, based on electrophoretic estimation of albumin; ●, based on alcohol-trichloracetic acid albumin estimations

A full description is in preparation[8], including details of an earlier experiment on the same patient using a commercial albumin labelled with iodine-131. In this study the labelled albumin, which was injected 3 days before the infusion, was eliminated much faster than the unlabelled albumin.

Effect of Clipping the Coat on the Thermoregulatory Reactions of Dairy Heifers

IT is well known that the coat has a marked insulative value, reducing the ability of the animal to dissipate heat to its environment. The reduction in the loss of heat occurs mainly in the conductive and convective components of loss[1]. The reduction in the potential loss of radiant heat may be of sizeable magnitude when the coat overlying the skin is thick and dense enough to prevent the skin from 'seeing' a cooler environment. There is the further possibility that the coat reduces the loss due to evaporation[2].

This reduction in the loss of heat may be critical in highly productive animals in a hot environment. It may be even more critical in such animals as dairy cattle, which are characterized by a relatively limited ability to dissipate heat by vaporization.

Table 1

	Rectal temperature (° F.)	Resp./min.	Surface temperature (° F.)	Total vaporization (gm./hr./cow)†	Ventilation-rate (l./min.)	Tidal air (l.)	Pulmonary vaporization (gm./hr./cow)	Feed consumed (lb./day)*	Water consumed (gal./day)*	Heat produced (cal./hr./m.²)
Before clipping	103·0	95·1	95·49	739·1	151·0	2·30	150·5	11·88	10·23	549
After clipping	102·9	91·1	95·95	732·3	146·0	2·34	142·2	13·64	10·35	623
Statistical significance of change	—	—	$P < 0 \cdot 01$	—	—	—	—	$P < 0 \cdot 05$	—	$P < 0 \cdot 05$

* Values for consumption of food and water from unpublished data of Ragsdale *et al.* (1958).

† Total values for vaporization from unpublished data of Yeck (1958).

An attempt has been made to evaluate the effect on some thermoregulative reactions by clipping the coat of dairy heifers. Four heifers (2 Brown Swiss and 2 Holstein), 20 months old, previously exposed for one month at high temperatures, were kept for two weeks in air at constant temperature and relative humidity in one of the climatic chambers at the University of Missouri Psychroenergetic Laboratory. The average of readings taken at 2-hr. intervals was 89·1 ± 1·39° F. for the air temperature and 69·0 ± 5·6 per cent relative humidity. These environmental conditions were chosen as they cause a definite thermal stress, but are not too severe.

After one week of exposure the animals were clipped with a hair clipper used regularly in clipping dairy cows. This type of clipper was preferred in order to simulate practices and conditions generally encountered in the dairy industry.

The reactions studied included daily measurements of rectal temperature, respiration-rate, ventilation-rate, tidal air, respiratory vaporization, heat production by the open circuit method[3], water and feed consumption. The surface radiant temperature was measured (using a Hardy dermal radiometer) on five regions of the body, once on the unclipped animals and once after clipping. Total vaporization measurements by the tent method[4] were made twice before clipping and twice afterwards. A fixed schedule of management and timing of measurements was observed.

The averages for the reactions measured are given in Table 1.

The rectal temperature remained practically the same in spite of the clipping. There were drops in respiration-rate, total vaporization, ventilation-rate, pulmonary vaporization, and a similarly non-significant increase in tidal air volume. Although statistically non-significant, the occurrence of all these changes may indicate some alleviation of the thermal stress.

The surface temperature increased by 0·46 deg. F. after clipping, an increase that was highly significant statistically. The loss of heat varies with the temperature gradient between the surface and air temperatures. The increase in the temperature gradient may be estimated by the ratio:

$$\frac{\text{surface temp. after clipping} - \text{air temp.}}{\text{surface temp. before clipping} - \text{air temp.}} = \frac{95 \cdot 95 - 89 \cdot 1}{95 \cdot 49 - 89 \cdot 1} = 1 \cdot 072$$

Therefore, an approximate increase of about 7 per cent may be assumed to have occurred in the temperature gradient, and probably the coefficient of insulation decreased too.

It is noteworthy that this increase in loss of heat was not reflected in a drop in the rectal temperature, although the rectal temperature is a fairly accurate estimate of the deep-body temperature[5].

The animals reacted to the increase in dissipation of heat by increasing their production of heat and consumption of food by a statistically significant amount.

It is generally accepted that the production of heat is closely related to the level of productivity.

The rectal temperature of 103° F., although markedly higher than that accepted as normal, did not inhibit an increase in the production of heat when the loss of heat was accelerated. This indicates the equality of production and loss of heat, as well as the independence of rectal temperature and heat production within the physiological limits of this experiment. On the other hand, this experiment indicates that the peripheral insulation may well have an important place in determining the expression of the full potential heat production of fur-bearing homœothermic animals.

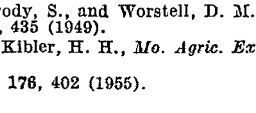
Pharmacological and Toxicological Properties of 5-Benzylidenerhodanine

In connexion with the study of the chemistry of 5-benzylidenerhodanine (5-benzylidene-2-thiooxo-4-oxothiazolidines) by A. Mustafa *et al.*[1] the pharmacological action of these compounds exemplified by 5-benzylidenerhodanine (I) has now been investigated.



(I)

5-Benzylidenerhodanine (mol. wt. 221; m.p. 204° C.) is a yellow, crystalline, odourless substance. It is soluble in aqueous sodium bicarbonate solution, but when warmed with dilute aqueous alkali the heterocyclic ring is opened with the formation of phenylthiopyruvic acid[2–4]. It is soluble on warming with propylene glycol, and its solution is stable to light and air.

Concerning the pharmacological activity it seems, so far as we are aware, that the biological actions of 5-benzylidenerhodanine have not been investigated, except for the observations of Mazzanti[5] on its action on the functional activity of the pancreas. Mazzanti found that it does not affect the level of the blood sugar in rabbits in a dose of 190 mgm./kgm. body-weight for two days.

In these studies the compound was dissolved in 5 per cent sodium bicarbonate solution. The solubility is accelerated by mild heating, a clear yellow solution being obtained. 1 gm. dissolves in about 200 ml. of 5 per cent sodium bicarbonate solution.

Blood-pressure studies were conducted on 5 dogs under ether anæsthesia, and on 3 dogs under chloralose anæsthesia. Carotid blood pressures were recorded with a mercury manometer. Injections were made into the saphenous vein. In a dose of 133 mgm./kgm. body-weight, a rise of blood pressure of about 40 mm. of mercury was recorded. This hypertensive action was of short duration (5 min.). An injection of an equal volume of the solvent alone (5 per cent sodium bicarbonate) produced a rise in blood pressure of about 10 mm. of mercury, After blocking the autonomic ganglia with pentamethonium, the compound still exerted its effect on pressure. It was noticed that after ganglionic blockade the pressor activity was much intensified; but the duration of action remained the same. After the administration of phentolamine, the same dose of 5-benzylidenerhodanine produced an elevation of blood pressure of about 30 mm. of mercury.

The rate and amplitude of respiration were increased during the vascular actions of the drug.

In two of the dogs used in the foregoing studies, electrocardiogram leads I, II and III were taken under anæsthesia and shortly after the injections of 5-benzylidenerhodanine. There appeared to be no significant difference in the regularity or form of the tracing in any animal in any lead.

A very dilute solution of 5-benzylidenerhodanine was prepared (1 in 1,000) and perfused through a toad's heart *in situ*. Ten experiments were carried out. There appeared to be reduction in both the rate and force of contraction, The heart recovered after washing. When the heart was nicotinized with 1 per cent nicotine solution to block the parasympathetic ganglia located in the heart, the drug still produced a cardiac inhibitory action.

A rabbit's heart was extirpated after killing the animal by cerebral contusion. The defibrinated blood was mixed with Locke–Ringer's solution and perfused through the aorta. Tracings were made of the heart-beat. At intervals of 5 min., 5 ml. of 1 in 1,000 solution of 5-benzylidenerhodanine in Locke–Ringer's solution were introduced into the perfusion fluid. Five experiments were made, and in each case the effect upon the rabbit's heart coincided with the results obtained on the toad's heart *in situ*, namely, there is depression of both rate and force of cardiac contractions.

The effect of 5-benzylidenerhodanine on isolated strips of rabbit jejunum was determined. The strips were suspended in oxygenated Locke's solution at a constant temperature of 37° C. At a concentration of 1 in 2,000, 5-benzylidenerhodanine produced a contraction of the normal jejunum which is followed by depression, from which the intestine could be recovered by washing. If nicotine was added to the bath (1 per cent) to paralyse the parasympathetic ganglia and then 5-benzylidenerhodanine added, there was also an initial stimulation of brief duration which was followed by depression. Isolated strips were obtained from virgin rats. They were suspended in oxygenated Locke's solution and kept at a constant temperature of 37° C. In a concentration of 1 in 2,000, 5-benzylidenerhodanine produced a decrease in the uterine tonus with a diminution of the individual contractions. After the uterine strips were first treated with ergatoxine, 5-benzylidenerhodanine still produced a depression in tonus.

The pharmacological activity of 5-benzylidenerhodanine and of 4-benzylidene-2-thiooxo-5-oxothiazolidine will be described elsewhere.

The γ-Aminobutyric Acid and Glutamic Acid Content of Brains of Rats treated with Toxopyrimidine

In 1939, Abderhalden[1] found that the administration of the pyrimidinic moiety of the thiamine molecule (2-methyl, 4-amino, 5-oxymethylpyrimidine; toxopyrimidine) to rats reared on suitable diet caused convulsions and death in a few hours. Afterwards, Makino *et al.*[2,3] showed that the convulsive action of the toxopyrimidine could be overcome by administering pyridoxamine, and Makino and Koike[4,5] gave enzymatic evidence of the competitive antagonism between vitamin B_6 and toxopyrimidine showing the *in vitro* inhibition of tyrosine-decarboxylase by toxopyrimidine phosphate.

The role of pyridoxine deficiency or antagonists in the seizure mechanisms has been well established[6,7]. Tower[8] emphasized the importance of the glutamic–γ-aminobutyric acid system in neuronal activity and the close connexion between the dysfunction of this system and the onset of convulsions.

Since toxopyrimidine, which *in vitro* has an anti-pyridoxine action, produces *in vivo* epileptic seizures, it seemed desirable to study the *in vivo* action of this substance on the glutamic-γ-aminobutyric system of the brain, in relation to the activity of glutamic-decarboxylase.

Therefore, we determined the γ-aminobutyric acid and glutamic acid contents of the brain of rats treated both with toxopyrimidine and toxopyrimidine followed by pyridoxamine.

Male albino rats, weighing 60–70 gm., placed for 7 days on a diet deficient in vitamin B_6 similar to that described by Makino *et al.*[2], were intraperitoneally injected with toxopyrimidine (125 μgm./gm. body-weight), dissolved in saline. At 90–120 min. after the injection, that is, after the onset and several replications of the convulsive seizures, the animals were killed by decapitation. The pyridoxamine (62 μgm./gm. body-weight) was injected in the peritoneum of rats showing seizures, and the animals were killed at different times after the

Table 1. γ-AMINOBUTYRIC ACID AND GLUTAMIC ACID CONTENT OF THE BRAIN OF RATS TREATED WITH TOXOPYRIMIDINE

Table 2. γ-AMINOBUTYRIC ACID AND GLUTAMIC ACID CONTENT OF THE BRAIN OF RATS TREATED WITH TOXOPYRIMIDINE AND PYRIDOXAMINE

No. of experiments	Condition	Hours after vitamin B_6 injection	Content (mgm./gm.)	
			γ-Amino butyric acid	Glutamic acid
11	Treated	0	$0{\cdot}161 \pm 0{\cdot}007$	$1{\cdot}59 \pm 0{\cdot}059$
8	Treated + B_6	1½	$0{\cdot}175 \pm 0{\cdot}005$	$1{\cdot}49 \pm 0{\cdot}074$
4	Treated + B_6	3½	$0{\cdot}203 \pm 0{\cdot}012$	$1{\cdot}56 \pm 0{\cdot}005$
4	Treated + B_6	6	$0{\cdot}199 \pm 0{\cdot}015$	$1{\cdot}47 \pm 0{\cdot}170$
12	Normals	0	$0{\cdot}203 \pm 0{\cdot}003$	$1{\cdot}53 \pm 0{\cdot}028$

injection (Table 2), when all convulsive symptoms had disappeared.

The controls received the deficient diet for 7 days, and the normal rats were kept on the complete diet used by us in breeding. In every case, after decapitation, the brain was removed very quickly, weighed and homogenized in 75 per cent ethanol in centrifuge tubes.

The γ-aminobutyric acid and glutamic acid were extracted from the brain following the method of Roberts and Frankel[9] with slight modifications.

The extract was applied on a wide sheet of Whatman No. 1 filter paper using an 'Agla' micrometer syringe. Four controls were run in each chromatogram. The developing solvent for the descending chromatography was a freshly prepared solution containing *iso*propanol/acetic acid/water (100 : 24 : 20)[10]. Chromatography continued for 40–44 hr. at $20 \pm 2°$ C. The spots were revealed and eluted following the method of Montreuil and Khouvine[11]. The optical densities were read in a Beckman spectrophotometer model *DU*, at 505 mμ, using 1-cm. cuvettes.

The results summarized in Table 1 show that, while the 7 days of vitamin B_6 deficiency failed to modify the γ-aminobutyric acid cerebral content, toxopyrimidine, which produced serious epileptic seizures, caused a statistically significant ($t = 6{\cdot}38$; $P < 0{\cdot}001$) decrease of this amino-acid in comparison with the controls. No detectable modification, on the contrary, was found in the glutamic acid content.

The administration of pyridoxamine to the epileptic rats, which stopped the convulsions in about 1 hr., did not modify the γ-aminobutyric acid cerebral content so quickly. In fact, the normal level in the brain was attained only after 3½ hr. from the vitamin injection, although at 1½ hr. some increase was already noticeable (Table 2).

The decrease of the γ-aminobutyric acid content of the brain, after administration of toxopyrimidine, is likely to be related to the inhibition of the glutamic-decarboxylase by toxopyrimidine. Work on this is now in progress in our laboratory.

It is more difficult to explain the finding of no modification in the glutamic acid content of the brain. Tentatively, we can assume that the amount of this acid derived from the inhibition of the glutamic-decarboxylase was further metabolized to support the energy needs during epileptic seizures[12], so disappearing from the tissue.

Effect of Dietary Protein on the Severity of Experimental Mouse Hepatitis

THERE are few observations concerning the effect of nutritional state on human hepatitis. These have produced conflicting results[1,2]. As all attempts to culture the virus of human infectious hepatitis have been unsuccessful[3] the effect of dietary deficiency on mouse hepatitis was investigated. *M.H.V.*3 virus isolated by Dick, Niven and Gledhill[4] was selected. This virus is uniformly fatal to weanling mice but mortality decreases with age. Swiss Webster strain mice (Budd Mountain Farm, Chester, New Jersey) were used. The severity of *M.H.V.*3 infection is enhanced by *Eperythrozoon coccoides*. Peripheral blood films from the experimental mice showed they did not carry *Eperythrozoon coccoides*.

It has been shown that choline deficiency does not affect the course of mouse hepatitis virus infection[5]. During this work it was noticed that the mortality of mice on some of the experimental diets was much higher than that of mice on a standard laboratory diet. The standard laboratory diet was 'Purina Chow', which is stated by the manufacturer to contain 26·8 per cent protein. The experimental diets contained considerably less protein.

The effect of two diets differing in protein content was therefore studied. One experimental diet consisted of (per cent by weight):

Casein	26
Dextrin	62·5
Lard	6
Cod liver oil	1
Salt mixture No. 2 U-S-P.	3
Vitamin mixture (ref. 6)	1
Alpha tocopherol	0·01
Choline	0·5

The other diet contained 8 per cent casein and 80·5 per cent of dextrin, but was otherwise identical in composition. Both diets were adequate for growth, but weight gain was more rapid in the animals on the high protein diet.

In one typical experiment two groups of 30 mice, aged 32 days, which had been on the experimental diets for eleven days, were inoculated intraperitoneally with 0·1 ml. of a 1 per cent mouse liver suspension obtained from mice infected with *M.H.V.*3 virus.

Table 1. Number of Mice dying each day after injection of *M.H.V.*3 Virus

	Day 1	2	3	4	5	6	7	8	9	10	11	12	Total deaths
High protein diet: (30 mice)	0	0	0	3	3	3	0	0	0	0	0	0	9
Low protein diet: (30 mice)	0	0	0	5	8	5	1	0	0	0	0	0	19

The number of mice dying each day after injection is shown in Table 1. The mortality rate of mice on the high protein diet was thus approximately half that of mice on the low protein diet. This difference is statistically significant ($\chi^2 = 5 \cdot 6$, $P < 0 \cdot 02$). It is concluded that a decrease in protein content affects adversely the mortality from virus hepatitis in mice. This finding confirms that a high protein diet is protective against hepatotoxic agents[7] and is in keeping with observations suggesting that dietary deficiency may be harmful in human hepatitis[2].

Mirick and Leftwich[8] found that a prolonged deficiency of pyridoxine adversely affected the resistance of mice to pneumonitis virus. In their paper they review a few previous similar observations. One of these was made by MacCallum and Miles[9], who inoculated material from patients with infectious hepatitis into rats. They produced a transmissible disease in protein-deficient rats but not in well-nourished animals. In view of subsequent work on infectious hepatitis it seems likely that in their findings, as in the present investigation, a rodent virus rather than a human virus was causing the experimental hepatitis. While the clinical picture of many virus diseases can be altered by dietary deficiency[10] the usual effect is to render animals on deficient diets relatively insusceptible. The present observations, like those of Mirick and Leftwich[8], constitute an exception to this rule.

Oxidative Metabolism of Cartilage

Although utilization of oxygen by mature cartilage is very low, with Qo_2 values ranging between 0 and 0·68[1–5], studies by Rosenthal, Bowie, and Wagoner[6] and Boyd and Neuman[7] have shown that embryonic cartilage utilizes significantly greater amounts of oxygen (Qo_2, 2·2). Paradoxically, although dehydrogenases customarily mediated via cytochrome oxidase (that is, succinic and isocitric dehydrogenases) have been identified in both mature and embryonic cartilage[1,8], until now the biochemical demonstration of cytochrome oxidase activity in cartilage had not been accomplished.

Table 1. Cytochrome Oxidase in Cartilage Homogenates

(*a*) Oxidation of reduced cytochrome *c* at 550 mμ

Specimen	Mgm. (dry weight) tissue per cuvette	Decrease in absorbance in 3-min. interval
Limulus	0·46	−0·102
Busycon	0·78	−0·185
Squalus	1·10	−0·130

(*b*) Manometric oxidation of hydroquinone in system limiting for cytochrome oxidase

Specimen	Mgm. (dry weight) tissue per Warburg vessel	Observed oxygen uptake (μl./hr.)	Qo_2 (μl./hr./mgm. dry tissue)
Limulus	4·4	44	10·0
Busycon	8·1	76	9·4
Squalus	12·7	95	7·9

In this communication cytochrome oxidase activity in cartilage from invertebrate and vertebrate forms, and the existence in cartilage of substances which inhibit cytochrome oxidase activity are reported.

Since cytochrome oxidase is by definition[9] the enzyme which oxidizes reduced cytochrome *c*, this ability was the first criterion used in demonstration of the enzyme in cartilage.

In Table 1*a* are results from typical experiments demonstrating the oxidation of reduced cytochrome *c* by gill cartilage homogenates from young specimens of *Limulus* (horseshoe crab), *Squalus* (dog-fish), and odontopore cartilage from *Busycon* (whelk). Autooxidizability of cytochrome *c* and settling of homogenates were eliminated in these experiments. Boiled homogenates were inactive. The ability of homogenates to oxidize reduced cytochrome *c* was inhibited 80 and 45 per cent by 10^{-4} *M* cyanide and azide, respectively. These results represent the first spectrophotometric demonstration of the oxidation of reduced cytochrome *c* by cartilage from any source.

In Table 1*b* results are given for the manometric determination of cytochrome oxidase activity[10] using hydroquinone as substrate and added cytochrome *c*. Boiled homogenates were inactive. Without exogenous cytochrome *c* enzymatic hydroquinone oxidation was not demonstrable. 10^{-4} *M* cyanide and azide inhibited 55 and 34 per cent, respectively. The Qo_2 values, ranging between 7·9 and 10·0, are the highest thus far reported for cartilage tissue.

The occurrence of negative and questionable experiments during the above studies led to the conjecture that cartilage homogenates might contain substances which inhibit oxidative metabolism. Preliminary evidence for the existence of such inhibitors was found in the studies of cartilage metabolism by Lutwak-Mann[11]. Accordingly, experiments were performed to test this hypothesis. In Fig. 1 is depicted the effects of addition of *Limulus* gill cartilage upon cytochrome oxidase activity of rat-heart-muscle homogenates. As the quantity of cartilage homogenate added to the system was increased, the oxygen utilization of a given amount of heart homogenate decreased. Similar inhibitory actions were found in cartilage from the whelk, dog-fish, rat, and dog, using both manometric and spectrophotometric assays for cytochrome oxidase activity. Neither cytochrome oxidase activity nor the existence of inhibitory substances have been detected in head cartilage from *Loligo* (squid), which

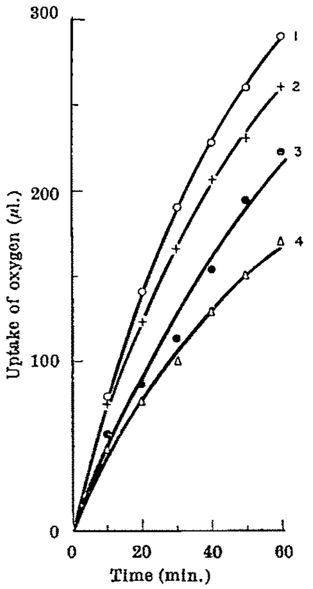

Fig. 1. Effect of adult *Limulus* gill cartilage on hydroquinone oxidation via cytochrome oxidase of rat-heart homogenate. Curve 1, 1·0 ml. rat-heart homogenate in total volume of 3·0 ml. Curves 2, 3 and 4 contain in the same total volume 1·0-ml. rat-heart homogenate, plus 0·1, 0·5 and 1·0 ml., respectively, of cartilage homogenate

has also been studied. Full details of the above experiments are being prepared for publication elsewhere.

Since cartilage cells 'degenerate' as the tissue matures (even in young animals), one reason for the past inability to detect cytochrome oxidase in cartilage may be such cell degeneration. Another reason, now evident and requiring more detailed study and consideration, appears to be the presence in cartilage of inhibitors of oxidative activity.

Chemical Excitation of Spinal Neurones

THE presence of comparatively large quantities of glutamic acid in brain together with the conflicting evidence of the effects of glutamic acid administration[1] have led to an investigation of the effects of this and related monoamino-dicarboxylic acids upon spinal cells. When applied ionophoretically, both glutamic and aspartic acids were very effective in evoking repetitive discharges from all types of interneurones located in the dorsal horn and intermediate nucleus of the spinal cord of the cat. For example, Fig. 1*A* illustrates the spike potentials of a dorsal horn cell activated orthodromically and recorded by means of one barrel of a double-barrelled electrode. The background discharge-rate of this cell was zero (Fig. 1*B*). Several seconds after a current of 120 mμ amp. was employed to pass anion from a saturated solution of the sodium salt of L-glutamic acid (*p*H 8·5) in the other barrel of the electrode, the cell fired with a frequency of 100 per sec. (Fig. 1*C*), and 5 sec. later this had risen to 440 per sec. (Fig. 1*D*). 1 sec. after the current was stopped, the cell ceased firing. Control experiments indicated that this excitatory action was due specifically to the amino-acids and not to other effects arising from the passage of the ionophoretic currents.

When these substances were similarly applied to the surface of motoneurones from the extracellular barrel of a co-axial electrode, the intracellular electrode recorded a membrane depolarization which, when summed with the depolarization arising either from current passed through the intracellular electrode or from sub-threshold synaptic excitation, fired the cell. Intracellularly recorded excitatory and inhibitory post-synaptic potentials of motoneurones were found to be slightly changed by the extracellular ionophoretic application of aspartic and glutamic acids. These effects would be expected to arise as a result of the concurrent depolarization[2].

Renshaw cells, activated in the typical manner by acetylcholine applied ionophoretically from one barrel of a multibarrel electrode, were also excited by glutamic or aspartic acids applied in a similar fashion

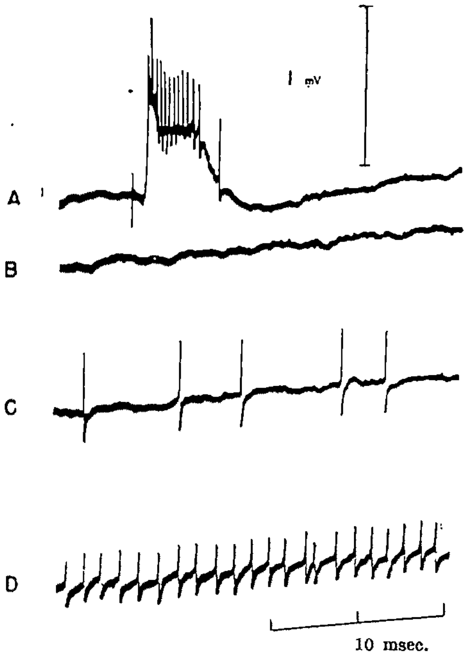

Fig. 1. Spike potentials of an interneurone located in the dorsal horn of the spinal cord and recorded from the sodium chloride containing barrel of a double barrel electrode. *A*, stimulation of the superficial peroneal nerve; *B*, background discharge in the absence of stimulation; *C* and *D*, recorded as in text during the passage of glutamic acid from the other barrel of the electrode into the extracellular environment of the cell. Voltage calibration 1 mV. for all records. Time, 10 msec.

from another barrel. Since neither interneurones nor motoneurones responded to acetylcholine applied ionophoretically, it appears that these amino-acids are capable of exciting neurones normally activated synaptically by different transmitter agents.

Consequently, these observations suggest that glutamic and aspartic acids have a non-specific excitatory action upon certain spinal neurones, a finding which is in accordance with earlier observations upon the non-specific depressant actions of the related monoamino-monocarboxylic acids[4]. These results provide a possible explanation of the convulsive disorders associated with disturbances of glutamic and aspartic acid metabolism[5].

Anti-Tumour Activity of 5-Mercaptouracil

5-MERCAPTOURACIL, a structural analogue of thymine, was synthesized several years ago[1,2]. This compound (and its disulphide) inhibited the growth of *Lactobacillus leichmannii* at 1–3 µgm./ml. concentration, and this inhibition could be reversed 'competitively' with thymine. It was tested in several experimental mouse tumours; in some cases, it caused tumour inhibition of borderline significance, at less than the maximum tolerated dose[3].

The effect of 5-mercaptouracil on the biosynthesis of deoxyribonucleic acid was studied, by microbiological inhibition analysis techniques, in relationship with other antimetabolites[4]; this work was part of a research programme aimed at the inhibition of biosynthesis of deoxyribonucleic acid at several consecutive and/or alternative reaction steps. It was concluded that there are at least two alternative pathways for the biosynthesis of 'DNA-thymine', only one of which (Fig. 1, *a* + *b*) involves the utilization of thymine itself. The ability to convert thymine to thymidine (step *b*) which, at least in the case of *L. leichmannii*, requires either the catalytic action of vitamin B_{12} or the presence of deoxyribosides, varies from organism to organism; it may be expressed in a quantitative manner by a 'conversion ratio'[4], high for *L. leichmannii* (1 : 5) and low for *L. arabinosus* (1 : 450). This conversion ratio is increased by excess thymine ('mass action'), decreased by thymine antagonists, and not directly affected by anti-folic or anti-uracil compounds. Although the latter antimetabolites do inhibit the preceding (*a*) step (that is, the conversion of uracil to thymine), this step is altogether by-passed in the presence of exogenous thymine.

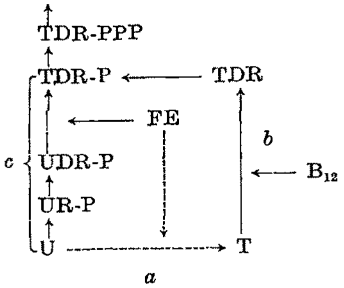

Fig. 1. Pathways of DNA-thymine biosynthesis from uracil and thymine. Abbreviations: U, uracil; UR-P, uridylic acid; UDR-P, deoxyuridylic acid; T, thymine; TDR, thymidine; TDR-P, thymidylic acid; TDR-PPP, thymidine triphosphate; DNA-T, deoxyribonucleic acid-thymine; FE, folic acid (tetrahydrofolic acid) enzyme; B_{12}, a 'vitamin B_{12} enzyme'

The alternative (*c*) pathway requiring the folic acid (tetrahydrofolic acid) enzyme is strongly inhibited by anti-folic and anti-uracil compounds, and is unaffected by thymine or thymine antagonists. Some thymine antagonists, however, may act here as 'substitute metabolites'. 5-Bromouracil, for example, actually reverses the inhibitory action of anti-folic and anti-uracil compounds[4]. More recent work by Friedkin[5] and by Kornberg[6] established the intermediate reaction steps along route *c* of our scheme[4] in the manner indicated in Fig. 1.

On the basis of this more detailed representation of route *c*, it is now possible to understand, by analogy, the corresponding transformations of 5-bromouracil (by the enzymes of route *c* but bypassing the methylation step) which lead to its incorporation into deoxyribonucleic acid.

In contrast, 5-mercaptouracil does not seem to act as a 'substitute metabolite' along route *c*; and, probably by inhibiting the alternative *a* + *b* pathway at step *b*, it seems to potentiate the inhibitory action of anti-folic and anti-uracil compounds. This was found to be the case in various microbiological systems (results will be reported elsewhere); particularly strong synergism was found between 5-mercaptouracil and 2,4-diamino-6,7-dimethyl-2,4-deoxyalloxazine[7] in inhibiting the growth of *L. arabinosus*.

The synthesis of 5-fluorouracil by Heidelberger and his co-workers[8] provided a most effective anti-uracil compound which is far superior to 5-nitrouracil used in our earlier work[4]. The transformations of 5-fluorouracil (along route *c*) to 5-fluorodeoxyuridylic acid, and its mechanism of action via inhibition of the methylation step, have been described[9]. As it blocks the same reaction step of route *c* which requires the folic acid (tetrahydrofolic acid) enzyme, it is not surprising that there is no synergism between 5-fluorouracil and folic acid antagonists[10].

5-Fluorouracil is a powerful inhibitor of several mouse and rat tumours[8]. These animals are known to utilize thymine very poorly[11]; instead, route *c* appears to be their main pathway of deoxyribonucleic acid–thymine biosynthesis. However, if route *c* is blocked by 5-fluorouracil, route *b* becomes important, as indicated by a significant increase in the effectiveness of 5-mercaptouracil as an inhibitor of tumour growth. This effect was demonstrated in several mouse tumours. The results of the sarcoma 180 and adenocarcinoma 755 experiments are summarized in Table 1 (detailed results will be published elsewhere).

The results indicate that 5-mercaptouracil, in the presence of a relatively low dosage-level of 5-fluorouracil, causes significant inhibition of tumour growth. This fact is of potential chemotherapeutical interest

Table 1. Inhibitory Action of Combinations of 5-Fluorouracil (FU) and 5-Mercaptouracil (MU) in Animal Tumours

Tumour	Compound	Dose (s.c.) (mgm./kgm./day)	Mean tumour weight treated/control
Sarcoma 180	FU	10	* 0·61
	MU	5	0·76
	FU MU	10 5	0·22
Adenocarcinoma 755	FU	10	† 0·49
	FU	25	0·47
	MU	5	0·94
	MU	50	0·93
	FU MU	10 5	0·38
	FU MU	10 50	0·38
	FU MU	25 5	0·28

* Mean, calculated from mean treated/control results of four experiments, totalling 35 mice for each treatment.

† Mean treated/control results of one experiment with 10 mice in each group.

because: (1) it offers the possibility of reducing the clinically effective dosage of 5-fluorouracil from its present toxic level[12]; (2) since, on the basis of available although indirect evidence[13,14], the thymine (vitamin B_{12}-catalysed) pathway is more important in humans than in mice, 5-mercaptouracil may be relatively more effective as a therapeutic agent.

We are grateful to Dr. J. A. Aeschlimann and Dr. R. Duschinsky, of Hoffmann-La Roche, Inc., for gift samples of the 5-fluoropyrimidine compounds.

An Equation for the Flow of Blood, Plasma and Serum through Glass Capillaries

WHEN blood flows through narrow tubes, the larger suspended particles tend to accumulate in the centre, leaving a zone of plasma near the walls. In mammals, the red cells are smaller than the leucocytes but, when associated in groups (rouleaux or clumps), they will tend to replace the leucocytes in the centre, thus altering the distribution of concentration. This means that Poiseuille's fourth-power radius law fails to hold[1]. Several authors, notably Fåhraeus[2], have stressed the importance of this in large and small vessels *in vivo*. The significance of intravascular clumping or 'sludging' has been widely discussed by Knisely and his school[3] (see also ref. 4).

A quantitative measure of the changes in apparent viscosity, defined as shear stress (τ) divided by shear rate (D), when this is not independent of D, is not difficult so long as the curves plotting D against τ (known as 'flow curves') are straight, as is the case with soil and most clay pastes. Schofield and Scott Blair[5], who studied these systems, introduced the term 'sigma phenomena' to describe all deviations from the fourth-power radius law, whatever their cause. For blood, no equation would seem yet to have been proposed which gives a satisfactory linear relation by means of which the sigma phenomena for varying capillary radii can be quantitatively expressed.

Copley, Krchma and Whitney[6] came near to finding a solution so long ago as 1942. They pointed out that flow-curves for blood are nearly straight, but give an intercept on extrapolation to the stress or pressure axis, that is, blood approximates to Bingham's well-known equation in which D is proportional to $\tau - \tau_0$ where τ_0 is a yield-value. Since the curves are not quite straight, however, they suggested that "a more exact relationship might be that of Herschel and Bulkley[7] or some similar variation". This implies plotting log $(\tau - \tau_0)$ against log D; but the results have not proved altogether satisfactory.

Recently, Casson[8,9], basing his calculations on certain assumptions concerning the magnitude of inter-particle forces and disruptive stresses in chain-like floccules present in varnishes and printing inks, has derived a very simple equation to replace that of Bingham:

$$\tau^{1/2} = k_0 + k_1 D^{1/2}$$

which reduces to the Newtonian law when $k_0 = 0$.

Steiner[10] has recently shown that this equation holds over a wide range of shear-rates for melted chocolate and that it makes possible a satisfactory comparison of data from very different types of viscometer, for this material.

Mr. F. A. Glover and I have recently made a number of measurements on the viscosity of cows' blood (treated with anticoagulant) and of its plasma and serum in a series of capillary viscometers with diameters ranging from 0·1 to 0·6 mm. and have confirmed the presence of marked sigma phenomena, especially in the narrower tubes, though plasma and serum are occasionally so nearly true fluids that the anomalies are sometimes too small to measure. Dr. A. L. Copley and his staff have also kindly made available to us a large number of similar results on both human and bovine blood. Not many suitable results appear in the literature, but figures from the works of Kümin (cows' blood)[11], Suter (defibrinated

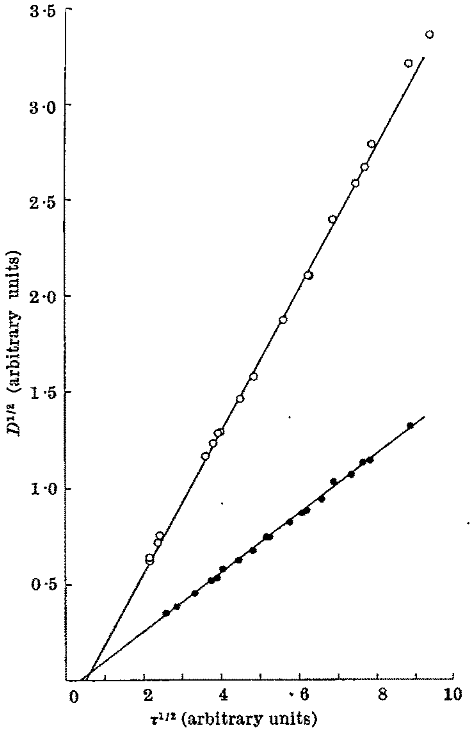

Fig. 1. Two samples of cows' blood, after Kümin

ox blood)[12] and Bircher, cited by Müller (pig's blood)[13], show remarkable linearity when $P^{1/2}$ is plotted against $V^{1/2}$, except perhaps at the highest rates of shear (P, pressure ; V, volume flow/sec.).

A similar linearity was found for all the unpublished results available. It has not always been possible to convert the published data so as to plot τ against D, but this does not affect the straightness of the curves for each individual capillary. By way of illustration, two curves are shown from Kümin (Fig. 1) and one curve from an experiment carried out by Mr. Glover, on human blood supplied by Dr. Copley (Fig. 2). In Fig. 1 a few points, queried by Kümin, are omitted and the units are arbitrary, nor are they comparable for the two samples. In Fig. 2 absolute units are used.

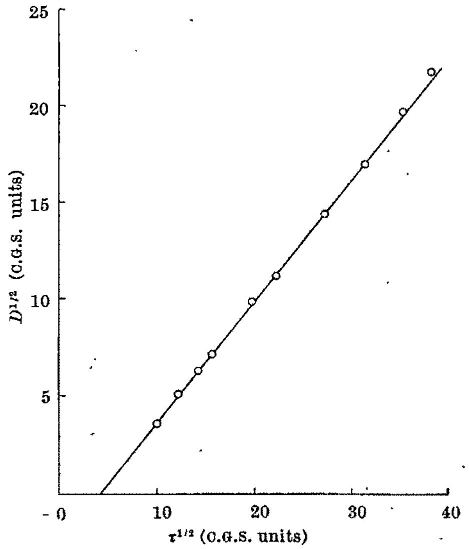

Fig. 2. Healthy human blood

For wide capillaries (diameter > 0·15 mm.) the slopes and intercepts of the $\tau^{1/2}/D^{1/2}$ curves do not differ greatly but, in narrower tubes, marked changes occur, especially in the values of k_0, which may thus be directly related to the radius in order to measure the extent of the sigma-phenomenon.

The results of these experiments will be published in full elsewhere. The purpose of the present communication is to show that a plot of $\tau^{1/2}$ against $D^{1/2}$ for blood, plasma and serum of several species, gives excellent straight lines which extrapolate to the origin only in the special case where deviations from Newtonian behaviour are too small to measure, thus giving a simple quantitative expression for the extent of the very important sigma phenomenon.

I am indebted to my colleague Mr. F. A. Glover, who has done many of the experiments, and to Dr. A. L. Copley, director of experimental research on vascular diseases at Charing Cross Hospital, for his generous supply of data and for many helpful discussions, and to Dr. N. Casson for the loan of a proof copy of his chapter in a forthcoming book.

Effect of a Sympathomimetic Agent (Methoxamine Hydrochloride) on Growth of Hair in the House Mouse (*Mus musculus*)

The association of an intense capillary network with regions of active hair growth in the rat[1] suggests that blood supply plays an important part in the mechanism of the hair cycle in rodents. It was therefore of interest to test the effects of a vasoconstrictor sympathomimetic drug, methoxamine hydrochloride (β-hydroxy-β(2,5-dimethoxyphenyl) *iso*propylamine) on the time taken for the spread of the hair wave and on the amount of hair grown during the cycle.

The offspring of $CBA \times A^w$ females backcrossed to A^w males were weaned and the dorsal hair clipped at 21 days of age. A small patch on the head was also clipped. These mice were then weighed daily, and the areas of new growth, as shown by the appearance of yellow hair tips, were noted. The back was divided into six regions for the spread of the hair wave and the date recorded when hair appeared. The regions in order of appearance of hair were shoulder, mid-side, flank, anterior dorsal, mid-dorsal

and posterior dorsal. The majority of mice followed this cycle, which is described by Borum[2] as type III. The mice were shaved again about 12 days after growth commenced in the final stage and the weight of hair grown during the second cycle on the back was thus obtained. The initial stages of the third cycle rarely started before a further 12 days.

Methoxamine injections were given daily from weaning until the shaving at the end of the cycle or, if later, when hair appeared on the head. Constant doses were given subcutaneously throughout. Dose-rates of 0·15 and 0·25 mgm. in 0·05 ml. were used with both males and females and additional males were given 0·35 mgm. daily. Control animals were injected with 0·05 ml. of physiological saline.

The results shown in Table 1 were those from all treated animals of each sex grouped together because differences attributable to the different dose-rates could not be detected. The duration of the hair wave was taken as the time from the first appearance of new hairs to the appearance of hairs in the final area on the back.

The treatment decreased the weight of hair grown by mice of both sexes and also increased the duration of the hair wave of the females. A retarding of the stage of the hair wave at 30 days of age may also have occurred for the males. The greater sensitivity of the females appears to be associated with the longer duration of their wave and also their slower body growth, but further results are required to confirm these relationships. However, the male animals showed a significant positive regression within the treatments ($P < 0·01$) between body-weight and the stage of cycle at 30 days and between this body-weight and hair-weight ($P < 0·001$). Analyses of covariance using these regressions did not alter the significance of the difference shown for males in Table 1. This suggested that the methoxamine was not acting through effects on growth of the body. The age at which hair growth appeared on the head was not analysed as four of the treated females and one treated and one control male had shown no growth in this position by the end of the experiment. Of those treated animals showing growth in this position, five shed the new growth on the previously clipped area, while seven shed the first-cycle hairs on the head and face as well. This shedding of first- and second-cycle hairs occurred in a definite symmetrical pattern which extended from a line between the ears to a point between the eyes and in some cases extended down the side of the nose. This pattern shedding on the head could also be induced by one 0·35 mgm. dose of methoxamine at the time of commencement of hair growth on the head. Some slight shedding also occurred in a few treated mice on various parts of the body but more detailed studies are required to determine to what extent the reduction in hair-weight is the result of such slight shedding and whether it occurs in those mice where thinning of the coat was not observed.

These preliminary experiments indicate that the control of blood supply can be of considerable importance to the progress of the hair wave and the growth of hair in these mice. The greater sensitivity of the hair follicles of the face and head would suggest that blood supply is more critical in this region. This is probably associated with a lesser supply than other regions during the resting phase of the cycle. The pattern of shedding in the head region was very similar to the pattern of dark fur on the head of the Siamese cat, in which the darker fur is associated with a lower skin temperature and presumably lesser blood supply.

Further experiments are being carried out with vasodilator substances, and, in addition, the various relationships between body growth, the hair wave and the weight of hair grown are being examined for larger numbers of mice. The investigations will be confined to the second hair-cycle, as later cycles have overlapping hair waves, thus making it difficult to obtain the weight of hair grown in one cycle only.

I should like to acknowledge the assistance of Burroughs Wellcome (N.Z.), Ltd., and the Wellcome Foundation in supplying 'Vasoxine' brand methoxamine hydrochloride. The mice are maintained with the assistance of a grant from the New Zealand Department of Scientific and Industrial Research.

Glycosidases in Some Farm Animals

IT has been shown that the rat epididymis is the richest known source of α-mannosidase, β-galactosidase and β-*N*-acetylglucosaminidase[1], whereas the female rat preputial gland is the richest source of β-glucuronidase[2,3]. The possibility that the corresponding tissues in large farm animals might be convenient sources of these enzymes was considered. Unfortunately, the ewe, cow and sow lack any gland resembling the female rat preputial gland. The distribution of the four simple glycosidases in ram, bull and boar epididymis is shown in Table 1. For pur-

Hyaluronidase	1,400	5,100	550	320	250	890	—	—

* Quoted from Conchie *et al.* (ref. 1).

poses of comparison, the activities in testis were determined, and earlier rat figures are also quoted. The same assay methods as before were employed[1]. Because of the well-known association of β-*N*-acetylglucosaminidase with hyaluronidase in the testis, parallel measurements of the latter enzyme were carried out turbidimetrically[4].

Considering the four simple glycosidases, the most striking feature is the enormously high activity of β-*N*-acetylglucosaminidase in boar epididymis, making this a most convenient source of the enzyme (total weight of tissue from one animal 200 gm.). Very high figures for this enzyme have been recorded in boar semen and epididymal secretion[5]. The figures for β-glucuronidase in boar testis and epididymis are in accord with the statement of Sarkar and Sumner[6] that liver, kidney and spleen are remarkably low in this enzyme in the pig compared with other mammalian species; their method of assay, however, precluded comparison with the results of other workers. Our own figures for pig liver, kidney and spleen were 170, 20 and 110 phenolphthalein units per gm., respectively, which are indeed low for these organs; the non-ionic surface-active agent 'Triton *X*-100' did not increase these figures[7]. So far as α-mannosidase, β-galactosidase and β-*N*-acetylglucosaminidase are concerned, it was found that the activities in these pig tissues were of the same order as corresponding values in the rat[1].

In infant bull and boar testis and epididymis, the general relationship observed for all four simple glycosidases in the rat[1] appeared to hold; whereas the testis figures were equal to, or greater than, the adult ones, the epididymal figures were very much lower.

It can be seen that, in general, the epididymis is at least comparable to the testis as a source of hyaluronidase, but the figure for boar epididymis does not reflect the β-*N*-acetylglucosaminidase value of this tissue.

Distribution of Kappa-Casein in Skim Milk

RECENTLY, it has been reported that, by differential centrifugation of skim milk, one may obtain casein fractions which differ in their stability toward calcium but which appear identical by electrophoretic analyses[1]. Since the casein micelles are stabilized by kappa-casein[2] and this component is not readily detected by electrophoretic analysis, it appeared that a probable explanation for the above observations is that kappa-casein is not evenly distributed in the micelles of varying size. It is the purpose of this communication to report experimental verification of this hypothesis.

By differential centrifugation of raw skim milk in a fixed-angle rotor, six fractions were obtained containing from 10 to 90 per cent of the total casein. Each fraction was purified by careful solubilization, precipitation at *p*H 4·6, filtration, and thorough washing with distilled water. Casein from the original skim milk was recovered in a similar manner. Electrophoretic analyses revealed no significant differences between the original casein and any of the subfractions.

The whole casein and the six casein fractions, obtained by centrifuging, were hydrolysed with dilute sulphuric acid[3] after which the concentration of N-acetylneuraminic acid was determined by the colorimetric procedure of Svennerholm[4]. The analyses demonstrated a linear increase in the concentration of N-acetylneuraminic acid as progressively more casein was centrifuged from the milk. However, the sample containing 90 per cent of the casein failed to account for 90 per cent of the N-acetylneuraminic acid found in the isoelectric precipitate from the original milk. Therefore, in a second experiment, 86 per cent of the casein was removed by centrifugation and the supernatant liquid was examined. After the casein in this solution had been precipitated and thoroughly washed, analysis for N-acetylneuraminic acid revealed a concentration that was more than twice as great as that found in whole casein recovered from the same lot of skim milk.

A plot of mgm. of N-acetylneuraminic acid per gm. of casein versus per cent casein centrifuged, fitted by the method of least squares, yielded the following relationship:

$$\text{mgm. N-acetylneuraminic acid/gm. casein} = 2{\cdot}61 + 0{\cdot}0156 \times (\text{per cent casein centrifuged})$$

Since about 8 per cent of the casein is non-centrifugable, the above expression was used to calculate the concentration of N-acetylneuraminic acid for each increment of 8·33 per cent of the casein. Based on the results of Waugh[5], Nitschmann[6], and Wake[7], it was calculated that 28·7 mgm. of the acid should corre-

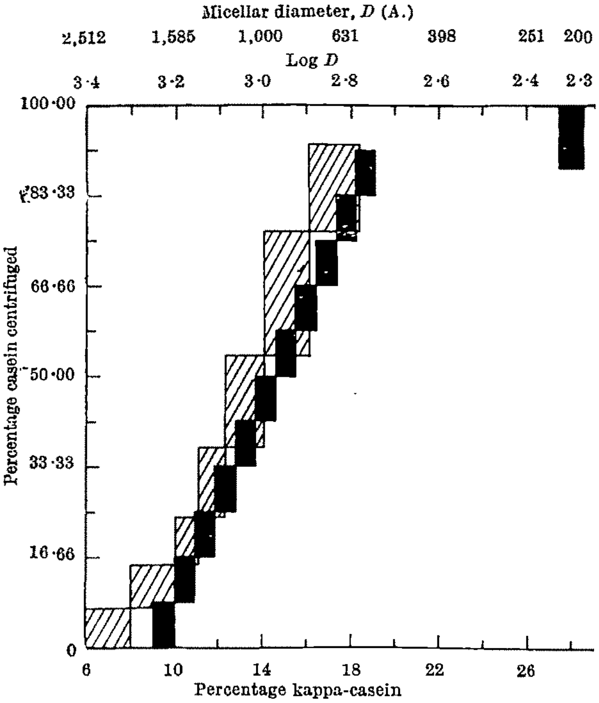

Fig. 1. The size of the casein micelles (shaded blocks) and their content of kappa-casein (solid blocks) as a function of percentage casein centrifuged from skim milk

spond to 1 gm. of kappa-casein. This would account for 15 per cent kappa-casein in whole casein, and the analyses of two samples of whole casein yielded a value of 16 per cent using this factor. The kappa-casein concentrations, calculated in this manner, are shown in Fig. 1 for eleven increments of centrifugation. Although the composition of the soluble casein was obtained from an experiment in which only 86 per cent of the total casein had been centrifuged instead of 92 per cent, it appears that this fraction represents a distinct break from the trend observed with micelles of varying size. The analysis indicates that the non-centrifugable casein may contain as much as 28 per cent kappa-casein.

Since kappa-casein is the component responsible for the stabilization of the casein micelles, perhaps it is not surprising to find a correlation between the concentration of this component and the particle-size distribution of the casein micelles. While the change in concentration of kappa-casein with each increment of casein that is centrifuged demonstrates this relationship, a more direct comparison may be made making use of some unpublished results from this laboratory on the particle-size distribution of the casein micelles. These results were also obtained by differential centrifugation of skim milk in a fixed-angle rotor. The diameters of the micelles were calculated assuming a difference in density of 0·084 between the micelles and serum. The results were corrected for the accumulation of small particles, based on the analysis of gravitational sedimentation[8]. Because of wall effects and possible convection in the fixed-angle rotor, the final analysis must be considered as only an approximate representation of the particle-size distribution. In preparing the frequency distribution curve, it was noted that this became very nearly symmetrical if plotted against the logarithm of the diameter. Therefore, in Fig. 1, a logarithmic scale has been used for the abscissa. The correlation with the results on kappa-casein is quite satisfactory. A detailed description of this work will be published in the near future.

Effect of Amniotic Fluid on Inhibition of Growth by Cortisone in Chicken Embryos

The fact that cortisone has an inhibitory effect on growth of chicken embryos was first noted in 1947[1]. A detailed study of this phenomenon was afterwards undertaken by Karnofsky, Ridgway and Patterson[2] and their observations were confirmed by Yamada[3] and by Siegel, Smith and Gerstl[4]. Cavallero, di Marco, Fuoco and Sala[5] secured evidence indicating that the growth-inhibiting effect of cortisone is brought about by an interference with protein synthesis, and an excess of hydroxyproline found by Roberts, Karnofsky and Frankel[6] after cortisone treatment presumably points to the same conclusion. In experiments with weanling rats, Tuchmann-Duplessis and Mercier-Parot[7] failed to counteract the growth-inhibitory action of cortisone by concurrent treatment with somatotropic pituitary hormone, glucosamine or the polysaccharide fraction of human placenta. In chicken embryos, on the other hand, Sobel[8] observed that the deleterious effects of cortisone on growth and survival were partially counteracted by simultaneous administration of somatotropic pituitary hormone.

Montgomery[9] found in baby chicks that the growth-retarding effects of cortisone could be reversed to some extent by injecting beef amniotic fluid in addition to cortisone. A similarly favourable result was obtained by de Franciscis and Magri[10] in young rats treated with cortisone which received simultaneously human amniotic fluid. Subsequent studies by de Franciscis, Magri and Verdoliva[11] established that the cortisone-counteracting properties of the amniotic fluid were bound to protein. We have now made tests to determine if amniotic fluid also has a favourable effect if given subsequent to treatment of chicken embryos with cortisone.

We used in our tests the eggs of White Leghorn fowl and, for treatment, cortisone acetate (Merck) and beef amniotic fluid. The test fluids were injected into the yolk sac after 8 days of incubation. 1·73 mgm./egg cortisone acetate (0·07 c.c. of a 25 mgm./c.c. solution) and 0·15 c.c. amniotic fluid were used. All eggs were opened, and the living embryos were weighed after 18 days of incubation. In a preliminary test we could confirm the growth-retarding effect of cortisone. The weight of 59 control embryos was 20·34 ± 0·37 gm., that of 59 cortisone-treated embryos was 15·43 ± 0·33 gm., with a highly significant difference of 4·91 ± 0·52 gm. between the two groups. Amniotic fluid alone, on the other hand, had no effect whatever on body-weight, the mean weight of the 59 control embryos being 20·34 ± 0·37 gm., whereas that of 84 embryos treated with amniotic fluid amounted to 20·30 ± 0·36 gm. The effect of amniotic fluid on inhibition of growth by cortisone was tested in two experiments. Since there was no significant difference in the results of these tests, the results were pooled. The mean weight of 41 cortisone-treated embryos was 14·02 ± 0·63 gm.; for 63 embryos treated with both cortisone and amniotic fluid the mean weight was 16·18 ± 0·46 gm. The difference amounted to 2·16 ± 0·78 gm. and was highly significant. It is important to note that there was no significant difference between the two groups in post-treatment mortality or in the incidence of gross malformations. As in the earlier tests with rats, it can therefore be concluded that in developing chicken embryos amniotic fluid reduces in a limited, but significant, manner the cortisone-induced retardation of growth. It remains to be determined whether the beneficial effect of amniotic fluid and the similar but more significant one of pituitary growth hormone on retardation of growth following treatment with cortisone is mediated via the endocrine system or, perhaps more likely, is due to an unspecific stimulation of growth.

Effect of Streptomycin on the Incorporation of Amino-Acids labelled with Carbon-14 into Ribonucleic Acid and Protein in a Cell-free System of a *Mycobacterium*

DURING investigations on the effect of streptomycin on the protein synthesis in *Mycobacteria*, it was observed that streptomycin inhibited the incorporation of ^{14}C-DL-tyrosine into the protein of resting cells of a streptomycin-sensitive strain of *Mycobacterium friburgensis* while it had no such effect on the resistant strain (Table 1).

As phosphorus-32 is incorporated into ribonucleic acid at the same rate in presence and in absence of streptomycin, the site of inhibition is most probably in the synthesis of protein itself. This possibility was tested in a cell-free system.

Table 1. INCORPORATION OF ^{14}C-DL-TYROSINE INTO PROTEINS OF THE INTACT CELLS OF *Mycobacterium friburgensis*
In each tube, 200 mgm. wet weight washed cells suspended in 1·5 ml. asparagin-free Sauton medium were incubated for 30 min. at 37° in a total volume of 2 ml. with 2 μc. ^{14}C-DL-tyrosine, with or without the addition of 100 μgm. dihydrostreptomycin

No.	Strain	c.p.m./mgm. protein	
		Without streptomycin	In presence of streptomycin
1	Streptomycin-sensitive	1,310	735
2	,, ,,	750	406
3	,, ,,	1,135	535
4	Streptomycin-resistant	535	730
5	,, ,,	153	217
6	,, ,,	735	750

Hoagland *et al.*[1] have shown in a cell-free system from rat liver that amino-acids are first bound by a soluble ribonucleic acid and are afterwards transferred to microsomal protein. F. Gros (personal communication) found that the soluble ribonucleic acid in a cell-free system isolated from *E. coli* incorporated amino-acids.

Preparation of a cell-free system of *M. friburgensis* was carried out by Gros's method (private communication), with minor modifications.

The extract of disrupted bacteria was centrifuged at 105,000*g* for 60 min. To the supernatant, 0·5 *M* acetic acid was added to bring the *p*H to 4·5. The resulting precipitate was redissolved in a buffered medium[2]. This preparation was incubated at 37° C. in the presence of ^{14}C-DL-tyrosine and adenosine triphosphate, with and without the addition of streptomycin. Both the protein and the ribonucleic acid were isolated and their radioactivity determined, according to the methods described by Hoagland *et al.*[1].

The results of an experiment with cell-free systems obtained from streptomycin-sensitive and -resistant strains are shown in Fig. 1.

The extent of incorporation of tyrosine labelled with carbon-14 into ribonucleic acid was markedly stimulated in both cases by the addition of streptomycin. On the other hand, streptomycin inhibited labelling of protein in the cell-free system from the

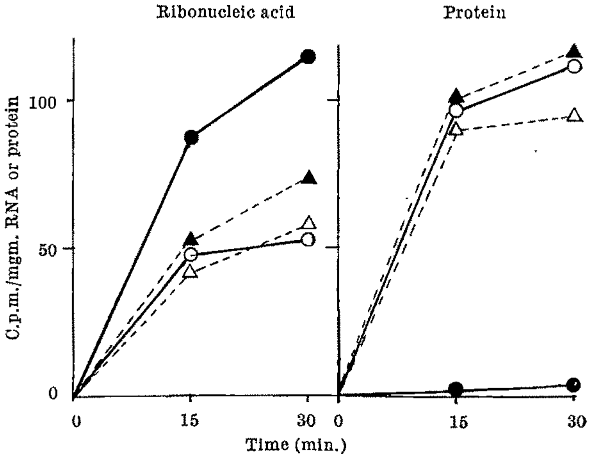

Fig. 1. Labelling of ribonucleic acid and protein with ^{14}C-DL-tyrosine in a cell-free system of streptomycin-sensitive and -resistant strains of *Mycobacterium friburgensis*. In each tube 0·5 ml. of the *p*H 4·5 precipitate (prepared from 1 gm. wet weight cells) dissolved in 1 ml. buffer (ref. 2) was incubated for 15 and 30 min. at 37° in a total volume of 2 ml. with 3 μc. ^{14}C-DL-tyrosine, in presence of 0·01 *M* adenosine triphosphate, with or without the addition of 200 μgm. dihydrostreptomycin. ○, Sensitive strain; ●, sensitive strain in presence of streptomycin; △, resistant strain; ▲, resistant strain in presence of streptomycin

sensitive strain, but did not affect the extent of labelling of protein in the cell-free system of the resistant strain.

This finding points to the specific nature of the inhibition even though the labelled protein fraction is hitherto not characterized. The present results suggest that streptomycin inhibits the transfer of amino-acids from ribonucleic acid to protein.

PLANT PHYSIOLOGY

Non-respiratory Gas released from Seeds during Moistening

Several investigators have observed that many species of seeds seem to have a relatively high respiratory quotient (R.Q.) soon after they begin to take up water and that the R.Q. decreases and finally levels off with increasing time of imbibition. Stiles and Leach[1] consider such R.Q. variations indicative of shifting metabolic pathways within the seed. Crocker and Barton[2] emphasized that gaseous exchanges of intact seeds do not necessarily reflect actual metabolism. James[3] suggested that these variations in observed R.Q. might be explained by irregularities in oxygen absorption. Our results show that gas, presumably air adsorbed within the seeds, is given off as the tissues become wet. This physical effect may provide another explanation for the shifting values of the apparent R.Q. during imbibition.

Seeds or other materials were placed in the main compartment of a Warburg flask (~ 20 ml. vol.) with 1·0 ml. distilled water, previously boiled to expel dissolved gases, in the side-arm. Flasks were attached to manometers and allowed to stand for equilibration for 15 min. before being closed. After at least 10 min. more, the water from the side-arm was tipped on to the seeds in the main compartment. Gaseous exchange was determined with the Warburg constant-volume respirometer as described by Umbreit *et al.*[4].

Fig. 1 (curves *A*, *B* and *C*) illustrate gas output of Grand Rapids lettuce seed immediately after wetting. That this is not an artefact produced by the tipping process is shown by the steady behaviour with 0·1 ml. of glass beads similarly treated (curve *D*). The seeds in contact with a water-saturated atmosphere for 60 min. (curve *B*) or 120 (curve *C*) min. seemed to produce some gas before the water was tipped from the side-arm. The total net gas produced (curves *A*, *B*, *C*) before and after tipping seemed to be constant, suggesting that the release of gas is a physical phenomenon. Within the limits of experimental error, the results were the same with 0·2 ml. of 20 per cent potassium hydroxide as with 0·2 ml. of distilled water in the centre well, indicating that little or no carbon dioxide was produced. The volume of gas released was calculated from the pressure changes with the assumption that the gas had the water-solubility characteristics of air. This assumption would lead to errors of less than 1 per cent in calculated gas volumes if the gas contained nitrogen, oxygen, hydrogen, carbon monoxide, or nitric oxide in any combinations or proportions. This phenomenon appears to be essentially completed several minutes after the wetting (Fig. 1). Respiratory gas exchange during these few minutes is probably negligible, since we have found $Q_{O_2} \approx 1$ µl./min./100 seeds at 37° C. for fully imbibed (4½ hr.) seeds. The amount of gas released from Grand Rapids lettuce seeds after wetting increased with increasing temperature (Table 1).

Table 1. Gas produced within 10 min. after wetting Grand Rapids Lettuce Seeds at Different Temperatures

* Viable.
† Rendered non-viable by heating at 95° C. for 12 days.
‡ Killed (after 3-hr. imbibition) by freezing then heating to 95° C. for 10 days.

Similar experiments with different materials are reported in Table 2. Non-viables seed, which neither germinated nor respired, showed the effect, as did dried tea leaves and potato starch. Therefore the phenomenon observed with viable seeds seems to be a general property of dry plant material.

The gaseous output observed when dried material was moistened cannot be explained by simple displacement of air at atmospheric pressure, since in this case the total pressure of the system would remain unchanged. Thus the gas was either trapped under pressure or it was adsorbed upon surfaces within the material. Because of the variation of output with temperature (Table 1) and also because the volume of gas released at 37° C. was approximately twice the total volume of the dry seeds, we favour the explanation in terms of colloidal adsorption[5].

The pertinence of this physical phenomenon to the experimental determination of R.Q. values is obvious. Non-respiratory evolution of gas as described here would lead to calculation of mistakenly high R.Q. values. Fig. 1 suggests that this non-respiratory phenomenon can occur over a period of several hours when seeds are moistened slowly. To illustrate our argument, we note that peas have been reported to

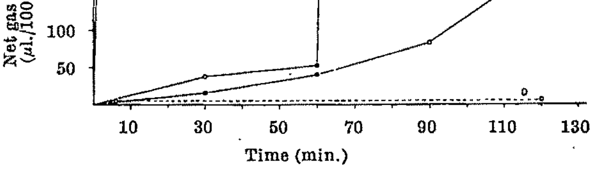

Fig. 1. Gas released from lettuce seeds at 37° C. Seeds were kept in a water-saturated atmosphere until moistened at times indicated

have the exceptionally high R.Q. of 6·0 after a 4-hr. soaking, with a decrease to 1·8 after 8 hr., and a further decrease with increasing time[2,3]. Allerup[6] showed, however, that it takes approximately 18 hr. for peas to complete their imbibition of water. Thus it may be suggested that non-respiratory gaseous output during wetting accounted for the high apparent R.Q. values reported after 4 and 8 hr.

These experiments suggest certain precautions for studies of respiration of intact seeds and similar biological material. Examination of the literature suggested that this unrecognized non-respiratory gas output in many instances led to mistakenly high apparent R.Q. values before water imbibition had been completed.

A Two-Stage Fermentation of Cassava

ONE of the staple foods of the people of the rain forest belt of West Africa is gari, a starchy food prepared from the root of the cassava plant (*Manihot utilissima*). The traditional preparation of gari[1] consists briefly of the following stages: both the corky outer peal and the thick cortex are removed; the body of the root is grated by hand on home-made raspers; the greater part of the juice is removed from the pulp by primitive pressing; the pulp is left in bags for 72–96 hr. before it is fried. During this time fermentation occurs; hand-made raffia fabrics are used for 'sifting'. A certain amount of fibre and ungrated ends of the roots are removed here. The pulp is afterwards heated in large iron pans over an open fire with or without the addition of palm oil.

We have recently been investigating the microbiology of the traditional preparation to determine the conditions needed for mechanized production of this foodstuff in Nigeria.

It is well known that the cassava root contains a cyanogenic glucoside which renders it poisonous if eaten fresh, and that during the traditional methods there is a holding stage during which this glucoside decomposes with liberation of gaseous hydrocyanic acid and after which the material is safe to eat.

The presence of hydrocyanic acid in cassava roots was first recorded by Boutron Chalard in 1836 [2]; but it was found that the acid is not present in cassava roots in its free state but in the form of a glucoside[3]. This was later found to be identical with the glucoside present in the beans of *Phaseolus lunatus*, phaseolunatin[4]. The precise nature of the process by which the glucoside is broken down, and what, if any, other changes occur during the holding stage, which lasts three or four days, is not clearly stated. It has been suggested that the glucoside is hydrolysed by the same mixture of enzymes as is present in the beans of *Phaseolus lunatus*[4]. In a more recent publication[5] Oyenuga and Amazigo refer to the glucoside as "linamarin" and to the enzyme responsible for its hydrolysis as "linase".

We have succeeded in preparing partially purified cyanogenic glucoside from the pressed juice of cassava roots, using the cortex and the inner flesh, from which the starch and other suspended matter were removed by centrifuging followed by filter pressing. This juice was found to contain 0·0045 per cent hydrocyanic acid, that is, its glucoside content is of the same order as that of the cortex of bitter cassava. The material was free from protein and may therefore be regarded as uncontaminated with any plant enzyme. This material is very unstable and undergoes spontaneous hydrolysis at *p*H's less than 7. During its isolation the glucoside was stabilized with potassium hydroxide and the sugars were removed with Fehling's solution until all reactions for sugars were negative. The compound was then purified by crystallization from alcohol. The purified glucoside hydrolysed spontaneously after acidification, liberating hydrocyanic acid and glucose.

Further, we have consistently isolated two organisms from grated cassava during the holding stage of the traditional preparation of gari: (*a*) A member of the genus *Corynebacterium* characterized by the production of yellow colonies on nutrient agar, and the fermentation of starch with the production of acid only. This organism does not appear to be recognized in Bergey's "Manual of Determinative Bacteriology", and the specific name of *Corynebacterium manihot* is suggested for it. (*b*) The fungus *Geotricum candida*.

The *Corynebacterium* was found in increasing numbers during the first 48 hr. of the fermentation, and was then replaced by the *Geotricum*, which by the third or fourth day was the predominant organism.

We therefore suggest that the process of detoxification of cassava root that occurs in the preparation of gari should be regarded as a two-stage fermentation. In the first stage the *Corynebacterium* attacks the starch of the root with the production of various organic acids, and the lowering of the *p*H causes spontaneous hydrolysis of the cyanogenic glucoside with liberation of gaseous hydrocyanic acid. When sufficient organic acids, including lactic acid, have been produced, conditions become favourable for the growth of the *Geotricum*, and this then proliferates, producing a variety of aldehydes and esters. These last products appear to be responsible for the characteristic taste and aroma of the gari.

Acting on the two-stage fermentation hypothesis, we have prepared gari in 24-hr. using as starters a mixture of pure cultures of the two organisms mentioned above, and this product has been tested by feeding it to volunteers. They were unable to tell the difference between the gari produced in 24 hr. by the use of the pure culture starter and the traditional product produced by 4 days holding. We have also found it possible to shorten the fermentation to 24 hr. by using as a starter pressing water from the first stage in the preparation of the roots which had been kept at room temperature for 4 days, and which, on examination, was found to contain enormous numbers of both the *Corynebacterium* and the *Geotricum*. A description of this starter technique has been published in a report on improved methods of preparing gari circulated by the Federal Ministry of Commerce and Industry, and the method is being adopted by some co-operative societies.

Further work on the chemistry of the cyanogenic glucoside is in progress and will be published elsewhere. A full account of the new species of *Corynebacterium* is in preparation and will be submitted for publication elsewhere.

We wish to thank Mr. K. R. Butlin, National Chemical Laboratory, Teddington, for kindly checking the characteristics of the two organisms.

AGRICULTURAL SCIENCE

Spraying of Barley with 2,4-Dichlorophenoxyacetic Acid

DR. H. INGVARD PETERSEN has discovered differences in the translocation of the plant growth regulator herbicides applied to cereal plants of different ages[1]. His autoradiographs show that whereas radioactive 2,4-dichlorophenoxyacetic acid applied to barley at the one- to three-leaf stage is readily translocated to all parts of the plant, including, presumably, the growing point, application to successively older plants results in progressively less translocation. This plant growth regulator herbicide applied to the fifth and sixth leaves of a five- to six-leaf plant appears to be translocated to a very limited extent indeed.

I note with interest Dr. Petersen's conclusion that this may account for the fact that cereals do not develop deformed heads after treatment with 2,4-dichlorophenoxyacetic acid at the five- to six-leaf stage, whereas treatment at earlier stages leads to interference with the pattern of differentiation of the spikelet primordia and deformed heads. Hitherto it had been thought that the leaf and spikelet primordia are sensitive to damage by the plant growth regulator herbicides when first initiated but become progressively resistant as their development proceeds. In view of Dr. Petersen's alternative explanation, it is worth while to examine more closely the evidence for this latter concept.

Fig. 1 shows photomicrographs of the growing point and developing spike of barley sprayed with 2,4-dichlorophenoxyacetic acid at a series of stages between one and six leaves. The apices were dissected and photographed some days after treatment.

Plant 1 was sprayed when the ultimate leaf initial was appearing, that is, just before transition to the reproductive stage. The plant had one expanded leaf and the second was emerging. The small arrow points to the developing leaf primordium which can be seen to be a 'ring' of tissue completely encircling the stem. This is the aberrant type of cell differentiation which gives rise to the 'tubular leaf' abnormality. (Normally, growth of a leaf primordium is restricted to one side of the stem and the leaf margins are free, not fused as in the 'tubular leaf'.)

Plant 2 was sprayed when transition to the reproductive phase had just taken place and the lower spikelet primordia were in the early phase of development, characteristically the 'double ridge' stage, but were not organized further. As may be seen, these lower primordia are grossly aberrant (arrow). They would give rise to the 'opposite spikelets' or 'whorled spikelets' abnormality or may be abortive. It should be noticed, however, that the ultimate leaf is apparently developing quite normally and from experience it is known that it will give rise to a normal leaf. It is suggested that by the time of the treatment it had already developed to a stage when it was no longer susceptible to damage by the synthetic growth regulator.

Plant 3 shows the effect of spraying when subsequent spikelet primordia were at the very early phase of development but when the lower, first formed, spikelet primordia had progressed somewhat. Clearly, the subsequent spikelet primordia are severely affected (arrow) but the lower ones are developing quite normally. It is suggested that these lower spikelets had progressed beyond the sensitive phase when the growth regulator was applied. Lack of translocation can scarcely account for the lack of

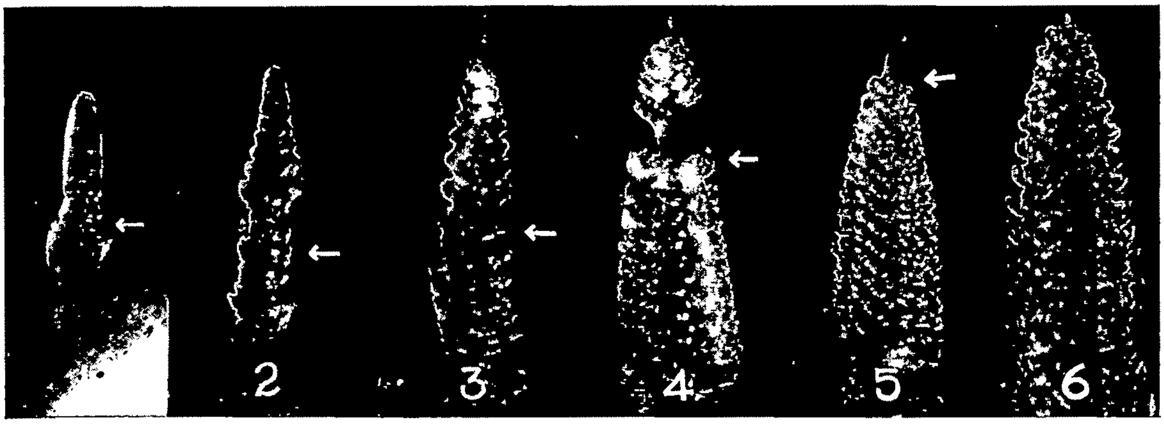

Fig. 1. Photomicrographs of the growing point and developing spike of barley plants sprayed with the equivalent of 0·5 lb. per acre of 2,4-dichlorophenoxyacetic acid. Plant 1 was sprayed when the growing point was vegetative and had the second leaf just visible. Plants 2, 3, 4, 5 and 6 were sprayed at a succession of stages during the reproductive phase. The most advanced, plant 6, had five to six leaves when sprayed

effect on these lower spikelets since those developing higher on the rachis were affected.

Plant 4, which was sprayed at a later stage, demonstrates this point still further, and plant 5 shows the effect of spraying when only the last few spikelet primordia remained to be initiated before the growing point ceased to grow.

Plant 6 was sprayed when all the spikelet primordia were laid down and had progressed beyond the early phase of their initiation.

In every case the spikelet primordia below the point of abnormality have developed quite normally, and it is known that in practice they produce normal fertile flowers and seed. Thus it appears to me that, while Dr. Petersen's work may show translocation to be a contributory factor in the increasing resistance of barley with age to damage by the plant growth regulator herbicides, the age (or more correctly the stage of development) of the leaf or spikelet primordia must still be regarded as a major factor governing susceptibility to damage.

A great deal of work has been carried out here on the effect of the plant growth regulator herbicides on cereals and it has been found that the situation is highly complex. We have found considerable variation to occur in the behaviour of different growth regulators. For example, in barley, α(2 : 4-dichloro-3-methylphenoxy)propionic acid and α(2 : 4 : 5-trichlorophenoxy)propionic acid both cause spikelet abnormality (usually sterility) even when applied at a late stage of primordial development, while others, such as α(4-chloro-2-methylphenoxy)propionic acid, cause relatively little abnormality even when applied at the most sensitive stage. Work is in progress, using carbon-14 labelled growth regulators, to attempt to resolve the causes of these differences. I am indebted to Dr. Petersen for bringing to my notice the important part that translocation may play.

'Karathane' : the Value of its Differential Fungicidal Effect in Relation to Mildew and Yellow Rust of Wheat

EXPERIMENTAL work with yellow rust (*Puccinia glumarum* (Schm.) Erikss. and Henn.) on wheat seedlings under glasshouse conditions has been considerably hampered by epidemics of cereal mildew (*Erysiphe graminis* D.C.). Control of these epidemics has proved difficult because environmental conditions in a normal glasshouse cannot be kept within narrow limits and because fungicides which have been effective against the mildew have also been toxic to the rust. Reports of the effectiveness of 'Karathane' (2 : 4-dinitro-6-(1-methyl heptyl) phenyl crotonate) when used either as a wettable powder or as a fumigant for the control of many powdery mildews but no other disease prompted us to examine the possibility of its being of use in this instance.

A number of seedlings bearing uredosori of yellow rust were fumigated with 'Karathane' when the first mildew pustules appeared. Subsequent development of both diseases was compared with that on similar, untreated seedlings. The flush of mildew pustules, which typically follows 4–5 days after the initial infection, occurred on the untreated seedlings but not on those fumigated. Mycelial growth of the mildew was not entirely suppressed but the pustules were thinner and more widespreading than normal. The yellow rust was apparently unaffected and continued to produce uredosori in a typical zonation.

In subsequent experiments it was found that both rust-resistant and rust-susceptible seedlings fumigated with 'Karathane' 1–10 days before and 2–10 days after inoculation with uredospores gave the anticipated host reaction. Furthermore, uredospores taken from plants only 20 hr. after fumigation successfully infected the seedlings to which they were inoculated.

A microscopical examination of both fungi was made 20 hr. after fumigation. The yellow rust uredospores from treated and untreated seedlings were indistinguishable, but some differences were noted in the mildew spores. Oidia were stained with cotton blue in lacto-phenol before examination. Those from treated plants had a granular, unevenly stained cytoplasm and the nuclei were well stained and clearly visible. Some bursting and irregularities of the spore wall was also noted. Oidia from untreated plants were more uniformly and more densely stained and consequently the nucleus was not as clearly visible.

During experiments with seedlings it was found that the mildew could be kept under control without any adverse affects on the yellow rust for a period of at least 8 weeks by regular fumigation with 'Karathane' immediately fresh mildew pustules appeared. Under the conditions prevailing during the experimental period, this was at about 10–12 day intervals.

BIOLOGY

Œstrous Cycle, Gestation Period and Parturition in the Marsupial *Trichosurus vulpecula*

COLONIES of the brushtailed possum, *Trichosurus vulpecula* Kerr., a marsupial, have been kept in Sydney since May 1954 and in Adelaide since January 1957. Breeding seasons were studied, in both places, in the local wild populations from which the captive animals were derived. Breeding in the Sydney colony began in June 1955 and in the Adelaide colony in March 1957. To date 46 specimens (including 16 second-generation young) have been born in captivity. Only one young is normally reared each year in the wild in the Sydney area, but it seems that many wild females in the Adelaide area rear two young each year.

T. vulpecula is polyœstrous. Daily vaginal smears were taken from 13 females in the Adelaide colony over periods of up to 10 weeks. In these the œstrous cycle varied in length from 21 to 30 days (average 24½ days). Œstrus did not occur in lactating females with young in the pouch, but if the pouch-young were removed such females came into œstrus between 4 and 10 days later. Females which lost pouch-young often produced a second young soon afterwards, although no female in the Adelaide colony conceived at the first œstrus after the cessation of lactation. However, a female in the Sydney colony is presumed to have conceived at this time for it produced two offspring within about one month, the first young having been lost when less than 8 days old. Two captive females are known to have reared two offspring each in one year.

The gestation period in 3 animals in the Sydney colony was between 17 and 21 days. The interval between the appearance of sperms in the daily vaginal smear and parturition was between 16 and 17 days in one Adelaide female and 17–18 days in two others. Since copulation occurred some time prior to smearing, the gestation period is assumed to be about 17½ days. The gestation period of *T. vulpecula*, like that of the American opossum *Didelphis virginiana*[1] and the wallaby *Setonix brachyurus*[2] is thus shorter than the length of one œstrous cycle.

On July 28, 1958, one of us (A. G. L.) witnessed parturition in *T. vulpecula*. The female showed signs of restlessness and thereafter put herself in a sitting position, facing the front of the cage with the hind-limbs partly extended. Fluid exuded from the urogenital opening and an embryo, free of fœtal membranes, was expelled, followed by more fluid. Unfortunately, the embryo fell from its mother through the wire-mesh floor of the cage into a tray of sawdust. The mother then licked the urogenital opening. She was then taken from the cage, held on her back in a horizontal position, and the young recovered from the sawdust, washed with normal saline, and returned to the region of the urogenital opening. The young turned to face the direction of the pouch and crawled through the fur by alternate over-arm movements of the fore-limbs. The posterior margin of the pouch, approximately 7 cm. from the urogenital opening, was reached in 7 min.; the distance would have been less if the mother had been held in a sitting position. The young did not immediately enter the pouch but continued to its anterior margin—a further distance of about 4 cm. It then turned round and crawled back to the posterior margin, where it again turned and proceeded forward several centimetres before entering the pouch. A slight relaxation of the pouch opening was noticed when the young was crawling at the margin. A period of 5 min. elapsed from the time of arrival at the posterior margin to the time of entry into the pouch. After the young had entered it crawled about but was unable to gain either of the two teats, although it tried for a period of approximately 20 min. It was then removed, weighed, photographed and examined before fixation.

Earlier descriptions[3-5] of parturition in marsupials suggested that the female licked a track in the fur from urogenital opening to pouch, up which the young climbed. In this instance the mother neither licked the fur nor assisted the young in any other way. This is in keeping with recent observations on birth in *Didelphis*[1].

The new-born *T. vulpecula* observed was 13 mm. in crown–rump length (measured between 2 parallels) and 6 mm. in head-length. Its weight was 0·20 gm. and its mother's weight 2,030 gm. Another specimen removed from the pouch a few hours after birth (Adelaide colony) was of comparable size and weighed 0·21 gm. In the first specimen the ratio, weight of newborn to weight of mother, was less than 1 : 10,000. Ratios for other mammals vary from 1 : 60,000 for kangaroos to as high as 1 : 3 for some bats[6].

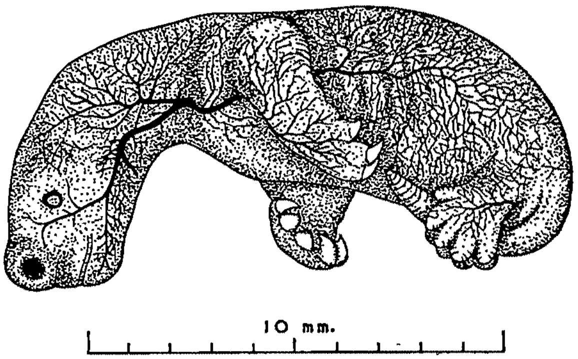

Fig. 1. *Trichosurus vulpecula*. New-born unattached young. Note the conspicuous blood vessels as seen through the integument in the living specimen, and the strongly developed fore-limbs, with claws, which are used for climbing into the pouch

The living new-born was semi-transparent and pinkish in colour with a conspicuous network of blood vessels visible through the skin (Fig. 1). The fore-limbs were strongly developed, and all digits of the manus were equipped with well-developed sharp-pointed claws turned inwards towards the palm. As the fore-limbs alone were used in climbing into the pouch these claws appear to be important structures which aid the young to grip the mother's fur. The new-born young continued to make crawling movements and was observed to flex the digits of the manus, after removal from the pouch. Well-developed claws formed by the epitrichium were observed on the fore-limb digits of *D. virginiana*[6], the native cat *Dasyurus quoll*[7], and the bandicoots *Perameles gunnii* and *Isoodon obesulus*[8], but these were shed soon after birth. Those of *T. vulpecula* are also of epitrichium but are still present 5 weeks after birth and probably persist much longer. It has been suggested[9] that the claws of *T. vulpecula* are not shed during pouch life as are those of other species.

The hind-limbs were not as well developed as the fore-limbs. The plantar surfaces were directed towards the mid-ventral line, and the partly separated digits of the pes were distinct. Claws were not discernible. The oral aperture was oval to circular in shape, the lips being fused to form the characteristic sucking mouth of juvenile pouch-young. The pigmented portion of the eye could be seen through the epitrichium that covered the whole body. The nostrils were well developed, but the folded pinna of the ear could only be discerned with difficulty. Part of the umbilical cord was still attached. It was not possible to sex the new-born as neither pouch nor scrotum was developed.

A Relationship between some Bacteria, Protozoa and Diet in Early Weaned Calves

EARLY weaning of calves on to a solid diet is now becoming more common, and investigation of the establishment of ciliate protozoa in calves reared according to Preston's system[1] indicated that although numerous ciliates might be established by the end of the second week when only milk and roughage were being fed, these disappeared immediately a large proportion of concentrates was included in the diet. Microscopic observations suggested that the numbers of ciliates were inversely related to the numbers of *Lactobacilli*, which were directly related to the proportion of concentrates in the diet. It thus seemed of interest to investigate the influence of diet on the flora and fauna of early weaned calves, as the establishment of an adult rumen population might aid in the digestion of an adult diet. Some preliminary results on two calves fed widely different ratios of hay and concentrates are given here. The organisms selected for cultural study were those which previous results had suggested might be related in numbers.

The calves were inoculated by stomach tube at weekly intervals (from 8 days) with a concentrated suspension of rumen ciliates and associated bacteria, and thereafter samples were taken at weekly intervals for visual assessment of bacteria and protozoa and viable counts of three types of organisms. *Lactobacillus* species were counted by making serial ten-fold dilutions of the rumen contents into a semi-solid tomato–glucose medium[2]. The highest dilutions showing growth of Gram-positive, catalase-negative, non-nitrate-reducing, asporogenous rods were recorded. The other two were a large Gram-negative lactate-utilizing coccus[3], which has been shown to be one of the principal bacteria in the rumens of young calves and to be present only in small numbers in older animals[4], and *Veillonella gazogenes*[5], another lactate-utilizing coccus. Ten-fold dilutions were made in a semi-solid lactate-containing medium[4] and examined for growth after 2 days incubation at 38°.

The two Ayrshire bull calves were kept in similar environments under ordinary conditions and both fed whole milk alone to 7 days and weaned at 21 days. Dried grass was available to calf *A*, but was fed by bucket to calf *B* from 7 days. Concentrates (containing 8 mgm./lb. 'Aurofac 2*A*') were added to the diet of calf *A* from 15 days and the amount was increased to 1,800 gm./day by about 8 weeks. Calf *B* was offered, and completely consumed, a 3 : 1 mixture of the same dried grass and concentrates, which was increased gradually to appetite until by 13 weeks it was eating a total of 2,000 gm. Over a period of 4 days in the sixteenth week the weight of concentrates given to calf *B* was increased to 1,800 gm./day and the grass reduced to zero. Thereafter, the concentrates were kept constant and grass was made available *ad lib.* from the seventeenth week.

The *p*H values of the rumen contents of calf *A* were lower than those of calf *B*, but became more nearly 7 from the thirteenth week as the *Lactobacillus* counts decreased. The results of viable counts are shown in Fig. 1. The number of *V. gazogenes* remained relatively constant at about the adult-level whatever the diet. However, while the numbers of *Lactobacilli* and large cocci were about the same in each calf at the end of the period on milk alone, the subsequent numbers depended very much on the amount of concentrates in the diet, and this also affected the ciliate population. The mixed fauna established in calf *B* remained throughout the experiment, whereas the first appearance of ciliates in calf *A* after weaning was at 12 weeks old, and they reached the level found in *B* by about 17 weeks. The microscopic observations showed a varied bacterial population, other than the main types cultured, to be present in both calves from an early age, and suggested that some small Gram-negative organisms, other than *V. gazogenes*, varied in numbers inversely with the *Lactobacilli*. The rapid changes in diet of calf *B* at 16 weeks, although affecting the cultured bacterial populations, did not affect the protozoa, and direct observation at this time showed few typical *Lactobacilli* such as had previously been associated with a high cultural count. In some concentrate-fed sheep although *Lactobacilli* were cultured in numbers of up to 10^6/ml. rumen contents, few morphologically typical *Lactobacilli* were seen in films of the rumen contents.

These results again suggest that in normal circumstances the rumen flora and fauna are greatly influenced by diet and possibly other, at present unknown, factors, and that rumen inoculations can only be successful provided that the rumen environment is suitable for the development of the added organisms[6,7]. This has also been found to be the case in other animals as inoculations of the large coccus into older calves and sheep have failed to establish them in the rumen. The initial presence of some organisms might also influence the growth of others, and a possible relationship can be noted here between the lactate-producing *Lactobacilli* and the lactate-utilizing large cocci. However, other factors must be concerned in the final balance of the bacterial population, as the numbers of *V. gazogenes*, which might be expected to be more directly influenced by the avail-

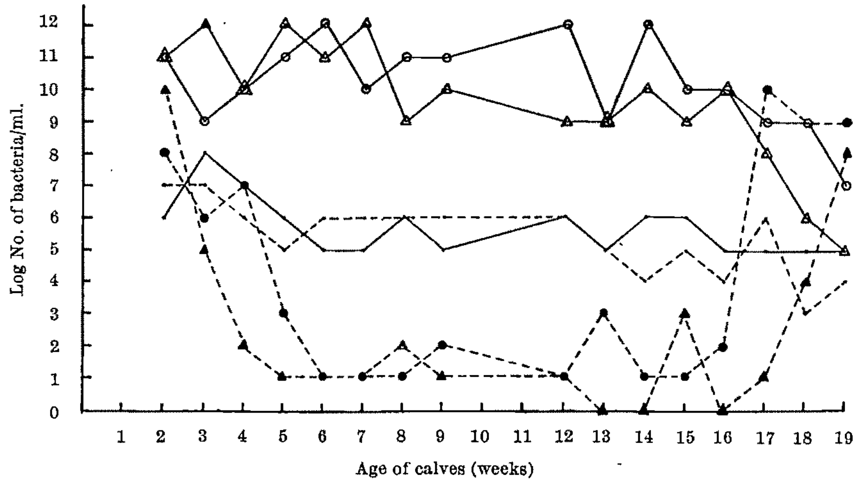

Fig. 1. Viable counts of some rumen bacteria in calves on different rations of hay and concentrates. Calf *A*, *Lactobacilli* –○–, large cocci –△–, *V. gazogenes* –•–. Calf *B*, *Lactobacilli* – – ● – –, large cocci – – ▲ – –, *V. gazogenes* – – • – –

able lactate, show little difference between the two animals.

We wish to thank Dr. T. R. Preston for providing and feeding the calves, and Miss S. Bell and Mr. W. Shand for technical assistance.

A Photographic Method for recording Activity and Behaviour in a Group of Small Animals

It is often desirable to obtain a quantitative measure of the activity of insects or other small animals over a specific period of time. Recently, an attempt was made[1] to overcome some of the inherent difficulties found when using the familiar mechanical methods for recording the activity of smaller insects. Moreover, Nielsen[2] reported a photographic method, which does not depend upon the mass of the insect, for estimating the number of changed positions in a group of mosquitoes at regular intervals. His method is especially suitable for use in darkness with insects that are affected by ordinary light but which do not respond to an electronic flash.

Nielsen's method has a disadvantage in that each photograph of the insects is compared with its predecessor to give an activity value based upon the number of insects which have changed position in the interval. Each number obtained from such a comparison contains within it an unknown factor, namely, the amount of movement of the insects occurring between the two exposures upon which the number is based. That is, each numerical item in the data contains an inherent unknown. In addition, comparison of adjacent exposures to determine which insects moved during the time-interval is a time-consuming task. It would probably exceed one's endurance to use this method often, for example, with exposures taken at 2-min. intervals over a period of 24 hr. Furthermore, the method is not suitable for use with large numbers of animals. Overlapping changes in positions with time would frequently confuse the interpretation.

During some studies in this laboratory it has been necessary to monitor the amount of movement in a group of adult *Drosophila melanogaster* Meig. over relatively long periods of time. The photographic method used employs a slow shutter speed to determine the number of insects in the group which are not moving when each record is taken. With this method each photographic exposure is autonomous, providing in itself a useful number with no inherent unknown motion factor, without the need for comparing it with its predecessor. It is possible, therefore, to examine a large number of negatives in a relatively short time. In addition, the principle of a slow shutter speed will allow relatively large numbers of animals to be used in the experimental container if desired.

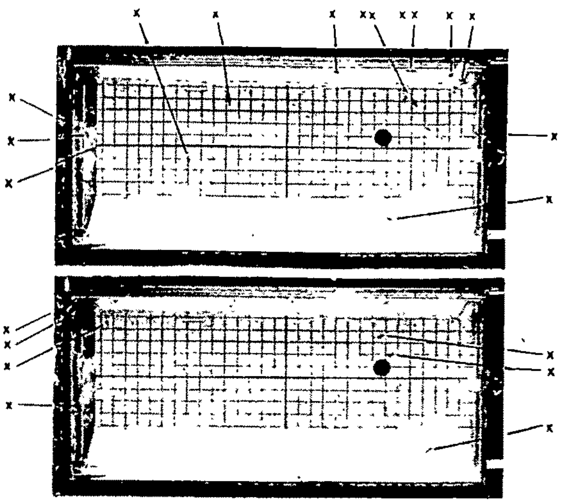

Fig. 1. 1-sec. exposures of box containing 15 insects. *x*, One stationary insect. Top, 14 insects stationary at 1745 hr.; bottom, 7 insects stationary at 2100 hr.

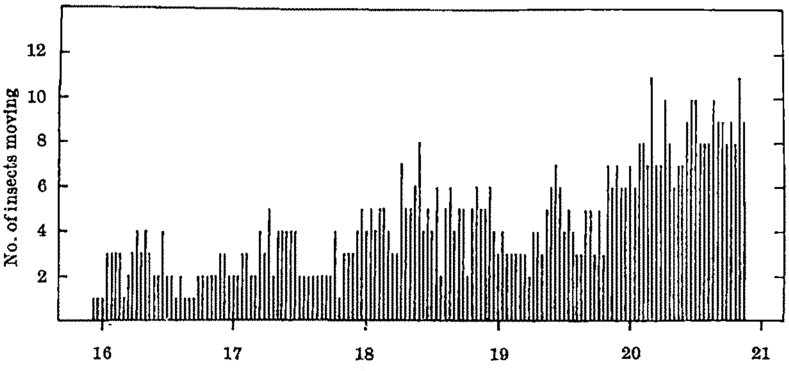

Fig. 2. Number of moving insects at 2-min. intervals over 5 hr., determined for 15 adult *D. melanogaster*, post-emergence age 24 hr., in constant illumination with water only

A plastic box (16 cm. × 7·5 cm. × 4·5 cm.) with a transparent front contains the insects. The box is mounted upright on its longer side. The sides are constructed to slope inward toward the back, thereby affording a ready view of the whole interior through the transparent front. Water, or a 15 per cent sucrose solution, is admitted through a constant-supply tube inserted through the back of the box. The insects, after being taken from the culture medium, are allowed to move along a tube into the box through a small hole at one end, which is afterwards closed. An automatic camera is mounted approximately 2 ft. from the transparent front. A clock is set beside the insect box in the camera field. With the camera diaphragm set at $f/16$ sufficient depth of field is provided for the clock and all parts of the box to be in focus. Illumination is provided by two 15-watt, 17-in. fluorescent tubes above and in front of the camera lens and a reflecting surface in the corresponding position below. Exposures of 1-sec. duration are made. Thus, insects moving during the exposure either will be blurred on the negative or, as is usually the case, will not show at all. A record is therefore obtained of the number of stationary insects during the exposure. Fig. 1 shows two sample photographs. The greater number of visible insects in the first exposure indicates the smaller amount of activity; conversely, fewer visible insects in the second exposure indicates a higher level of activity.

The frequency of exposures is determined by the nature of the experiment. In the present work at least two kinds of series are used. In one, a group of photographs (usually 12–14) is made automatically with 1-min. intervals, every 2 hr. The results from each group are averaged, and the total number of insects minus this mean is plotted against the mean time at which the photographs were taken. In a type of experiment where more rapid activity changes are expected, one exposure is made every 2 min. throughout the test period. The negatives on the long strip of 35 mm. film (25 ft. for 6½ hr.) are examined with a dissecting microscope and the number of stationary insects in each exposure is determined. Fig. 2 indicates increasing, somewhat rhythmic, activity for 15 starved adult *D. melanogaster* over a period of 5 hr. in constant illumination.

This method provides rapid and accessible records of: (1) the number of insects stationary during each exposure; (2) their positions in relation to special items, such as the food supply. Both kinds of results are readily obtained from each exposure as an individual unit without comparing adjacent pairs. Some effects on activity of varying periods of light and dark may possibly be studied with this technique by timing the light source to remain on only during the 1-sec. exposure and by varying the experimental lighting conditions. The method should prove useful in studies with other small animals besides insects. A report of the present studies of insect activity in relation to the local passage of weather systems will be presented later.

Photochemical Reduction of Blue Tetrazolium by Isolated Chloroplasts

THE use of oxidation-reduction colour indicators the solubility of which is unchanged during reduction in the Hill reaction of photosynthesis provides no information as to the site in the chloroplast in which the reaction occurs. Dyar[1] used blue tetrazolium, which is colourless and soluble in the oxidized form in water but insoluble and highly coloured when reduced, to localize regions of dehydrogenase activity in plant cells. In chloroplasts reduction was apparently confined to grana-like bodies. In some materials the reaction was dependent on light, suggesting a relation to the Hill reaction. Since non-plastid cytoplasm may have contributed to the reaction, we were interested in whether isolated chloroplasts were capable of reducing the dye.

Intact chloroplasts were isolated from red kidney beans essentially by Jagendorf and Evans's method[2]. The isolation buffer consisted of 0·3 M sucrose, 0·05 M pH 8·5 phosphate and 0·01 M potassium chloride. 5 gm. of interveinal tissue from primary leaf blades of red kidney beans were ground with 15 ml. buffer for 20 sec. in a Waring blendor, model *PH*-5, in the high-speed position. The homogenate was filtered through cheese-cloth, and the filtrate centrifuged for 3 min. at 1,000g. The resulting pellet, consisting mainly of whole chloroplasts, was made up to the original volume with pH 6·5 $M/10$ phosphate buffer. Equal volumes of the chloroplast suspension and Dyar's blue tetrazolium solution were mixed in Thunberg tubes and, after evacuation, incubated at 32° C. for 1 hr. in a water-bath, either in the dark, or illuminated at 20 cm. from a 100-W. incandescent bulb.

Reduction of the chemical, indicated by the development of a deep blue colour, was confined to grana-like structures, as in the chloroplasts in cells pictured in Dyar's article. The reaction was dependent on light, as was the staining of chloroplasts in intact mesophyll cells when small pieces of leaf were incubated with the blue tetrazolium solution.

Irradiation of chloroplast preparations 5 cm. from an *SL* 2537 'Mineralight' ultra-violet lamp (UV Products, S. Pasadena, Calif.) for 30 min. prevented development of colour.

These results extend Dyar's observations on reduction of blue tetrazolium to isolated chloroplasts, and suggest that the reaction may prove useful as a sensitive test of the structural integrity of chloroplasts during fractionation.

This work was supported in part by U.S. Public Health Service grant *E*-596*C* to one of us (M. C.).

Physiological Races of *Phytophthora infestans* Mont. (de Bary) in Northern Ireland

THE presence of several races of the blight fungus, *Phytophthora infestans*, was recorded in Northern Ireland by Doling[1]. Races commonly occurring in commercial crops were race 0 and race 4, the latter predominating. However, from hybrids of *Solanum demissum* × *Solanum tuberosum* further races were identified as follows: race 1; race 2; race 1, 2; race 1, 4; and race 1, 2, 4.

During the past season, because of suitable weather conditions (Table 1), the spread of potato blight was extremely rapid, and damage to the commercial crop was extensive. At the Plant Breeding Station, Loughgall, many seedlings which had been free of blight in previous years were attacked. These included seedlings bred from parental material carrying one or more of the four major *R* genes.

Table 1. WEATHER RECORDS, LOUGHGALL, 1958

Data	June	July	August	September
Mean maximum temperature (° F.)	62	66	64	64
Mean minimum temperature (° F.)	48	51	51	52
Mean relative humidity (per cent)	82	82	84	89
Total rainfall (in.)	4·99	5·47	3·54	3·23
No. of days with 0·01 in. or more precipitation	20	23	22	20
Total sunshine (hr.)	113·2	143·5	107·9	89·1

Plants containing the *R*1, *R*2, *R*3 or *R*4 genes singly, and in all combinations, which had been obtained from Dr. W. Black, of the Scottish Plant Breeding Station, were grown in the field and made satisfactory growth before blight appeared.

The first genotype to be attacked early in July was the one containing the *R*4 gene. Blight was next recorded by August 6, on the *R*1 *R*4 and *R*1 genotypes. By August 20 plants containing the following genes were recorded as having been attacked by the pathogen: *R*1, *R*2, *R*4, *R*1 *R*2, *R*1 *R*4, *R*2 *R*4, *R*1 *R*2 *R*4, and *R*1 *R*3 *R*4. Blight developed very slowly on the *R*1 *R*3 *R*4 genotype and plants remained green for almost three weeks after the first lesion was recorded. At this date no blight was noted on the *R*3, *R*1 *R*3, or *R*3 *R*4 genotypes, possibly as a result of differences in field resistance and/or plant development, as well as the apparently low virulence of this race (presumably race 1, 3, 4).

Blight was recorded from all genotypes, including the *R*1 *R*2 *R*3 *R*4 genotype, by September 19.

It thus appears that under suitable conditions the development of races of the pathogen may be quite rapid, and the value of the hypersensitive reaction, governed by the presence of the *R* genes, would therefore be of limited practical application.

Breeding studies now in progress[2] suggest that field resistance resulting from the presence of minor genes will be of greater value for commercial breeding. Toxopeus[3] has suggested that high resistance of foliage is not sufficient unless accompanied by a high resistance of tuber to the pathogen. This has been confirmed at Loughgall, where some seedlings showing considerable foliage resistance to the pathogen have produced badly infected tubers.

Feulgen Reaction in the Fucales

The Feulgen reaction has not been used to any great extent in cytological investigations of the larger brown algæ[1–4], possibly on account of the difficulty of obtaining consistent results. The following technique has now been applied successfully to growing vegetative apices and to developing receptacles of all the British members of the Fucales, with the exception of *Pelvetia canaliculata*, on which it has not yet been tried.

The material to be examined is cut into small pieces and fixed for 12–18 hr. in Karpechenko fluid. Fixation with acetic alcohol was also tried but often gave inconsistent results even in neighbouring cells of the same preparation. This may be due to the alcohol in the fixative causing hardening of the cell walls and thus preventing even penetration.

After fixation the material is thoroughly washed in running water. It is important at this stage to remove all traces of the fixative since it contains formalin, which gives a red coloration with Schiff's reagent[5]. If traces of the fixative are left, a red colour develops in the cell walls and in the cytoplasm and obscures the nuclear reaction.

The material is then transferred to distilled water, brought up to a temperature of 60° C. and then hydrolysed in *N* hydrochloric acid at 60° C. The time of hydrolysis varies in different species, but usually a reaction was obtained over a fairly wide range of hydrolysis times, usually of the order of 15–30 min. This maintaining of the reaction over an extended period has been correlated[5] with the presence of chromic acid in the fixative.

Hydrolysis is stopped by placing the material in cold distilled water, after which it is transferred to freshly made Schiff's reagent for 3–12 hr. After bleaching in three changes of freshly made sulphur dioxide water, hand sections are cut of the portion to be examined, mounted in sulphur dioxide water and squashed by firm pressure on the cover-slip. If permanent preparations are required, the coverslip is allowed to drop off into sulphur dioxide water and the preparation dehydrated and mounted in 'Euparal'.

In all the species examined this technique has given a good, sharp reaction. The two main drawbacks are the pigmentation of the plastids of the meristoderm and the outer cortex due to the fixative, and the fact that the technique may not macerate the material sufficiently for thorough squashing. Both these difficulties may be overcome by bleaching with hydrogen peroxide after fixation and before hydrolysis. The time of bleaching must be adjusted according to the nature of the material, delicate structures such as the receptacles of *Cystoseira granulata* requiring shorter periods than the apices of *Halidrys siliquosa*. Usually a period of 3–4 hr. in 20 per cent hydrogen peroxide has proved successful.

If bleaching has been used, then the time of hydrolysis must be considerably reduced, usually 7½–10 min. proving adequate.

This technique has been used successfully on both resting and dividing nuclei. In the former it has demonstrated a finely granular chromatin reticulum in species of *Fucus* and chromocentres in *Bifurcaria rotunda*, *Halidrys siliquosa* and *Cystoseira tamariscifolia*. All stages of division have given a sharp reaction in nuclei of both vegetative and reproductive cells.

Leaf-Enations in *Dahlia variabilis* Desf. induced by Tomato Spotted Wilt Virus

During a survey of virus-infected dahlias (*Dahlia variabilis* Desf.) in private and commercial gardens in south-west England, one diseased plant of the variety Jean was found bearing enations (Fig. 1) similar to those induced in some other solanaceous species by tobacco mosaic[1], tomato aspermy[2] and other viruses. The diseased plant was stunted and the foliage symptoms included irregular mottling and both ringspot and so-called 'oak-leaf' or chevron patterns. Oak-leaf and ringspot symptoms were occasionally present on the same leaf.

Ringspot symptoms in virus-infected dahlias have been attributed to tomato spotted wilt virus[3], dahlia ringspot virus[4] and dahlia yellow ringspot virus[4]. Oak-leaf symptoms have been attributed to dahlia oak-leaf virus[4], tomato spotted wilt virus[5] and, more recently,

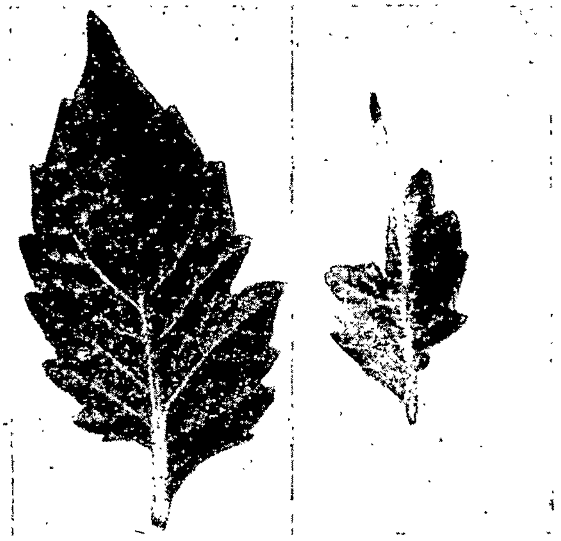

Fig. 1. Leaves of dahlia variety Jean showing enations

to a strain of cucumber mosaic virus[6]. However, experiments have shown that these enations in *Dahlia variabilis* var. Jean were induced not by a virus complex but by a strain of tomato-spotted wilt virus. When leaf extracts from the diseased plant were inoculated into a range of test plants, this virus was identified, but no other was isolated; no virus transmission to the same test plants resulted when leaf extracts were maintained at 43° C. for 10 min. before inoculation. Apterous females of the aphid *Myzus persicae* Sulz., given varying acquisition and test-feeding times, failed to transmit any virus from the diseased plant to young healthy dahlia seedlings, although in comparable experiments this species readily transmitted dahlia mosaic virus and cucumber mosaic virus from infected to healthy dahlias. When scions from the diseased plant were grafted on to the indicator variety, Willy Den Ouden, symptoms attributable to tomato spotted wilt virus were observed; when grafted to healthy plants of the same variety enations were rarely observed.

This is thought to be the first report of tomato spotted wilt virus inducing enation formation in any species of its extensive host-range, although strains of the virus have been intensively studied in relation to the pathology of tomato, tobacco and other crops.

There can be little doubt that oak-leaf, ringspot and yellow ringspot symptoms observed on dahlias in Britain and shown by these and other experiments to be induced by tomato spotted wilt virus are identical with those originally reported to be caused by separate non-sap-transmissible viruses in America[4]. Consequently, the terms dahlia oak-leaf virus[4], dahlia ringspot virus[4] and dahlia yellow ringspot virus[4] are considered to be invalid, and it is suggested that their use be discontinued.

PATHOLOGY

Effect of Neutral Red on Plaque Formation by Fowl Plague Virus

In a previous paper on the formation of plaques by fowl plague virus in Petri dishes of chick embryo cells, it was briefly reported that neutral red had the effect of reducing the number and size of the plaques formed by the virus if added to the cells at the beginning of an assay experiment, but a much smaller effect if added after three days[1].

A similar effect has been observed with poliomyelitis and western equine encephalitis viruses[2], and also with vesicular stomatitis virus[3].

A more quantitative study of this phenomenon suggests that the relation between the quantity of neutral red and the cell numbers is critical (Table 1), and also that time of reduction in plaque numbers is proportional to the concentration of neutral red (Table 2). The Rostock strain of fowl plague virus and the agar cell suspension plaque assay technique of Cooper[4] were used in all the experiments, as described in the earlier communication. Neutral red (Gurr) was used, and a standard volume was incorporated in the agar to make the final concentration in each Petri dish 1 : 10,000.

Table 1. Effect of Cell Numbers

Cells per Petri dish	Neutral red	Appearance on fourth day	Mean plaque count	Inhibition (per cent)
6×10^7	−	Plaques	71	—
6×10^7	+	Very small plaques	32	55
3×10^7	+	Toxic effect, with peripheral pallor. No plaques seen	—	—

Table 2. Effect of Varying Quantity of Neutral Red

Experiment No.	Quantity of neutral red	Mean plaque count	Reduction of plaque count (per cent)
1	Nil	61	—
	Standard	28	55
2	Nil	70	—
	Half-standard	51	27

The effect of neutral red appears early; that is, the reduction in plaque count is only slight if applied later, for example, on the third day. In this experiment (Table 3), no stain was added at the beginning, but six Petri dishes were stained on the third day and six on the fourth. All were read on the fourth day:

Table 3

Stained	Mean plaque count
Third day	22
Fourth day	26

In the experiments of Darnell *et al.*[2], the classical cell sheet technique was used, and they give reason for supposing that the neutral red acts on the infected cell, as adsorption of further virus is prevented by addition of agar overlay.

Local Inhibition by Lactation of chemically induced Breast Tumours in Mice of the *IF* Strain

THE *IF* strain of mice, established by Bonser[1], does not develop spontaneous breast tumours. However, it is very susceptible to the action of certain chemical carcinogens[2,3], developing a high incidence of tumours of the skin or breast when the chemicals are administered in an appropriate way. Dmochowski and Orr[4] showed that breast tumours so induced lacked the virus-like mammary tumour agent.

In previous studies of *IF* mice given methylcholanthrene it was found that, while the incidence of palpable breast tumours induced in virgin and forced-bred (unsuckled) mice was of the order of 70 per cent, no breast tumours were obtained in breeding mice which were allowed to suckle their young, provided the first lactation had begun before the mice received their first treatment with the carcinogen[5,6].

The experiment to be described here was performed in order to discover whether the inhibitory effect on induction of breast tumour of suckling the young was a direct local effect of lactation on the breasts concerned, or a result of the hormonal status of the lactating animals. The experiment was designed to provide breeding animals in which half the number of breasts would be suckled by young and the other half would not be suckled, though all would be subjected to the same hormonal influences. This was achieved by excising the nipples from the five breasts on one side only of 20 young adult *IF* female mice. The mice were then mated and allowed to breed freely, but the number of babies suckled was reduced to four if there were more than this number in a litter. After the first litter was born, eight fortnightly paintings of the mothers with 0·5 per cent methylcholanthrene in olive oil were begun, about 0·2 ml. being distributed over dorsal and ventral surfaces at each treatment. The mice were inspected once weekly for palpable tumours, and when these were large the animals were killed. At autopsy most of the palpable tumours were fixed and the pelts were removed and examined for non-palpable tumours. All suspicious lesions were removed for histological examination.

The mean survival of the 20 mice used from the first painting with methylcholanthrene was 28 weeks (range 19–45 weeks). The mean number of litters born after carcinogen treatment began was 3·15. Palpable breast tumours arose as subcutaneous lumps from the seventeenth week after the first painting with methylcholanthrene, many mice developing more than one. Some mice developed papillomas of the skin, and a few of these became malignant.

Table 1 shows the incidence of breast tumours in the mice. It will be seen that this was far greater in the non-lactating breasts. Only two palpable tumours were obtained on the lactating sides, whereas 31 palpable tumours were obtained on the non-lactating sides in 13 of the 20 mice. Almost all the tumours induced in this group of animals showed a very marked degree of squamous metaplasia. The two which arose on the lactating sides were entirely squamous, but it is considered that they may have arisen in breast tissue since they first appeared as subcutaneous lumps. The tumours with a marked squamous component grew more slowly than the typical adenocarcinomas with secretion which were previously induced with methylcholanthrene in virgin or forced-breeding mice of this strain. From histological study of the non-palpable nodules found in these mice, it is considered that many of the tumours probably arose from foci of squamous epitheliosis in the breast tissue, similar to those described by Pullinger[7].

Table 1. THE INCIDENCE OF TUMOURS INDUCED BY METHYLCHOLANTHRENE IN BREAST TISSUE OF 20 *IF* MICE SUCKLED ON ONE SIDE ONLY

Breast tumours	Number of mice with tumours on suckled side	Number of mice with tumours on non-suckled side
Multiple palpable	0	10
Single palpable	2	3
Non-palpable	1	2
None	17	5
Total mice	20	20
Incidence of mice with palpable tumours	2/20 = 10 per cent	13/20 = 65 per cent

The experiment described above indicates that the hormonal status of lactating animals is not responsible for inhibiting the chemical induction of breast tumours. The inhibition must, therefore, be a direct local effect of suckling on the breasts concerned. Further experiments are in progress to attempt to discover whether, or not, the inhibition by lactation results from excretion of the effective carcinogen in the milk.

I wish to thank the Birmingham Branch of the British Empire Cancer Campaign for support of this work.

Increase of Viral Hæmagglutinability of Red Cells of the Mouse after Treatment with Formalin

Clark and Nagler[1] found that the red cells of the mouse did not react very well with viral hæmagglutinin. Flick[2,3], and later on Cox and Pirtle[4], introduced the use of human red cells treated with formalin in the study of hæmagglutination by influenza virus. We found, while using formalin to stabilize the red cells of fowl and mouse for viral hæmagglutination, that the hæmagglutinability of those of the latter was considerably enhanced, particularly for certain types of influenza virus.

A slight modification of the method described by Cox and Pirtle[4] was used for preparing the preserved fowl cells and preserved mouse cells with a little modification. Mouse cells were obtained from pooled blood of a Swiss strain of mice. 100 ml. of citrated blood (with 1 per cent sodium citrate) was diluted with an equal volume of physiological saline. 40 ml. of a 50 per cent solution of isotonic formalin (20 ml. of pure formalin with 20 ml. of 1·70 per cent sodium chloride) was then added to the diluted blood. This mixture was then placed in a water-bath at 37° C.

For preparation of preserved fowl cells and preserved mouse cells like those used by Cox and Pirtle, the cells were mixed with formalin and heated twice for 2 hr. each time. Another type of cells was prepared by mixing with formalin in the same way and then heating the mixture once for 6 hr. at the same temperature. After heating, the cells were washed three or four times with about 20–30 vol. of physiological saline to remove formalin as completely as possible, and a 0·5 per cent suspension was then prepared with these cells in physiological saline for the tests provided the cells were not auto-agglutinating.

The diluted blood was treated with carbon monoxide gas before the addition of formalin to preserve the familiar red colour of the cells instead of the brown coloured cells obtained by the usual technique. This was found to facilitate the reading of the results of hæmagglutination by Fauconnier[5].

Fresh fowl and mouse cells were washed three times in physiological saline before preparing a 0·5 per cent suspension for the tests along with the preserved cells.

The strains of viruses employed in this study were egg-adapted strains of the laboratory and were used in the form of infected allantoic fluid which had been clarified by centrifuging. Salk's classical technique[6] was used for testing the hæmagglutinability of various cells. Serial two-fold dilutions in two rows starting from 1 in 2 and 1 in 3 of the virus in physiological saline were mixed with an equal volume of 0·5 per cent red cells. The reactions were always carried out at 4° C. and the results were read after 6 hr.

A typical example of the results of the hæmagglutination tests with different red cells and various virus strains is shown in Table 1.

Table 1 shows that most of the viruses included in this study exhibit a rise of the hæmagglutination titre with the mouse red cells treated with formalin as compared with the fresh mouse cells. The rise is, however, more significant with the three strains of influenza *B*. These three strains of influenza *B* seem to possess little or no hæmagglutinin for fresh mouse cells but could agglutinate the formalin-treated mouse cells to a fairly high titre which compared favourably with the titre obtained with the fresh fowl cells. Almost a similar phenomenon was also observed with a local strain (*BOS*) of mumps virus. Even with the very sensitive red cells of the fowl a slight but consistent increase in titre was found when the cells were preserved with formalin. Table 1 also shows that the period of heating of formalin–red cell mixture plays an important part, as a higher titre was usually obtained with the cells heated for 6 hr. than the titre with the cells heated for 4 hr.

Table 1. HÆMAGGLUTINATION TITRE (RECIPROCALS) WITH DIFFERENT TYPES OF RED CELLS

Strains of virus	Chicken cells			Mouse cells		
	Fresh (untreated)	Preserved		Fresh (untreated)	Preserved	
		Heated for 4 hr. (Cox)	Heated for 6 hr.		Heated for 4 hr. (Cox)	Heated for 6 hr.

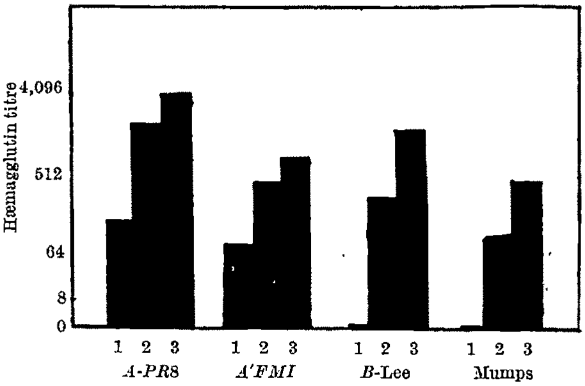

Fig. 1. Differences in hæmagglutinability of fresh and preserved mouse cells: 1, fresh mouse cells; 2, preserved mouse cells heated for 4 hr. (Cox); 3, preserved mouse cells heated for 6 hr.

It appears that formalin under certain well-defined conditions can confer the property of hæmagglutinability on certain red cells which are normally not sensitive to viral hæmagglutinin, and can enhance the same property in some normally sensitive red cells.

The mechanism of action of formalin on the red cells will have to await further investigation. It was found during this work that prolonged heating after addition of formalin to red cells brought about their auto-agglutination in physiological saline though they were found to be stable at a lower ionic concentration. Possibly the process of preparation of formalin-preserved red cells enhances their hæmagglutinability by lowering their surface charge.

This finding shows that it may be possible to demonstrate virus receptors in red cells of other species of animals after treatment with formalin which normally do not react well with viral hæmagglutinin. Similarly, hitherto undiscovered hæmagglutinating virus may also be discovered with the formalin-treated cells and attempts are now being made in this direction in this laboratory.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, March 2

British Society for the Philosophy of Science (in the Council Room, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. W. Grey Walter: "The Study of Complex Systems".

Society of Engineers (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. R. G. T. Lane: "Some Experiences of River Control in Africa".

Society of Chemical Industry (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Dr. R. A. E. Galley: "Colonial Research—Products and Pesticides" (Jubilee Memorial Lecture).

Tuesday, March 3

Society of Chemical Industry, Plastics and Polymer Group (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Dr. J. H. Green: "Aspects of Polymer Fractionation".

Royal Society of Medicine, Pathology and Radiology Sections (at 1 Wimpole Street, London, W.1), at 8 p.m.—Discussion on "Changes Produced in Tissues by Irradiation". Opening Speakers: Dr. H. J. G. Bloom, Dr. R. H. Mole and Dr. A. Glucksmann.

Wednesday, March 4

Institute of Petroleum (at 61 New Cavendish Street, London, W.1), at 5.30 p.m.—Mr. H. E. Snow, C.B.E.: "Looking Ahead. On the Threshold of Our Second Century".

Royal Meteorological Society (at 49 Cromwell Road, London, S.W.7), at 5.30 p.m.—Mr. H. H. Lamb: "Our Changing Climate, Past and Present" (Third Evening Discourse).

Prestressed Concrete Development Group (at the Royal Commonwealth Society (Craven Street entrance), London, W.C.2), at 6 p.m.—Prof. H. Rüsch (Institution of Technology, Munich): "How Can the Advantages of Prestressed Concrete Best be Utilized ?"

Society of Chemical Industry, Corrosion Group (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Meeting on "The Diagnosis of the Causes of Corrosion Failures".

Thursday, March 5

University College (in the Anatomy Theatre, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. E. Wiesenberg: "The Dead Sea Scrolls: Where do they Come From ?"

Royal Society (at Burlington House, Piccadilly, London, W.1) at 4.30 p.m.—Mr. E. M. Nicholson: "The Nature Conservancy as a Research Council".

Royal Society of Medicine, United Services Section (at 1 Wimpole Street, London, W.1), at 5 p.m.—Discussion on "Some Aspects of Naval Aviation Medicine". Opening Speakers: Surg.-Capt. F. W. Baskerville, Surg.-Lieut. P. C. Barrington, Surg.-Lieut.-Cdr. I. H. Colley and Surg.-Cdr. E. Boyd Martin.

Royal Society of Arts, Commonwealth Section (at John Adam Street, Adelphi, London, W.C.2), at 5.15 p.m.—Mr. Charles Mountford: "The Art of the Australian Aborigines and its Place in their Lives".

Institute of Refrigeration (at the Institute of Marine Engineers, The Memorial Building, 76 Mark Lane, London, E.C.3), at 5.30 p.m.—Mr. T. van Heile: "Applications of Refrigeration to Horticultural Produce in the Netherlands".

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. J. P. Pitts: "The Reliability and Life of Impregnated Paper Capacitors".

Royal Anthropological Institute (at 21 Bedford Square, London, W.C.1), at 5.30 p.m.—Mr. Peter Willmott: "Mothers and Daughters: a Discussion of Kinship in Contemporary Britain".

Institution of Mechanical Engineers, Industrial Administration and Engineering Production Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Engineering Standards—Development and Use".

Society of Instrument Technology, Data Processing Section (at Manson House, Portland Place, London, W.1), at 6 p.m.—Symposium on "The Use of Data Recorded on Industrial Plant".

Society of Chemical Industry, Microbiology Group (at 14 Belgrave Square, London, S.W.1), at 6.15 p.m.—Prof. G. F. Gause (Academy of Medical Sciences, Moscow): "The Microbe's Contribution to Cancer Research".

Polarographic Society (at "The Duke of York", 8 Dering Street, London, W.1), at 7 p.m.—Informal Discussion Meeting on "Some Polarographic Problems Encountered in Agricultural Studies" introduced by Mr. R. Peak.

Friday, March 6

Association of Applied Biologists (in the Lecture Hall of the British Museum (Natural History), Cromwell Road, London, S.W.7), at 10.45 a.m.—General Meeting. 11 a.m.—Symposium on "Recent Advances in Plant Propagation".

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 10.45 a.m.—Symposium on "Experimental Taxonomy of Vascular Plants". Speakers include Prof. D. H. Valentine, Dr. D. A. Wilkins, Dr. J. D. Lovis, Dr. S. Walker, Miss J. Buchanan, Dr. J. Savidge and Dr. V. H. Heywood.

Society for Analytical Chemistry (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Annual General Meeting, followed at 3 p.m. by the Address of the Retiring President, Dr. J. H. Hamence.

University College (in the Physiology Theatre, Gower Street, London, W.C.1), at 5.15 p.m.—Prof. J. Folch-Pi (Harvard Medical School): "Brain Lipoproteins and Proteolipids".* (First of two Special University Lectures in Biochemistry. Further lecture on March 9).

Institution of Mechanical Engineers (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Prof. J. H. Horlock: "Approximate Equations for the Properties of Superheated Steam".

Society of Dyers and Colourists, London Section (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 6 p.m.—Mr. A. E. Henshall: "The Use of Antistatic Agents in Textile Processing".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. Ronald King: "Metal Surfaces".

Saturday, March 7

Nutrition Society (at the Royal Veterinary College, Royal College Street, London, N.W.1), at 10.15 a.m.—Symposium on "Rumen Function".

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Mr. Alfred Leutscher: "Reptiles as Pets".*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant, Grade A (suitably qualified to teach mathematics to students in Preliminary, Engineering Trade Courses, and in the first year of the National Certificate Course), in the Mathematics Department—The Principal, Coventry Technical College, Butts, Coventry (March 6).

Head (with high qualifications in pharmacy and wide experience in both teaching and research) of the School of Pharmacy—The Clerk to the Governors, Chelsea College of Science and Technology, Manresa Road, London, S.W.3 (March 7).

Johns Manville Research Scholar (man or woman, with a B.Sc. honours degree or equivalent) in the Department of Chemistry, for work of a chemical and crystallographic type on silicates, especially of the chrysotile group—The Secretary, The University, Aberdeen (March 7).

Lecturer in Medical Chemistry in the Department of Medicine—The Registrar, The University, Manchester 13 (March 9).

Assistant Lecturer (preferably with some knowledge of numerical analysis) in the Department of Mathematics—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (March 11).

University Demonstrator (with an honours degree in chemistry or agricultural chemistry) in Soil Science—The Secretary, School of Agriculture, The University, Cambridge (March 11).

Assistant Lecturer, Grade B (preferably with teaching and research experience), in the Department of Physics—The Clerk to the Governors, Chelsea College of Science and Technology, Manresa Road, London, S.W.3 (March 14).

Junior Lecturer (preferably interested in physiology or in mycology) in Botany—The Registrar, Trinity College, Dublin, Ireland (March 14).

Lecturer in Zoology—The Principal, St. Anne's College, Oxford (March 14).

Lecturer or Research Assistant in Bacteriology and Virology—The Registrar, The University, Sheffield (March 14).

Lecturer (with experience in teaching physical science, preferably chemistry) in Education—The Registrar, The University, Nottingham (March 14).

Chemist (with an honours degree or equivalent in chemistry or chemical engineering, several years experience of chemical plant management, preferably in plants involving radioactive processes, and a good knowledge of the novel techniques used in the industry), to control a group of chemical plants involving the processing of radioactive materials, and to be responsible for the safe and efficient operation of these plants—The Personnel Manager, U.K.A.E.A., Industrial Group, Experimental Reactor Establishment, Dounreay, Thurso, Caithness, Scotland, quoting Ref. 2973/T (March 16).

Lecturer in Animal Ecology, or Lecturer in Plant Ecology—The Secretary, The University, 36 North Bailey, Durham (March 16).

Principal Scientific Officer (preferably 40 to 45 years of age, with wide experience in biological research and preferably also in administrative/scientific work), to take responsibility for the Conservancy's Conservation Branch in England—The Nature Conservancy (E), 19 Belgrave Square, London, S.W.1 (March 16).

Demonstrator in Physics, to assist the teaching staff in practical classes and in tutorials—The Registrar, Manchester College of Science and Technology, Manchester 1 (March 21).

Lecturer in Metallurgy—The Registrar, The University, Sheffield (March 21).

Analyst (with a degree in chemistry or biochemistry, or considerable experience in analytical chemistry) in a hospital biochemistry laboratory—The Registrar, The University, Leeds 2 (March 28).

Senior Lecturer in Nuclear Physics—The Secretary, The University, 38 North Bailey, Durham (March 28).

Assistant Lecturer in the Department of Zoology—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (March 31).

Associate Professor in Engineering at Newcastle University College, University of New South Wales, Australia—The Agent-General for New South Wales, 56 Strand, London, W.C.2 (Australia, March 31).

Junior Lecturer (with qualifications in invertebrate palæontology) in Geology—The Registrar, Trinity College, Dublin, Ireland (March 31).

Lecturer in the Chemistry of High Polymers in the Department of Textile Industries—The Registrar, The University, Leeds 2 (March 31).

Lecturer or **Assistant Lecturer** (man or woman, with an honours or special degree in statistics, or in mathematics with qualifications in statistics) **in Statistics**—The Secretary, Bedford College (University of London), Regent's Park, London, N.W.1 (April 1).

Assistant Lecturer in Zoology—The Registrar, University College, Singleton Park, Swansea (April 4).

Reader in Applied Thermodynamics at Imperial College—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 8).

Reader or **Senior Lecturer** (with a degree or higher degree in engineering of a recognized university, together with design experience in industry and teaching experience at university level in design subjects) **in Mechanical Engineering** at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, April 10).

Berkeley Bye-Fellow in the Natural Sciences or in Medicine—The Registrar, Gonville and Caius College, Cambridge (April 30).

Research Student (with a first degree in mathematics or theoretical physics, and wanting to read for a D.Phil. degree) at the Mathematical Institute, to work in electronic structure of metals under the direction of Prof. C. A. Coulson, F.R.S.—The Secretary, Mathematical Institute, The University, 10 Parks Road, Oxford (April 30).

Shell Student in Geophysics—Head of the Department of Geodesy and Geophysics, The University, Madingley Rise, Madingley Road, Cambridge (June 1).

African Pyrethrum Research Fellow (with at least a good honours degree in entomology, biochemistry or zoology), to study certain problems related to the use of Pyrethrum as an insecticide on field and horticultural crops—The Registrar, The University, Nottingham.

Computer (with experience of electronic digital machines), to join a research team studying biomolecular structure by X-ray crystallography—The Secretary, Birkbeck College (University of London), Malet Street, London, W.C.1.

Demonstrator in Crop Husbandry, and a **Demonstrator in Animal Physiology** at the School of Agriculture, Sutton Bonington—The Registrar, The University, Nottingham.

Head (graduate, preferably with both teaching and industrial experience) **of the Science Department**, Grade III—The Principal, Ewell County Technical College, Reigate Road, Ewell, Surrey.

Lecturer in Physics—The Clerk to the Governors, Northern Polytechnic, Holloway, London, N.7.

Lecturer (with appropriate academic qualifications together with a wide industrial experience in yarn manufacture, and preferably experience in teaching and/or research) **in Spinning**—The Registrar, Institute of Technology, Bradford 7.

Mining Geologist (with a first- or good second-class honours degree in geology or mining geology, or equivalent qualification) in the Federation of Nigeria, for the detailed examination and appraisal of mineral deposits including the supervision of drilling and prospecting operations—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.105/14/011.

Organic Chemist (Graduate), to join a team investigating a problem in the field of wood chemistry—The Director, Arthur D. Little Research Institute, Inveresk Gate, Musselburgh, Midlothian, Scotland.

REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

Great Britain and Ireland

National Museum of Wales. Fifty-first Annual Report 1957–58 presented by the Council to the Court of Governors on 24th October, 1958. Pp. 76+4 plates. (Cardiff: National Museum of Wales, 1958.) [1612

Society for Freedom in Science. Occasional Pamphlet No. 18: Science and the Sputniks. By John R. Baker. Pp. 6. (Oxford: Dr. John R. Baker, c/o Dept. of Zoology, University Museum, 1958.) 1*s*. [1612

Annual Report of the National Oceanographic Council, 1 April 1957—31 March 1958. Pp. v+39. (Cambridge: At the University Press, 1958.) 5*s*. net. [1612

Institution of Electrical Engineers. 1958 Amendments to the Thirteenth Edition of the Regulations for the Electrical Equipment of Buildings. Pp. 12. (London: Institution of Electrical Engineers, 1958.) [1612

Building Research Station Digest No. 116 (November 1958): Roof Drainage. Pp. 4. (London: H.M. Stationery Office, 1958.) 3*d*. [1612

Library Association Pamphlet No. 19: The Anglo-American Library Associations—an Historical Note on the Beginnings. By R. D. Macleod. Pp. 15. (London: Library Association, 1958.) 2*s*. [1612

Imperial College of Science and Technology (University of London). Fifty-first Annual Report of the Governing Body, 1957–1958. Pp. 73. (London: Imperial College of Science and Technology, 1958.) [1612

British Gelatine and Glue Research Association. Tenth Annual Report for the year October 1957 to September 1958. Pp. 16. (London: British Gelatine and Glue Research Association, 1958.) [1612

Secondary Education for All: A New Drive. Pp. 10. (Cmnd. 604.) (London: H.M. Stationery Office, 1958.) 9*d*. net. [1612

British Electrical and Allied Industries Research Association. Technical Report G/XT155: Theoretical Calculations of Arc Temperatures in Different Gases. By L. A. King. Pp. ii+9 figures. 12*s*. 6*d*. Technical Report L/T353: A Spectroscopic Investigation of Short Duration, High Current Sparks in Hydrogen. By P. Ravenhill. Pp. 12 (24 figures). 15*s*. (Leatherhead: British Electrical and Allied Industries Research Association, 1956 and 1957.) [11

Lapis: Industrial Opportunities. Issue No. 1 (October, 1958). Pp. 28. Subscription rates (including postage for one year): Inland £10. U.S.A. and Canada 30 dollars; Italy 19,000 lire; France 13,000 francs. (London: Kenneth Mason, 1 Old Burlington Street, W.1, 1958.) [11

Other Countries

United States Department of the Interior: Geological Survey Bulletin 1046–I: Geology of Majuba Hill, Pershing County, Nevada By Albert F. Trites, Jr., and Ralph H. Thurston. Pp. iii+183–203+plates 7–11. n.p. Bulletin 1058–A: Reconnaissance for Radioactive Deposits in Southeastern Alaska, 1952. By Joseph R. Houston Robert G. Bates, Robert S. Velikanke and Helmuth Wedow, Jr Pp. iv+31+3 plates. 75 cents. Bulletin 1059–E: Selected Annotated Bibliography of the Uranium Geology of Igneous and Metamorphic Rocks in the United States. By Diane Curtis. Pp. iii+205–262+plate 2. 55 cents. Bulletin 1060–A: Geology and Construction-Material Resources of Morris County, Kansas. By Melville R. Mudge, Claude Matthews and John D. Wells. Pp. iv+61+2 plates. n.p. Water-Supply Paper 1303: Compilation of Records of Surface Waters of the United States through September 1950. Part 2–A: South Atlantic Slope Basins, James River to Savannah River. Prepared under the direction of J. V. B. Wells. Pp. v+325+plate 1. n.p. Water-Supply Paper 1318: Compilation of Records of Surface Waters of the United States through September 1950.) Part 14: Pacific Slope Basins in Oregon and Lower Columbia River Basin. Prepared under the direction of J. V. B. Wells. Pp. v+550+plate 1. n.p. Water-Supply Paper 1344: Surface Water Supply of the United States 1954. Part 10: The Great Basin. Prepared under the direction of J. V. B. Wells. Pp. xi+252+1 plate. 1 dollar. Water-Supply Paper 1428: Saline-Water Resources of North Dakota. By C. J. Robinove, R. H. Langford and J. W. Brookhart. Pp. iv+72+1 plate. n.p. Publications of the Geological Survey, May 1958. Pp. vi+455. (Washington, D.C. Government Printing Office, 1958.) [1612

Commissariat a l'Énergie Atomique, 1945–1958. Pp. 66. (Paris Commissariat a l'Énergie Atomique, 1958.) [11

Proceedings of the Symposium on Phytochemistry, Kuala Lumpur December, 1957. (Sponsored by the Government of the Federation of Malaya and Unesco Science Co-operation Office for South East Asia. Pp. xii+183. (Djakarta: Unesco South East Asia Science Co-operation Office, 1958.) [11

The Turkish Journal of Pediatrics, Vol. 1, Numbers 1 and 2 (July-August, 1958.) Pp. 64. (Hacettepe, Ankara: Research Institute of Child Health, 1958.) [11

Canada: Department of Mines and Technical Surveys. Geological Survey of Canada. Memoir No. 289: Silurian Stratigraphy and Palaeontology of the Niagara Escarpment in Ontario. By Thomas E Bolton. Pp. vii+145+13 plates. 2 dollars. Memoir No. 293: Flora of the Upper Cretaceous Nanaimo Group of Vancouver Island, British Columbia. By W. A. Bell. Pp. v+84+67 plates. 4 dollars. (Ottawa: Queen's Printer, 1957.) [11

Canada: Department of Northern Affairs and National Resources. National Museum of Canada Bulletin No. 152 (Anthropological Series No. 42): Medicine-Men on the North Pacific Coast. By Marius Barbeau. Pp. v+95 (90 illustrations). (Ottawa: Queen's Printer, 1958). 1 dollar. [11

Coryndon Memorial Museum, Nairobi. Occasional Papers, No. 6: Notes on the Genus *Simopithecis*, with a Description of a New Species from Olduvai. By L. S. B. Leakey and T. Whitworth. Pp. 14+10 plates. (Nairobi: Coryndon Memorial Museum; Cambridge: Deighton Bell and Co., 1958.) 7*s*. 6*d*. [11

Annuario del Observatorio Astronómico de Madrid para 1959. Pp. 364. (Madrid: Observatorio Astronómico, 1958.) [11

Origin of Primary Extraxylary Stem Fibres in Dicotyledona. By Amélie Blyth. Pp. 145–232+plates 1–23. (University of California Publications in Botany, Vol. 30, No. 2.) (Berkeley and Los Angeles: University of California Press; London: Cambridge University Press, 1958.) 1.75 dollars. [11

Académie Royale de Belgique. Classe des Sciences. Mémoires. Tome 30, Fascicule 7: Le Spectre Electronique de la Molecule de Thiophosgène. Par Louis Burnelle. Pp. 68. (Bruxelles: Académie Royale de Belgique, 1959.) 80 francs. [11

Carnegie Institution of Washington. Report of the President. Pp. 45. (Reprinted from *Carnegie Institution of Washington Year Book* 57 for the year 1957–1958.) (Washington, D.C.: Carnegie Institution of Washington, 1958.) [11

Tables for Bivariate Osculatory Interpolation Over a Cartesian Grid. By Herbert E. Salzer and Genevieve M. Kimbro. Pp. i+40. (San Diego, Calif.: Convair-Astronautics, 1958.) [11

Rückstände von Pflanzenschutz- und Vorratsschutzmittelm von sonstigen Schädlingsbekämpfungs- und Unkrautbekämpfungsmitteln sowie von Mitteln zur Beeinflussung des Pflanzenwachtums—Literatur-Übersicht. Zusammengestellt von Oberregierungsrat Dr. H. Zeumer. (Mitteilungen aus der Biologischen Bundesanstalt für Land- und Forstwirtschaft, Berlin-Dahlem, Heft 94, Oktober 1958.) Pp. 124. (Berlin-Dahlem: Biologische Bundesanstalt für Land- und Forstwirtschaft, 1958.) [11

SP.600 SPECTROPHOTOMETER

Modern Methods

NEW METHOD SHEETS

Five new sheets have just become available:

- No. 33: *Mercury in Urine and other Biological Fluids.*
- No. 34: *Magnesium in Water and Biological Fluids.*
- No. 35: *Ascorbic Acid in Plasma.*
- No. 36: *Creatinine in Plasma and Urine.*
- No. 37: *Alumina in Fireclay and Fireclay materials.*

"Absorption measurements were carried out on the Unicam SP.600 Spectrophotometer. . . ." This phrase has appeared in the literature so many times over the last few years as to have become almost a common-place. Laboratories of all types count the SP.600 amongst their most valuable equipment, finding its simplicity of operation well suited to routine analysis, and its high accuracy and sensitivity equal to the demands of advanced research.

To help the analyst make the best use of his instrument, Unicam publish a series of Method Sheets, describing in detail a wide range of determinations carried out within the 360mμ—1000mμ range of the spectrum. Five new sheets have just become available: if you would like copies of these, or any of the earlier sheets, please write to us. They are all available free of charge.

UNICAM
SPECTROPHOTOMETERS

Strong plastic ring binders, each accepting 100 *Method Sheets, are available at* 8/6, *including postage and packing.*

UNICAM INSTRUMENTS LTD., ARBURY WORKS, CAMBRIDGE

UI 4P

LETTERS TO THE EDITORS

PHYSICAL SCIENCES

Verification of General Relativity by means of Artificial Planets.—John J. Gilvarry . . . 666

Effect of Magnetic Activity on Drifts of the *F*2 Region.—Prof. B. Ramachandra Rao, E. Bhagiratha Rao and Y. V. Ramana Murty . 667

Bose-Einstein Statistics and Helium Films.—A. D. Singh and R. K. Pathria . . . 668

Effects of Arc Stage of Electrical Discharge on Ignition of Inflammable Gas.—I. Berz; W. Nethercot and H. G. Riddlestone . . . 669

A Source of Natural Tin Whiskers.—Malcolm J. Fraser 670

Structure of Kish and Other Graphites.—Eitaro Matuyama 670

Surface Charges produced on Insulators by Short- and Long-time Ionization.—Dr. Stanley I. Reynolds 671

CHEMISTRY

Synthesis of Colour Centres in Silica and their Thermoluminescence.—J. R. Hensler . . 672

Beta-Polymorphs of Uranium and Thorium Disilicides.—A. Brown and J. J. Norreys . 673

Effect of the Carrier Gas on the Sensitivity of a Thermal-conductivity Detector in Gas Chromatography.—L. J. Schmauch and R. A. Dinerstein; Dr. N. H. Ray 673

Separation of Strontium-90 from Calcium.—P. S. Davis 674

Detection of Keto-Acids.—Dr. F. Dobinson . 675

Equilibration of *iso*Cyanates and *iso*Thiocyanates.—Prof. L. C. Case 675

Structure of Malvalic Acid and Some Related C$_{18}$ and C$_{19}$ *Cyclo*propane Fatty Acids.—Dr. B. Craven and Prof. G. A. Jeffrey . . . 676

BIOCHEMISTRY and PHYSIOLOGY

Polysaccharide Fibres in Mammalian Connective Tissue.—A. J. Cruise and J. W. Jeffery . . 677

Incorporation of Radioactive Iron into Hæmatin *a*.—Prof. R. Lemberg, F.R.S., and Miss A. Benson 678

Rate of Exchange of Phosphate in Red Blood Cells: Effect of Thyroid Hormones.—A. M. Ermans and Prof. P. A. Bastenie . . . 679

Enzymatic N-Methylation of Histamine.—Dr. Donald D. Brown, Dr. Julius Axelrod and Dr. Robert Tomchick 680

Inactivation of Isoniazid by Peroxidase.—Dr. M. O. Tirunarayanan and Dr. W. A. Vischer . . 681

Quantitative Estimation of Purines by the Visual Scanning of Photographs of Paper Chromatograms.—B. M. Johnstone and G. P. Briner . 681

Detection of Gentiobiose and Sophorose in Cultures of Certain Micro-organisms growing in Defined Glucose-containing Media.—A. W. Khan, D. N. Pellegrino and Prof. T. K. Walker 682

Malonate Metabolism by Plant Tissues.—Prof. Leland M. Shannon, Roger H. Young and Carlton Dudley 683

Micro-volume Drop-plate Assay of Antibiotics.—Dr. M. R. S. Iyengar 684

Incidence of the Erythrocytic Defect associated with Drug-Sensitivity among Oriental Subjects.—Dr. Ernest Beutler, Mary K. Y. Yeh and Thomas Necheles 684

Taurine in Human Blood Platelets.—Julian Frendo, Aleksander Koj and Jan M. Zgliczyński 685

Detection of Antigens as Specific Precipitates on Paper Electrophoresis Strips.—S. Buttery . 686

Changes in *p*H and Temperature in Poultry Breast Muscles at Slaughter.—F. E. Peters and J. W. Dodge 687

Relaxation of Glycerol-treated Muscle Fibres by Acetone.—Dr. Setsuro Ebashi and Dr. Fumiko Ebashi 687

Effect of the Rate of Elimination of Digoxigenin in the Guinea Pig on the Determination of its Lethal Dose.—M. Rand and Anne Stafford . 688

Triiodothyronine in Acute Alcoholic Intoxication.—Dr. Henry Newman and Marion Edmonds Smith 689

Adrenal Cortical Function in the Pregnant Sheep.—Kathleen W. Robinson 690

Effect of Dietary Phytate on Fæcal Absorption of Radioactive Ferric Chloride.—Dr. Henry Foy, Athena Kondi and W. H. Austin . . . 691

BIOLOGY

Radiosensitivity as a Function of Antigenic Equivocation.—Dr. L. Cohen and Dr. A. Cohen 692

Demonstration of Endogenous Pyrogen in Serum during Systemic Tuberculin Reaction in Rabbits.—Dr. J. Johanovský . . . 693

Virus-like Particles in chemically induced Carcinoma of the Uterine Cervix.—Dr. M. Thiery, Dr. M. De Groodt, Prof. F. De Rom, Prof. M. Sebruyns and Dr. A. Lagasse . . . 694

Histochemical Demonstration of A and B Antigens in Platelets.—Dr. B. D. Jankovič and K. Arsenijevič 695

*T*2 Phage Infection of 'Protoplasts' obtained by Penicillin Treatment of *Escherichia coli B*.—Dr. G. Dénes and L. Polgár 696

The Inferior Mesenteric Ganglion in Man.—J. A. Southam 697

DESIGN of LAND DRAINAGE WORKS

By R. B. THORN, B.Sc., and Associates

This is a handbook on detailed design for everyday use by both the experienced designer and the newly graduated engineer faced with his first design problems. The works dealt with are those carried out by River, Conservancy, Catchment and Drainage Boards and by similar authorities such as Irrigation and Drainage Departments.

The papers, selected from the Proceedings of the Institution of Civil Engineers, the Institution of Water Engineers and from technical journals, have been revised and where necessary brought up-to-date by the authors who are all experienced engineers of the highest standing.

Price 35*s*.

OPTICAL PROPERTIES of SEMI-CONDUCTORS

By T. S. MOSS, M.A., Ph.D.,
R.A.E., Farnborough

Dr. Moss is well-known internationally for his publications on the optical and photoelectric behaviour of semi-conductors. His present book is primarily of interest to research physicists of academic or industrial laboratories, but will also be suitable for study by honours students who are concerned with solid state physics.

The opening chapters develop the theory of the optical properties of solids, including absorption by valence band electrons, free carriers and impurities, dispersion and magneto-optical effects. The book stresses the inter-relation of the optical constants for any material, i.e., between the real and imaginary parts of the dielectric constants, the amplitude and phase of reflectivity and the refractive index and absorption constants. Up-to-date reviews of the properties of the most interesting semi-conductors are given, most of them written in late 1958, and over 600 references are provided.

Price 50*s*.

Mechanical Properties of NON-METALLIC BRITTLE MATERIALS

Editor: W. H. WALTON, B.Sc., F.Inst.P.

Proceedings of the 1958 London Conference organized by the Mining Research Establishment of the National Coal Board in consultation with the Building Research Station (D.S.I.R.).

There was a time not long ago when the properties of matter was a relatively uninteresting and uninspiring branch of classical physics but that pattern has changed quickly in recent years. With metals, and to a lesser extent with fibres and rubbers, the detailed examination of the properties of these solids by improved techniques and the development of quantitative theories to account for the properties on the basis of atomic and molecular models has transformed the subject beyond recognition. Brittle materials have lain outside these developments and have not attracted anything like the same attention, hence the necessity for holding this conference and the publication of the papers read and the discussions ensuing from them.

GRIFFIN'S STATISTICAL MONOGRAPHS & COURSES

Editor: M. G. KENDALL, Sc.D.
Professor of Statistics, University of London

This successful and extending series was first launched in 1957 and consists of volumes on specialized studies in statistics —which would otherwise appear scattered in journals or papers and on which sufficient development has not taken place to enable a mature book to be written—and of special courses on particular statistical topics.

Well produced **Accurate** **Moderately priced**

So far issued

1. **ANALYSIS of MULTIPLE TIME-SERIES.** QUENOUILLE 24/- net
2. **A COURSE in MULTIVARIATE ANALYSIS** KENDALL 22/- net
3. **FUNDAMENTALS of STATISTICAL REASONING** QUENOUILLE 24/- net

Temporarily postponed

4. **A first course in sampling** STUART

Ready Summer 1959

5. **CHARACTERISTIC FUNCTIONS** LUKACS
6. **INFINITELY MANY VARIATES** ROBINSON

Other volumes in preparation

CHARLES GRIFFIN & COMPANY LIMITED
42 DRURY LANE WC2

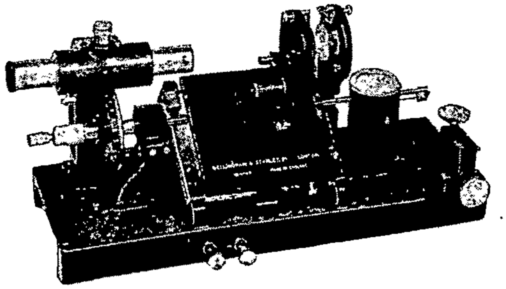
PRECISION INSTRUMENTS

Fabry-Perot Interferometer



Although of very simple design, this instrument is suitable for much of the work usually carried out by more elaborate and costly apparatus, and reads directly to 1/250 mm. It can be supplied with an attachment to convert to a Michelson interferometer, thus giving a dual purpose instrument.

Price Complete	**£190 0s.**
Attachment for converting instrument into Michelson Interferometer, extra	£45 0s.
Polished wooden case, extra	£9 10s.

EDUCATIONAL ADVANCEMENT AND THE UNDER-DEVELOPED COUNTRIES

SOME decisions taken at the Commonwealth Trade and Economic Conference which met in Montreal last September have already been discussed in these columns (see *Nature*, December 20, p. 1693). Their full significance is probably only to be appreciated in the light of the very large gap that exists between the standard of life in Asia and the standard of life in North America or Europe. The existence of that gap is, of course, well known, and was brought out by Prof. P. M. S. Blackett in his presidential address in Dublin to the British Association ; but, in pointing that out at Montreal, it was emphasized that the essential problem in Commonwealth relations is the widely different rate of economic progress between the highly industrialized and the under-developed countries, and Sir David Eccles reminded the House of Commons on November 4 that this gap is growing wider every year. That is less well known and is extremely dangerous, and it is this sense of falling further behind that disturbs the poorer nations in the free world and may induce policies that threaten their stability.

At Montreal, said Sir David, the Conference was asked what would happen if the living standards in China rose appreciably faster than the living standards in India and Pakistan. This is one of the most serious questions in the world to-day, and the Commonwealth Conference was a success because it accepted the challenge of the widening gap and devoted its best endeavours to considering how the under-developed countries could be further helped to increase their rate of progress. Even if we and other creditor countries in the free world give the under-developed countries all the aid we can, it is unlikely to suffice to finance a tolerable rate of development. This is why they need to increase their export earnings, and the Haberler report has shown that such exports must include an increasing proportion of manufactured goods.

Unless, Sir David continued, the United States and Europe buy more goods from the under-developed countries, it is hard to see how these countries can respect and adhere to the Western economic system. It is here that the real Soviet challenge lies, for once countries in Asia and Africa are bound to the Soviet block by strong economic ties, they are unlikely to remain neutral, far less align themselves with Western democracy. The practical measures concerted at Montreal were designed to meet this major issue, and they attest in particular the willingness of the United Kingdom to make the major contribution to Commonwealth development.

While the Conference recognized that development is vital not only to the economic expansion of the Commonwealth but also to the whole structure of relationships within the Commonwealth and to the maintenance of democratic institutions, the closing of this gap in standards of living was seen as a human and moral responsibility which members of the Commonwealth share with other countries. In particular, Sir David Eccles referred to the fact that no group of nations in the free world can either resist the Communist challenge from without or achieve balanced progress within its own ranks unless the United States plays a major and consistent part in maintaining economic activity and in opening its markets to the free world. We are forced back again on the interdependence of the free world as plainly as were Mr. Macmillan and President Eisenhower in their meeting during the previous autumn.

Mr. Nixon's remarks on this point in his speech at Guildhall, with its tribute to the "dedicated and effective work of the superb Colonial administrators" of the British Empire, were particularly welcome in this connexion, both as evidence of a growing understanding of the British contribution and for the reaffirmation of Mr. Nixon's deep concern to see that American foreign aid is maintained effectively in the countries which the U.S.S.R. is seeking to influence. Indeed, it is increasingly apparent that the relation of development to security is recognized, and that it is appreciated that trade and aid are important factors in a real defence policy. President Eisenhower, for example, coupled his request to Congress last year for 3,942 million dollars for the foreign aid programme with a reminder that any significant cut in this figure could lead to a massive increase in military spending by the United States, higher taxes and an increase in the rate of conscription, due to severe dislocation and impairment of the power of the free world, and the crumbling, under Sino-Soviet pressures, of United States strategic overseas positions, which might be forced back towards its own shores.

It is not, of course, only to the United States that the value of the aid programme to a country is many times greater than what it costs that country ; but in spite of what was said by the Prime Minister at the Lord Mayor's banquet and by him and Mr. Nixon at Guildhall, it will not be too easy to convince the ordinary citizen of this close connexion, and to bring home to him how important it is that assistance to the under-developed countries should be forthcoming on an adequate scale, even at the cost of some sacrifice in the standard of living in the more advanced industrialized countries. The White Paper stressed also the importance of providing the under-developed countries with opportunities to expand their trade on a stable basis, thereby increasing their export earnings and improving their prospects of attracting external capital. Neither in the House of Lords nor in the House of Commons, however, did the implications in the way of sacrifices demanded of the more industrialized countries receive much attention, though further reference to the gap was made in a debate in the House of Lords on December 18, notably in a speech by Lord Strang, who directed attention to the emphasis placed by Mr. Nehru on the grave political implications of the gap in his opening speech at the meeting of the International Bank and Monetary Fund at New Delhi.

In his speech in opening the debate on Commonwealth and international economic problems in the House of Commons on December 2, the Chancellor of the Exchequer, Mr. Heathcoat-Amory, dealt with the problem of development at some length and pointed out that the highly developed countries had expressed at Montreal a strong desire to expand the substantial help they were already giving to other Commonwealth countries. Some 70 per cent of new overseas investment in the Commonwealth since the War has come from Britain, but Mr. Heathcoat-Amory also pointed out that any country which wishes to encourage long-term private investment should make sure that conditions are favourable, and he also emphasized that the highly developed countries can only give such help if their own economies are maintained strong. Since the Montreal Conference the Government has announced, at the recent meeting of the Consultative Committee for the Colombo Plan, that the United Kingdom would make available a further £2 million for technical assistance.

All this stresses the vital importance of educational development on both sides, and Mr. Heathcoat-Amory characterized the decision on education, along with those on the improvement of telecommunications and the improvement of Commonwealth economic consultation, as the three imaginative decisions taken at Montreal. As in the House of Lords on November 4, the proposals for Commonwealth scholarships and fellowships and for an educational conference was warmly welcomed, and that their significance is appreciated appears from the stress laid by Mr. J. E. Ramsden on the teaching of English and the importance of getting more teachers of English. Sir David Eccles said, in reply, that this part would be much in mind at the conference, which would deal with the provision of teachers as well as the scheme for university students. Mr. Ramsden also referred to the importance of an adequate supply of English books, and particularly welcomed the emphasis laid in the report on training in the humanities as well as in science, stressing the relation of all the educational proposals to technical development and the value of a two-way traffic in scholars and students between the overseas countries of the Commonwealth and Great Britain.

Mr. M. MacPherson also stressed the importance of not limiting the conference on education to universities and students at an advanced level. Mr. Heathcoat-Amory had stated that already 10–12 per cent of the total places in universities and technical colleges in Britain are allotted to overseas students, two-thirds of whom come from the Commonwealth, and Mr. MacPherson suggested that it is important to get a general picture of educational needs and opportunities in the Commonwealth, so that the magnitude of the demand at the university and professional level can be assessed and the real priorities seen. What is implied in the allocation of 10–12 per cent of the places to overseas students should be known and appreciated. Mr. J. Johnson, for example, who maintained that the struggle between East and West would be determined not by arms or conflict, but by the standard of education, and that our biggest investment should be in educated people, thought that present standards in our overseas universities are much too high.

The decision as to which stage should receive priority is by no means simple. Even where the most pressing need is for primary education, the additional teachers needed involve a simultaneous effort at least in secondary education to provide them; nor can the country itself train them without expansion at the training college or university level. Indeed, it is in this interlocked situation that the contribution of the Inter-University Council for Higher Education in the Colonies has been so outstanding, and, quite apart from the continuing demand for places for overseas students in British universities and technical colleges as our own programme of expansion proceeds, the scarcity of scientific and technical manpower relates the needs of the overseas territories to those of Britain. Neither educational expansion nor technical assistance can be planned without regard to available resources in man-power, finance and equipment.

Here, therefore, as the report on the Montreal Conference sufficiently shows, educational advance overseas is related to the programme of expansion in Britain, just as much as are technical assistance and Colonial research, for example. It may well be that besides increasing economic aid to the under-developed countries, we need to find some new form of international organization to channel and co-ordinate all aid programmes. The Special United Nations Fund for Economic Development might have served, had the United States been willing to accept a plan that left the distribution of aid largely in the hands of the recipient countries themselves.

Nevertheless, the breakdown of that proposal only emphasizes a further dual aspect of the dependence of any such economic offensive on education. It is not simply that educational expansion, both in Britain and in other advanced countries, is required to provide the trained man-power of all kinds that technical aid and development demand, just as much as in the under-developed countries; it is the condition of their being able to utilize such assistance and to promote development schemes. On such educational development depends the formation of a body of public opinion and understanding in the advanced countries which will accept and sustain the programmes with all the sacrifices they entail and, in the under-developed countries, provide the climate of opinion and stability necessary both for continuity and to attract the necessary financial capital.

Nor is this any less true of the policies required to establish and maintain national food reserves in the under-developed countries set out in a recent report of the Food and Agriculture Organization*.

It is in this context that we should welcome the attention now being given in the United States to research in the tropics and particularly in Africa. Lord Hailsham's remarks to the Canada Club on November 18 are also worth noting. Canada, it may be recalled, announced at Montreal that it proposed to make 10 million dollars available as economic assistance to the West Indies over the next five years, to include provision of a second ship for the West Indies inter-island shipping service. Lord Hailsham suggested that, if the Commonwealth is to fulfil its purpose, relations must develop between the individual members of the Commonwealth on a scale almost comparable to their existing relations with Britain. Accordingly, the Commonwealth needs to think out afresh the nature and purposes of the association between its members, and the means by which that association can be enhanced.

Lord Hailsham referred to three urgent needs: to understand clearly the later development of the Commonwealth; to diversify and enrich inter-Commonwealth relations; and to foster, on a non-political level, the closest contact between individuals, business associations and professions. In particular, he stressed the need to share and think out afresh the vast task of investment and assistance in scientific research and technical education, if only to ensure that assistance is freed from any suspicion of political dependence. Finally, he emphasized the dependence of the Commonwealth on certain moral and spiritual values which are not exclusive but universal to mankind. These values are those in which science in particular flourishes and, if at this juncture technical assistance offers a particular challenge to the scientist and technologist in Britain, in the measure in which they seek to answer the challenge as indicated at Montreal they will be furthering and safeguarding the advance of science itself.

EARLY TEXTILE TECHNOLOGISTS

The Strutts and the Arkwrights, 1758–1830

A Study of the Early Factory System. By R. S. Fitton and A. P. Wadsworth. Pp. xii+361+19 plates. (Manchester: At the University Press, 1958.) 35*s*. net.

"WE must reason from what we know, and inventing is only looking at all sides of a thing and putting it in different points of view, and by long habit and a great store of ideas this becomes almost mechanical." So William Strutt, F.R.S., addressed his son, then a pupil at a Nonconformist academy, in 1818. Earlier he had expressed the hope that "in a few years you will be recommended for the R.S.". The son's felicity was obtained in other ways: he married the daughter of a bishop and was created Baron Belper in 1856. No apter tribute could have marked the centenary of the invention of the Derby rib machine by his grandfather, Jedediah Strutt.

Nonconformity had few families of such dynastic tenacity. Jedediah (1726–1797), son William (1756–1830) and grandson Edward (1801–1880) were all in their way remarkable. Jedediah, backed by dissenting hosiers at Derby and another at Nottingham, launched into manufacturing silk hose at Belper, Milford and Derby. By 1769, when he was forty-three years old, he was prosperous enough to become a backer himself. His protégé and partner, Richard Arkwright, had a roller-spinning machine, and two years later they built a factory at Cromford. This, as R. S. Fitton and A. P. Wadsworth remark in their closely documented and well-reasoned study, "was one of the turning points in the history of the factory system". It was the first of the cotton factory villages that were to change the landscape of the north of England during the next half-century. Arkwright prospered, too, and built Birkacre, near Chorley—the first to be put up outside Derbyshire—and Nottingham, Worksworth, Manchester, Matlock Bath and Bakewell, and in turn he financed Samuel Oldknow, who was manufacturing muslin. Though the Strutt – Arkwright partnership seems to have dissolved in 1781, the complex of a half-dozen factory colonies were all within a dozen miles of each other and the Strutt colonies soon outpaced the Arkwrights. Jedediah died sixteen years later and was buried in the Unitarian Chapel at Belper. His three sons, led by William, transformed the business and the cotton mills. The power of the Belper Mills was afforded by the turbulent Derwent, and a writer in "Rees' Cyclopædia" described them as "the most complete we have seen in their dams and waterworks". By 1820 fourteen acres of water had been added to the Derwent reaches just above Belper Bridge.

The water-driven machinery never stopped except for the dinner break. In these integrated factory colonies breakfast, dinner and tea were provided and, when national occasions demanded, brass bands, the players being on the pay roll. The factory colonies of the Strutts were classic examples of benevolent despotism on a small scale, and it is interesting that Samual Slater, 'founder' of the American cotton industry, served his apprenticeship with the Strutts and that William Harriman was their first customer in America. Harriman's great-great-grandson was to become ambassador to Great Britain and governor of New York.

Shrewdly the Strutts learned by others' misfortunes. After fire had destroyed one of Arkwright's mills in 1781 and the famous Albion Mills in London in 1791, they built a mill at Derby and a warehouse at Milford using iron-framed buildings paved with brick. By 1803 they were building a mill at Belper which was completely iron-framed and internally heated. Not the least of the interesting contributions which Dr. Fitton and the late Mr. Wadsworth have made to the social history of technology is their perceptive and detailed account of the way in which emergent cotton technology married up with parallel developments in other fields. Well might Ure, in his "Philosophy of Manufacturers" (1835), direct attention to their little co-operative society which had a thirteen years trial before being abandoned. Close-knit and clean, their cotton colonies were the communes of the Peak, with the Strutts as benignant taskmasters.

W. H. G. ARMYTAGE

VIRUSES, GENES AND ANTIGENS

Advances in Virus Research

Vol. 5. Edited by Kenneth M. Smith and Max A. Lauffer. Pp. ix+376. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1958.) 9.50 dollars.

PROBABLY what most people first want to know about a collection of review articles is: Who is writing and what about? This is easily answered: J. B. Brooksby on "The Virus of Foot-and-Mouth Disease"; Herbert A. Wenner on "Psittacosis-Lymphogranuloma Group of Viruses"; Gunther S. Stent on "Mating and Reproduction of Bacterial Viruses"; G. Bertani on "Lysogeny"; Ph. L'Héritier on "The Hereditary Virus of Drosophila"; Forest Fulton on "The Measurement of Complement Fixation by Viruses"; Anne Buzzell and Martin Hanig on "The Mechanism of Hemagglutination by Influenza Virus"; but to comment usefully on this collection in a brief notice is more difficult. From the many facts and much speculation, what perhaps emerges most obviously is how disparate is knowledge about different groups of viruses and how varied are the techniques and types of approach to their study.

The first two articles are primarily concerned with viruses as pathogens, summarizing general properties, host ranges and the like. Information on the constitution of members of the Psittacosis group is much needed, for these are exceptional in that some diseases they cause are amenable to chemotherapy, suggesting they may be chemically more complex than smaller viruses. The next three articles are concerned with pathogenicity only as an experimental tool. The two on bacteriophages are excursions into radiobiology, genetics, the replication of nucleic acid, and the relationships between nucleic acid and protein synthesis, subjects for which these systems provide elegant experimental material and results rich in their scope for speculation. The juxtaposition of the article on the *Drosophila* virus and lysogeny stresses the similarities between the two systems and makes almost irresistible the temptation to extrapolate from the knowledge about bacteriophages to the constitution of the *Drosophila* virus about which nothing is known. That this virus was for long accepted as an example of cytoplasmic inheritance vividly illustrates how difficult it can be to define the boundaries between genetics and pathology.

The last two articles are not at all concerned with viruses as pathogens, but with other properties useful in assays. Fulton's scholarly analysis of the complement fixation test would be equally, perhaps more, appropriate to a volume on serology. However, there was no need to justify its inclusion for such questionable reasons as that viruses can rarely be obtained concentrated enough to use other serological methods and that virus workers are prejudiced against complement fixation. The precipitin test is used successfully with many viruses, and complement fixation is mentioned too often in the first two articles in this volume to suggest any strong prejudice against it. A third reason he offers is that "the complement test is both easier and more specific than hemagglutination techniques", the subject of the last article. Fulton says "Hemagglutination is bedevilled by non-specific inhibitors, and is a much more sophisticated technique than it first appears". In this, Buzzell and Hanig seem to agree, for they say "the ostensible simplicity of the hemagglutination reaction is, in reality, confused by a mass of diverse, and often contradictory evidence. Any mechanism which might be proposed to explain these divergences must be exceedingly flexible and endowed with so many parameters that it may be expected to explain anything". A cynic might be tempted to add that this is also true of mechanisms proposed for some other phenomena described in this volume.

Probably few virus workers will read all these articles with interest, but even fewer will find nothing of interest. The authors deserve credit for discussing their subjects critically and not simply summarizing all published work. It is less praiseworthy that reading is often unnecessarily tedious because some have rarely used one word when they could employ three.

F. C. BAWDEN

CHEMISTRY OF THE STEROIDS

Chemistry of the Steroids

By Prof. Charles W. Shoppee. (Organic Chemistry Monographs.) Pp. vii+314. (London: Butterworths Scientific Publications; New York: Academic Press, Inc., 1958.) 50*s.*; 9 dollars.

FROM the author's preface it would appear that this volume has been written with the object of providing both a concise account of our present knowledge of the chemistry of the steroids and a more complete one of recent work, particularly when this has appeared since existing treatises on the subject were compiled. It is thus apparently intended to serve the dual purpose of a text-book and a work of reference. In the latter capacity it will prove invaluable, for it summarizes most of, if not all, the reactions which the individual steroids undergo and is liberally provided with references to the original sources. As a text-book it also contains many valuable features. It is useful to have collected together in one volume the principal data on which the accepted structures, conformations and configurations of the individual steroids are based; it is advantageous to possess brief summaries, translated in terms of present-day notation, of the fundamental contributions made by Windaus and Wieland to our knowledge of the structures of the sterols and bile acids; and it is convenient to have available outlines of the methods by which so many partial or total syntheses of important steroids have been effected. But its value as a text-book is somewhat diminished by the interspersing throughout the text of long passages—no doubt necessary in its capacity as a reference book—which consist of catalogues of chemical reactions. These make monotonous reading and destroy the continuity of the subject-matter.

As the title indicates, the book deals solely with the chemistry of the steroids. Nevertheless, brief statements of the functions or physiological activities of the individual compounds or groups are, when known, necessarily made. The subject-matter has been clearly and, so far as I can ascertain, accurately presented. Attention may, however, be directed to the following minor points:

The statement in the introductory chapter that the steroids are, "for the most part, saturated natural products . . ." appears to be misleading. For, while it is true that the bile acids follow this 'rule', the sterols, steroid hormones and other steroids do not.

In the chapter describing the sterols, each individual sterol is described in a separate section. Coprosterol (coprostanol) is not so treated, although it is mentioned elsewhere incidentally in the text. As a naturally occurring sterol, coprosterol should surely have been accorded individual treatment.

The occurrence of ergosterol in ergot, from which fact it derives its name, might have been mentioned. It is true that it also occurs in yeast, which now constitutes its chief source.

Finally, it seems a pity that a chapter has not been devoted to the steroid alkaloids, particularly as individual members of this group are occasionally mentioned in the text. E. STEDMAN

POLYMER CHEMISTRY

The Kinetics of Vinyl Polymerization by Radical Mechanisms

By Dr. C. H. Bamford, Dr. W. G. Barb, Dr. A. D. Jenkins and Dr. P. F. Onyon. Pp. xii+318. (London: Butterworths Scientific Publications; New York: Academic Press, Inc., 1958.) 50*s*.; 8.80 dollars.

The Effects of Ionizing Radiation on Natural and Synthetic High Polymers

By Frank A. Bovey. (Polymer Reviews, Vol. 1.) Pp. xiii+287. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1958.) 8 dollars.

Physical Chemistry of High Polymers

By Dr. Maurice L. Huggins. Pp. 175. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1958.) 52*s*. net.

THE mechanism of vinyl polymerization has probably been studied in more detail than that of any other kind of chemical reaction, and in this book Dr. Bamford and his co-authors have presented a unified and thorough treatment of this important subject.

The two first chapters discuss the broad theoretical concepts upon which the subject rests, and the following four chapters summarize critically the experimental data for most of the important monomers and the relation of these results to the general theoretical developments. The chapter on heterogeneous polymerization—which refers only to those polymerizations in which the propagating radicals pass from one phase to another—is an original treatment based largely on the authors' own studies, and is particularly valuable since this subject is rarely dealt with in the standard works on polymer kinetics. The final chapter treats the statistical aspects of vinyl polymerizations and in particular the calculation of molecular weight distributions. This book is the most complete and up-to-date survey of the subject the reviewer has seen and it can be highly recommended to students and others interested in the synthesis of high polymers and to those chemists with wider interests in the mechanism of free radical reactions.

The book by Dr. Bovey is the first of a new series of "Polymer Reviews" (edited by Prof. H. Mark) in which emphasis will be placed on the principles and state of knowledge of newer developments in polymer chemistry, and it has set a very high standard. Although the importance of a study of the effects of radiation on dead and living matter has been recognized since the discovery of X-rays (1895) and radioactivity (1896), the greatest stimulus to the present-day intensive study of the subject has been the development of nuclear reactors and the application of high-intensity radiations. The consequent need to understand the effects of these radiations over long periods of time both on ordinary materials of construction and on living cells is obvious. In the use and application of high polymers it is clearly necessary to have a clear understanding of the mechanism of the beneficial aspects of radiation such as the improvement in mechanical properties of some plastics by cross-linking and also the scientific information which will permit the development of polymers which resist the effects of radiation. More important still may be the understanding of the effects of radiation on the polymeric material which constitutes cells and other living organisms.

This book is timely in that it reviews in a critical manner the basic results so far obtained in the study of the irradiation of high polymers. The opening chapters summarize the general properties and chemical effects of radiation and the radiation chemistry of high polymers in particular. The remaining chapters deal with the various synthetic and natural polymers in detail. The book as a whole is a thorough, critical and reliable review of this growing subject. It is a most stimulating account of the theoretical and practical aspects of what has rapidly become an important branch of polymer science.

Dr. Huggins's book is based on a course of lectures he delivered in Japanese universities and emphasizes his own important and fundamental contributions to chemistry. The book as a consequence is uneven in character. Brief reference only is made to many of the important aspects of polymer synthesis and properties whereas the valuable theoretical work of the author on the thermodynamic properties of solutions is described in detail. Other interesting chapters are those on dynamic properties of polymers and their solutions and on the general aspects of the structures of natural and synthetic high polymers. The author presents many original points of view and in this sense the book is of value to the specialist. Although covering the whole physical chemistry of polymers, the book is too condensed to be of great value to the student seeking a basic introduction to the subject. C. E. H. BAWN

MICROBES AND MILK

Dairy Microbiology

By Prof. Edwin M. Foster, Prof. F. Eugene Nelson, Prof. Marvin L. Speck, Prof. Raymond N. Doetsch, and Prof. Joseph C. Olson, Jr. Pp. xvi+492. (London: Macmillan and Co., Ltd., 1958.) 42*s*. net.

THE authors of this book are all professors or associate professors of bacteriology or dairy bacteriology in teaching institutions in the United States; this strengthens the impression, while not motivating it, that "Dairy Microbiology" is in several ways tailored to the American system of education. It is a form of students' text-book, though, as the authors hope, it should have considerable appeal in other fields, particularly technology, largely as a ready-reference book. Broadly, the first six chapters deal with the general application of microbiology to dairying, and the remaining nine with the microbiology of specific dairy products, waste disposal and the utilization of by-products. With the exception of some of the illustrations, which are lacking in clarity and definition, the quality of reproduction is admirable.

"Dairy Microbiology" is indeed a veritable omnibus and very little material that is cognate has been overlooked, but its comprehensiveness seems sometimes to have been achieved at the expense of attention to detail. The need of the student to assimilate facts while only currently developing his critical faculties evokes the responsibility of authors to present him with something approaching the bare minimum consistent with accuracy and completeness. In some places detail is lacking, while other sections of "Dairy Microbiology" are rather overloaded with data. The style and presentation of material are frequently naïve and elementary though admirably clear and straightforward, but at times assume considerable erudition on the part of the reader in disciplines other than microbiology. Despite irritating mixtures of passive and imperative tenses in descriptions of techniques, there are few inaccuracies and inconsistencies and the book cannot be criticized on matters of fact. References, with titles, are a welcome feature, even be there few to publications appearing after 1954, the book having been published in the United States late in 1957.

The subject-matter is not confined to American practice, but systems and techniques foreign to the United States receive in most cases scant mention ; there is, however, one outstanding instance where this is not so—the excellent and all-embracing chapter on the microbiology of cheese. Even here, though, the mechanization of Cheddar cheese manufacture is not covered, perhaps because of its so recent inception. There are, too, other important developments in dairy microbiology that are not mentioned, probably for the same reason, which, however good in itself, must still have the effect of dating the book : they include immersion cleaning as such, and calcium-free bacteriophage-resistant media for the propagation of starter cultures.

Perhaps the most disappointing feature of "Dairy Microbiology" is its homogeneity. Too many cooks usually spoil the broth, one imagines, by the addition of too many conflicting ingredients. In this instance, however, the authors have failed to inject into it any flavour of their own particular views or opinions, or indeed any strong flavour at all. This is particularly unfortunate since the list of individuals is indeed impressive, and many of their views are known to be both enlightened and stimulating. Although lacking any form of philosophy or impact, and leaving no profound impression other than of enormous compilation, "Dairy Microbiology" is, in that latter capacity, excellent value at so modest a price.

C. A. E. BRIGGS

APPARATUS AND APPLICATIONS OF MASS SPECTROSCOPY

Mass Spectroscopy

By Prof. Henry E. Duckworth. (Cambridge Monographs on Physics.) Pp. xvi+206. (Cambridge: At the University Press, 1958.) 35*s*. net.

THE branch of physics christened mass spectroscopy by Aston has experienced a remarkable growth. The types of instruments for ion analysis have increased in number and in performance, while their applications have extended into astronomy, biology, chemistry, engineering, geology and branches of physics other than nuclear. Prof. H. E. Duckworth has written a very concise account of the principles of positive-ion optics, the generation and detection of positive ions, and of spectrometers of all kinds used in the analysis of ions. The second half of the book summarizes the application of mass spectroscopy in physics, chemical physics and geophysics. In addition, there is briefer mention of other uses, such as gas analysis, stable isotopic tracer work and various applications in chemistry. The book concludes with a table of isotopic abundances and masses determined by mass spectrometric methods. The mass values for A less than 40 were measured by Nier and his collaborators, while greater mass values were based on the author's own research work.

The book is remarkably free from errors of a scientific kind, but some appear. Prof. Duckworth, in discussing spectrometers which provide first-order double-focusing for all masses plus second-order direction-focusing for one mass, specifically omits the common Mattauch and Herzog design of spectrometer which has the second-order focusing feature. Although some of the advantages of the vibrating-reed electrometer are specified, a most important advantage, the fact that there is no grid current, dependent on voltage, in parallel with the input current, is omitted. In discussing direction-focusing mass spectrometers with sector fields the statement is made that the resolution is independent of the angle of deflexion. This independence obtains only for symmetrical instruments. On p. 131 the (^{6}Li + n) reaction products are given incorrectly.

Almost every section of every chapter of Prof. Duckworth's monograph attributes the first study or first use of something to one or another person, and these assignments are in the main the same as those which have appeared in earlier books. There are, however, oversights and errors which might be corrected. For example (p. 13), the focusing properties of sector fields and Barber's rule were clearly illustrated by Aston in 1919. Aston (1919) also suggested focusing by a spherical condenser before Brüche and Henneberg (1935). Although Smythe, Rumbaugh and West (1934) first devised the general formula for obtaining higher-order direction-focusing in homogeneous magnetic fields, they are not mentioned in section 2·6. The emission of positive ions from heated salts and hot filaments is generally attributed to Gehrcke and Reichenheim (1906, 1907) as in section 3.2, but J. J. Thomson (1899) credits Elster and Geitel (1889) with the discovery that positive ions were emitted from hot filaments. C. J. Davisson (1912) credits the discovery of emission of positive electricity from heated salts to J. C. Beattie (1899). O. W. Richardson (1908, 1910) and his students, Hulbirt and Davisson (1912), carried out the first definitive research on identifying positive ions from hot salts and hot filaments. They thus clarified a difficult existing situation in which thermal ionization of residual gas atoms had been held responsible for the currents observed from uncoated filaments. This work, which antedated that of Dempster, is not mentioned.

Prof. Duckworth has written a concise but comprehensive book on mass spectroscopy which should prove valuable to anyone engaged in the analysis of ions. The large reference bibliography with individual page references to the text, and the index, both of which were obviously prepared with great care, enhance the value of the book.

K. T. BAINBRIDGE

Administrative Medicine

Transactions of the Fifth Conference, October 29, 30, and 31, 1956, Princeton, N.J. Edited by George S. Stevenson. Pp. 197. (New York: Josiah Macy, Jr., Foundation, 1958.) 3.75 dollars.

THE Josiah Macy, Jr., Foundation has organized more than twenty conference groups of experts in different fields during the past fifteen years, each group meeting for a few days annually over a period of five years or more. Discussions, limited to twenty-five participants, are quite informal; one member introduces a topic and is subjected to frequent interruptions by way of questions or comment. Discussions are reported verbatim in the Transactions and the interruptions too often distract the reader's attention from the main issue. There are no formal conclusions and no recommendations are made. Three topics are presented in this volume: "Mental Health Elements in Administration of General Health", by Dr. Paul V. Lemkau; "The Administrative Role in the Management of a Mental Hospital", by Dr. Alfred P. Bay; and "Co-ordination of Local Resources: Techniques and Devices for Communication and Cross-fertilization", by Dr. T. P. Rees. Discussion on all three subjects dealt mainly with the means of integrating problems of mental health with other organized medical services and securing the active co-operation of the community in this integration. This appears to be a more difficult task in the United States than in Great Britain and the description by Dr. Rees of his 'open door' policy at Warlingham Park Hospital and his organized mental health service in Croydon aroused great interest. The selection, training and qualifications of hospital superintendents were also discussed, particularly in relation to geographically isolated hospitals, hospitals closely integrated with the community and hospitals of different sizes and types. G. A. CLARK

Amphetamine Psychosis

By P. H. Connell. (Maudsley Monographs, No. 5.) Pp. 133. (London: Chapman and Hall, Ltd., 1958. Published for the Institute of Psychiatry.) 21*s.* net.

CONSIDERING the number of years that the amphetamines have been available on the market and the wide range of their therapeutic usefulness, addiction to these drugs had always been regarded as rare and limited to psychopathic personalities who might have become addicted to anything. This latest Maudsley Monograph is calculated to shake the complacency of pharmacologists, psychiatrists, medical practitioners and manufacturers, and is therefore deserving of careful study. Dr. P. H. Connell, in a study of the literature, has found only six authenticated cases of amphetamine psychosis from Britain in the past twenty years, but he goes on to report another forty-two cases, of which twenty-eight were seen by him personally and the rest were discovered by inquiry among his colleagues. He emphasizes the remarkably close resemblance between the mental symptoms of amphetamine addicts and of those with paranoid schizophrenia, and points out that a single large dose of the drug may cause psychotic symptoms. The author's tabulation of the findings in the various cases is interesting and revealing, particularly when he touches on the relationship between the psychosis and the previous personality of the patient. Unfortunately, certain parts of this book must have been written some time ago, for we are told that no fewer than seventeen patients obtained their drug supply from the contents of amphetamine inhalers. An addendum mentions that amphetamine inhalers have been withdrawn from the market.

The second part of the monograph deals with the search for, and validation and use of, a biochemical test for detecting that a patient has been taking amphetamine. There is a bibliography occupying two and a half pages. W. R. BETT

Bibliography on the Effects of Ionizing Radiations on Plants, 1896–1955

By Arnold H. Sparrow, John P. Binnington and Virginia Pond. Pp. v+222. (Upton, New York: Brookhaven National Laboratory, 1958. Obtainable from Office of Technical Services, Department of Commerce, Washington, D.C.) 2.25 dollars.

THIS list of nearly 2,600 titles is arranged alphabetically by first authors with cross-references to include others. The articles are from 496 journals, 54 of them originating in the U.S.S.R. or countries of the Eastern bloc, as well as a number of books, symposium reports, etc. There is an excellent subject index occupying 90 pages. The volume is paper bound, but printing is clear and uncrowded on heavy paper.

The usefulness of this publication will be obvious to all who have experienced the difficulty of tracking down papers dealing with the biological effects of radiation in the large number of journals through which they are scattered. Although the list may not be complete, its coverage is comprehensive enough to make it invaluable to research workers in many phases of radiation biology, botany and agriculture. It is unfortunate that at the time of release it is nearly three years out of date: a supplementary list would already be useful and will soon, in this fast-moving field, be overdue. One hopes that the success of this publication will encourage the authors to prepare a second before very long.

ALMA HOWARD

Nuclear Scattering

By K. B. Mather and Dr. P. Swan. (Cambridge Monographs on Physics.) Pp. ix+469. (Cambridge: At the University Press, 1958.) 80*s.* net.

THE authors set out to describe the physics of nuclear scattering in a volume of 469 pages, the early chapters of which provide an introduction to the relation of nuclear scattering to nuclear forces and to the kind of apparatus which is used. The main body of the book is devoted to nucleon – nucleon scattering at both low and high energies, nuclear scattering and nuclear models and resonance. In this field, in which there is so much current literature, it is not possible within the confines of a single volume to be exhaustive and up to date at the instant of publication. However, the authors do present significant results available in mid-1957 and their interpretation in terms of nuclear forces and structure. At a few places the description of apparatus appears to be too detailed. Nevertheless, the selection from the information available has been carefully made. Although to an expert in any particular aspect of nuclear scattering, the treatment may appear rather sketchy, the book as a whole is a balanced representation. For this reason it will be welcomed by experimentalists and should provide valuable reading for the graduate student starting research as well as for those already actively engaged in this field.

THE ROYAL GREENWICH OBSERVATORY

By DR. R. v. d. R. WOOLLEY, F.R.S.
Astronomer Royal

THE Yapp 36-in. reflecting telescope of the Royal Greenwich Observatory was brought into operation in September 1958. The move of the instruments from Greenwich to Herstmonceux is now therefore completed, and the Observatory can now look forward to an active observing programme with the equatorial telescopes, as well as with the meridian instruments.

There are six domes in the Equatorial Group at Herstmonceux, which contain instruments as follows. Dome *A* houses the 30-in. reflector. This telescope was formerly placed on the same mounting as a refractor, but they have now been provided with independent mountings. The telescope is available for spectroscopic or photoelectric work, and it is proposed to use it to test image-converter tubes, if these become available. The primary mirror was re-figured, but in the meantime it has been found that the secondary mirror is imperfect, and this is also being re-figured.

Dome *B* houses the Yapp 36-in. reflector. This is a comparatively modern instrument, for it was built by Grubb Parsons in 1934. It is equipped with a prism spectrograph, which is now being used to determine radial velocities of stars of special dynamical interest. It is, however, proposed to replace this prism spectrograph with a fast modern grating spectrograph, to be constructed in the Observatory's workshops.

Dome *C* at present contains the Isaac Roberts 20-in. reflector, on loan from the Science Museum, South Kensington. This small telescope is very valuable for photoelectric work, but as it is required by the Museum it will be replaced by a Schmidt reflecting telescope, for which, in fact, this dome was originally provided. It is proposed to equip the Schmidt telescope, which will have a long focal ratio, with objective prisms including Fehrenbach's double prism, with which radial velocities can be determined.

Dome *D* houses the astrographic telescope. This telescope is particularly valuable on account of the existence of old plates (some with epochs as old as 1885) taken with this and similar instruments from which proper motions can be derived by comparison between new and old plates. A programme of proper motions of stars, particularly those with special dynamical significance, is in hand. This telescope also carries the Markowitz moon camera, which is used at the time of full moon.

Dome *E* houses the Thompson 26-in. refractor. This is the telescope with which the Greenwich determinations of stellar parallax have been made. It is not generally realized that determinations of trigonometrical parallax are not really in a satisfactory state, and since so much astronomical reasoning depends ultimately on trigonometrical parallaxes, further programmes of parallax determination are of the greatest importance. It is to this work that this

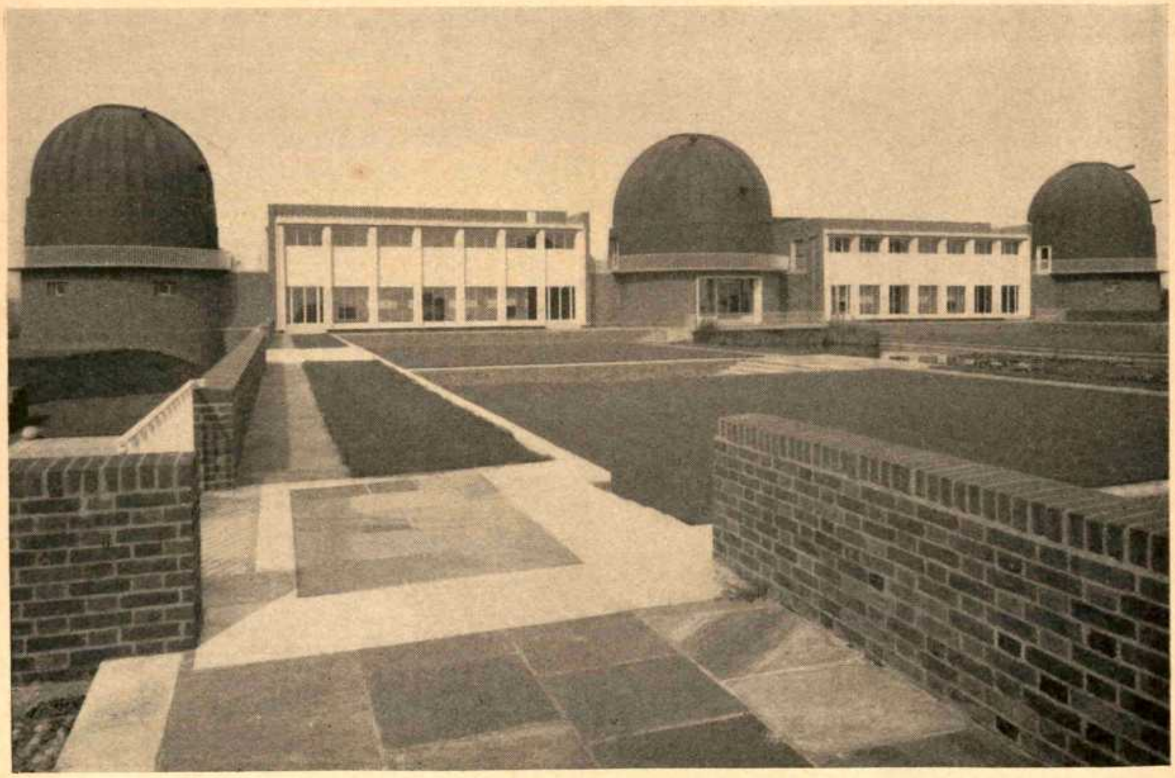

Fig. 1. The Equatorial Group at Herstmonceux

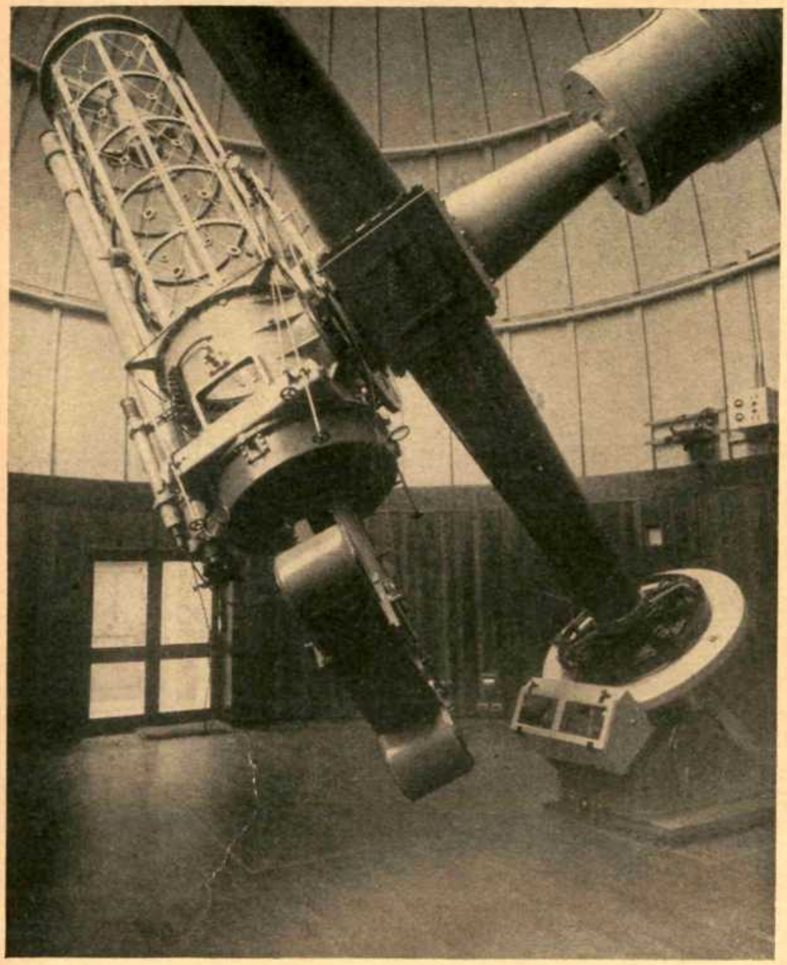

Fig. 2. The 36-in. Yapp Telescope

telescope will be mainly devoted. The dome is equipped with a rising floor.

Dome *F* contains the old 28-in. refractor. The polar axis of this telescope is in the form of an open hexagonal cage. It was designed by G. B. Airy and is a larger edition of a wooden cage which he built for the Northumberland equatorial in Cambridge. The ironwork of the 28-in. cage is one hundred years old almost exactly, but the telescope is not so old. It is larger than the original telescope and was put in the old cage at Greenwich from motives of economy. At Greenwich it could not point at the zenith because the eyepiece struck the floor as the zenith was approached. It is mounted higher at Herstmonceux and the telescope can now point at the zenith with a couple of feet to spare. It will be used for observations of visual double stars. These observations are extremely important for the determination of stellar mass. While double-star observing was prosecuted vigorously—or perhaps even overdone—at the end of the past century, not nearly enough attention is paid to the subject with large telescopes in the present decade, with the result that information which will be needed for the orbits, most of which are of long period, is not being secured.

The principal meridian instrument of the Observatory is now the Cooke Reversible Transit Circle. This instrument was constructed in 1933 and, had it not been for the Second World War, would have taken over from the famous Airy Transit Circle at Greenwich. However, detailed investigation of the instrument delayed its use on a full programme. The Airy Transit Circle remained in use until the Meridian Department moved to Herstmonceux.

Advantage has been taken of the interruption in the meridian work to introduce two major modifications to the Cooke instrument. The contact times from the transit micrometer are now recorded directly on punched cards by means of an apparatus known as *Epic* (electronic punch indicating chronograph), which has been designed and constructed in the Electronics Laboratory of the Observatory, and the visual circle-reading microscopes have been replaced by cameras. The films from the latter are measured on a screw measuring machine fitted with a digitizer, the output of which is recorded directly on punched cards. Thus, the observational data in each co-ordinate are obtained in a form most suited to automatic reduction.

The first major programme with this instrument was commenced in October 1957. This is part of the large international project for meridian observations of reference stars for the third Katalog der Astronomischen Gesellschaft, the new photographic catalogue. When compared with the second Katalog der Astronomischen Gesellschaft, this new catalogue will yield proper motions of some 200,000 stars. Twelve observatories are co-operating in this meridian programme. The Royal Greenwich Observatory has undertaken to make about 70,000 observations, including observations of reference stars, FK_3 and FK_3 Supplement stars, stars in the zones of the photographic zenith tubes, and a list of *O* and *B* type stars the proper motions of which are required for galactic research. More than 20,000 observations have been made during the first twelve months of the programme.

The Photographic Zenith Tube (P.Z.T.) was brought into operation during the latter part of 1955. The first two years observations have been analysed to give corrections to the assumed right ascensions and declinations of the stars in the 0·5°-wide zone centred on the Herstmonceux zenith.

Since the beginning of 1958, the time and latitude results have been sent regularly to the Bureau International de l'Heure in Paris, and the office of the International Latitude Service in Turin. The latitude observations are incorporated in the Service International Rapide, which was set up on the recommendation of the Dublin meeting of the International Astronomical Union in 1955 to publish co-ordinates of the pole with the minimum of delay, for use in the various national time services.

The time observations are used in the Observatory time service, and the latitude observations will be used in due course for correcting the declinations observed with the transit circle for the effect of latitude variation.

In addition to the regular determination of clock error and latitude, observations extending over a long period can be used for deriving a correction to the adopted constant of nutation.

The other new buildings at Herstmonceux house the workshop, chronometer repair shops, the Time Department with its quartz clocks, and the Nautical Almanac Office. These premises were occupied in various stages during the past year, and the move from the old huts, in which some of the departments were temporarily located, is complete. (The Time Department moved from Abinger.) The huts, which were put up in front of the Castle to provide accommodation for an insurance company that was evacuated to Herstmonceux Castle during the War, have been removed and the ground grassed over.

The control of the national time service, which had been maintained from the war-time emergency station at Abinger Common, near Dorking, was transferred to Herstmonceux during 1957. The centre block of the new West Building contains the clock cellars in the sub-basement, and the clock room, control room and battery room in the basement.

With the opportunities afforded by the transfer to new permanent premises, much care and attention were devoted to the layout, and experience so far has shown the general arrangements to be sufficiently flexible to permit modifications and development.

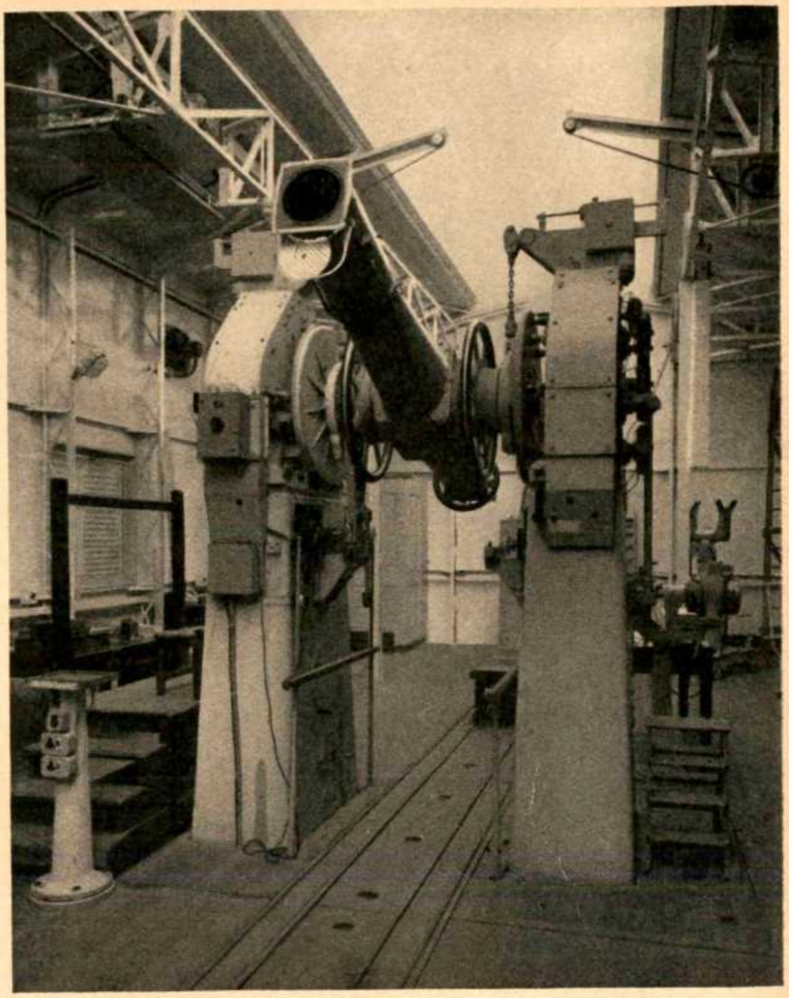

Fig. 3. The Cooke Reversible Transit Circle

The quartz clocks employ ring crystals transferred from Abinger and running in oscillators designed and made in the Electronics Laboratory. The control room equipment follows the general pattern of the Abinger installation; the decimal counter chronometers have been replaced by similar instruments of newer design; new radio receivers by Plessey and Racal have been installed in place of the war-time American receivers; in addition to single aerials on the roof of the building, a Wells array has been provided for the reception of nearby short-wave transmissions and an inclined-V array for reception of radio time signals from greater distances. A visual display unit has proved of particular value in facilitating accurate measurements on signals which have suffered distortion or which are subject to variable fading.

By means of a land-line link two standard clocks, one at the National Physical Laboratory and the other at the Post Office Laboratories, Dollis Hill, operate continuously running comparison meters at the Observatory. At any time the best clocks at the three stations may be used, in conjunction with the Photographic Zenith Tube observations, for the establishment of Greenwich Mean Time. The link with the National Physical Laboratory is of particular interest, since this permits comparison of the clocks with the cæsium standard.

Rhythmic radio time-signals, which have been controlled by the Royal Greenwich Observatory since 1927, are now regarded as obsolete and were discontinued in 1958. The 'English' type of signal, introduced by the Observatory in 1950 and still radiated twice daily, has now been generally adopted as a convenient standard. Arrangements are now in hand for the installation of control equipment at the transmitting station instead of at the Observatory, thus eliminating errors due to variations in the time of travel of the signal along the land lines.

Because of the irregularities inherent in a time-scale based on the rotation of the Earth on its axis, astronomers have adopted a new standard based on the annual period of the revolution of the Earth in its orbit around the Sun. Time determinations on the new scale are, for technical reasons, related to the motion of the Moon as observed against the background of the stars. A special Moon camera has been installed, and the Observatory has undertaken to measure plates taken at Perth, Canberra, Wellington and Naini Tal in addition to those taken at Herstmonceux.

H.M. Nautical Almanac Office has now been installed in its new offices in the West Building for more than a year. Its work largely consists of the compilation and publication of the ephemerides and almanacs required by astronomers, navigators and surveyors. In recent years there has been introduced a policy of unification of its publications with those of the Nautical Almanac Office of the U.S. Naval Observatory; for the year 1960 the astronomical ephemeris (until 1959 published under the title of "The Nautical Almanac") will be completely unified with the corresponding American publication and published under the title "The Astronomical Ephemeris".

The Office is assisting other departments of the Observatory, particularly the Meridian Department, with the calculations involved in the reduction and discussion of observations. A small electronic computing machine (the Hollerith 1201) is being installed to expand the scope for this work, for the routine calculations of the Office, and for a limited range of theoretical investigations.

The precise motion of the Moon is of foremost importance in relation to the rotation of the Earth and to the determination of Ephemeris Time. The main task of the Office is the calculation of the lunar ephemeris; and it conducts a world-wide programme of occultation prediction, with the collection, reduction and discussion of all observed lunar occultations, as a small part of this task.

Work on the Newton telescope is now to be resumed (see *Nature*, February 28, p. 579).

THE AMERICAN MINIATURE NUCLEAR GENERATOR, *SNAP III*

By W. S. EASTWOOD, L. B. MULLETT and J. L. PUTMAN

Atomic Energy Research Establishment, Harwell, Didcot, Berks

SNAP III, standing for System for Nuclear Auxiliary Power, is a miniature device capable of powering the telemetering apparatus in a space rocket. Its source of power comes from the decay energy generated by a source of radioactive polonium-210. The energy is converted directly to electric current by attaching to the polonium capsule, which heats itself to more than 700° F., a series of twenty radial thermocouple elements in the form of wheel spokes. The generator weighs 5 lb. and is $4\frac{3}{4}$ in. in diameter × $5\frac{1}{2}$ in. high. When originally charged, it held a content of 3,000 curies of polonium-210. At the demonstration at the White House some four months later, an output of 5 watts electrical power was delivered with an efficiency of 8–10 per cent.

The Martin Company of Baltimore built the device for the U.S. Atomic Energy Commission with the Minnesota Mining and Manufacturing Co., which owns patents on the thermocouples, as subcontractors. The contract was for 15,000 dollars, but the polonium source was quoted by the *New York Times* as costing 30 million dollars. Other American reports have given the basic cost of polonium as a hundred times less than this figure.

The polonium-210 is in many ways a convenient isotope to use, since it generates 5·3-MeV. alpha-particles accompanied by a low proportion of gamma-rays. The energy per disintegration is high and can be confined within the containing capsule, with small external background radiation. The whole apparatus may be handled for short times without receiving excessive radiation.

Polonium has a half-life of only 140 days, so that the useful life of this 30-million dollar battery is about four or five months. Only in a space rocket where results are paramount and weight reduction is essential can one imagine a use for such a device. Furthermore, the efficiency of the device falls off in roughly linear fashion with the difference of temperature between the hot and cold junctions, which will fall, of course, as the radiation source decays.

All alpha-emitting isotopes are a hazard, and polonium-210 is in the highest class of toxicity. In *Snap III* it is contained within two stainless steel shells and an outer one of molybdenum. Should the rocket head return to Earth, the need for three capsules will be apparent, since the maximum recommended human body-burden of radiopolonium is less than one hundred thousand millionth of the contents.

Polonium-210 is made by bombardment of bismuth with neutrons in a reactor, followed by chemical separation:

$$^{83}_{209}\mathrm{Bi} + n \rightarrow {}^{83}_{210}\mathrm{Bi} \rightarrow {}^{84}_{210}\mathrm{Po} + \beta$$

Owing to the alpha-particle hazard, all handling must be carried out in a 'dry box', and this together with the heat generated in the sample makes the compaction of 3,000 curies into a small capsule a fair technical achievement. The sealed containers are essential both for stopping the alpha-particles and to prevent diffusion of the polonium by nuclear recoil accompanying decay.

Various methods are known for conversion of atomic radiation to electricity. Direct use of the charged alpha-particles would establish a voltage in the megavolt range, which is somewhat impracticable. The electrons from a beta-active source can also be used directly to activate silicon, germanium or silicon carbide as a semi-conductor. The practical choice is at present confined to those processes using heat as an intermediary, and the most promising devices are thermionic diodes and semi-conductor thermocouples.

In a 'hard' diode, an efficiency of the order of 10–15 per cent has been obtained with a power density of 1 watt/sq. cm. of electrode by leaving very close spacing (about 0·0005 in.) between cathode and anode to reduce the space-charge effect. It is desirable to have a cathode of low work function and an anode of even lower work function for re-entry of the electrons. In principle, a diode could work with anode and cathode at the same temperature. In practice, for a diode of more reasonable geometry the space charge can be neutralized with positive ions, and much effort is being applied to the problem of introducing desirable ions such as cæsium. Any diode scheme, however, requires a temperature of the order of 1,000° C. or more.

Thermocouple devices have also been developed to similar efficiencies, but operating at lower temperatures. The old-fashioned metallic thermocouple is limited to low efficiency by excessive heat conduction, but semiconductors with poor heat transmission characteristics have revolutionized the field. The best material at present available is bismuth telluride doped with selenium and antimony to give negative and positive thermoelectric coefficients. A large number of these units can very conveniently be connected in series electrically and in parallel for heat flow. The efficiency is 5 per cent per 100 deg. C. temperature difference, but the maximum operating temperature is limited to the region of 250° C., above which the efficiency falls and the material is degraded. It is believed that an extension to 400° C. might be possible with special precautions. Lead telluride in alternate n and p type form is used in *Snap*. It has a lower efficiency for a given difference of temperature, but can be used at higher temperatures. The initial efficiency is quoted as 10 per cent, but after a half-life it falls to 5–6 per cent with an output of 3 watts. The initial power output is not directly quoted, but with 3,000 curies and 10 per cent efficiency it should be in the region of 10 watts. This would be consistent with an output after 140 days of the order of 2·5 watts, a factor of two down in power of source and a further two for reduced efficiency. There is insufficient information to determine why lead telluride was used and not bismuth telluride. It could be that bismuth telluride came a little too late, and the higher efficiency per 100 deg. C. is not a very important factor; or there might be a more cogent reason for the high temperature of the source connected with a difficulty in achieving a low temperature of the base in an artificial satellite.

Several other alpha-emitting isotopes might in theory be substituted for polonium, but it is unlikely that the natural or the trans-uranium elements would be available in sufficient quantities. The American press release suggested using the fission products Ce-^{144}Pr (half-life 285 days) having a total beta-energy of 3·3 MeV. Here the compactness of the gadget must be sacrificed. Sources of high-energy beta-rays of this activity will be accompanied by a considerable bremsstrahlung background of X-rays which would require appreciably heavy shielding.

Apart from a better and cheaper supply, no great developments can be expected from the radioactive side of these generators. The methods of conversion, on the other hand, are the subject of considerable research, and new and improved alloys can be expected to raise the temperature of conversion and the efficiency. The stimulus for this work comes, however, from the more important possibilities of direct conversion of reactor heat or waste heat to electricity.

THE INDIAN INSTITUTE OF SCIENCE, BANGALORE, INDIA

GOLDEN JUBILEE

By DR. S. BHAGAVANTAM

Director

THE Indian Institute of Science, which marked its golden jubilee by a special meeting on February 2, owes its existence to the far-sighted vision of the well-known philanthropist, the late Mr. Jamshetji Nusserwanji Tata. Unfortunately, the founder did not live to see the fruition of his idea, and it was left to his two sons, the late Sir Dorab J. Tata and the late Sir Ratan J. Tata, to carry out their father's wishes, with the active support of the late Lord Curzon, the then Governor-General of India, and Sir K. Sheshadri Iyer, who was at that time Dewan of Mysore. Mr. J. R. D. Tata, who is president of the Court of the Institute, opened the jubilee proceedings; the guests included the President of India, H.R.H. the Duke of Edinburgh and the Governor of Mysore.

The Institute may be deemed to have come into formal existence on May 27, 1909, the date of the vesting order of the Government of India. The first batch of students was, however, admitted only in 1911 with the Departments of General and Applied Chemistry and of Electrical Technology commencing to work. The Department of Organic Chemistry was added soon after. The Department of Biochemistry was opened in 1921 and that of Physics in 1933, when Sir C. V. Raman took charge as director of the Institute.

To the first director, Dr. Morris W. Travers, the distinguished chemist, and his colleagues, the Institute owes its sound foundations. Dr. Travers was succeeded by Sir A. G. Bourne (1915–21), Sir M. O. Forster (1922–33), Sir C. V. Raman (1933–37), Sir J. C. Ghosh (1939–48), who has just died (see p. 645), and Prof. M. S. Thacker (1949–55). I took charge in March 1957.

The Institute functions as an autonomous body in accordance with a scheme formulated by the Government of India under the Charitable Endowments Act. Its authorities include the President of the Republic of India as its *ex-officio* Visitor, a Court, a Council, a Finance Committee, a Board of Management for the endowed properties, a Board of Holding Trustees for the other properties, the Senate, the Faculties and the Director. The Director is the Chief Executive and Academic Officer of the Institute.

The Quinquennial Reviewing Committee, 1955, recommended that in place of the diplomas that it had been so far conferring on its students, the Institute should be enabled to confer degrees on them. On the orders of the Visitor, the Institute is now deemed to be a University under Section 3 of the University Grants Commission Act of 1956 for the purposes of that Act and is conferring the degrees of B.E., M.E., M.Sc., Ph.D. and D.Sc. instead of diplomas.

The accompanying figures (Table 1) give an idea of the Institute's expansion since its beginning.

Being in possession of well-equipped laboratories and as the leading postgraduate institution of the

Table 1

Year	Receipts (rounded to nearest thousand) Rs.	Expenditure (rounded to nearest thousand) Rs.	No. of students	No. of members of staff
1911	20,68,000	15,99,000	24	6
1919	3,24,000	3,41,000	73	7
1939	6,58,000	6,08,000	187	20
1947	32,06,000	36,67,000	221	50
1953	58,65,000	54,14,000	373	123
1958	64,05,000	66,64,000	561	157

country for advanced instruction and research in science and engineering, the Institute took up for investigation during the Second World War a large number of schemes of research sponsored by the Council of Scientific and Industrial Research, the Indian Council of Agricultural Research, the Indian Council of Medical Research and the Governments of Madras and Mysore. During that period, the Institute planned and established a Department of Aeronautical Engineering. When the War was drawing to a close, a further four-year expansion programme was launched with grants sanctioned by the Central Government. Under that programme, the Departments of Metallurgy (1945), Internal Combustion Engineering (1945), and Chemical Technology and Chemical Engineering (1951) were established; and laboratories for research in fermentation technology, food technology and pharmacology were set up. For the training of power engineers, a Department of Power Engineering was established in 1947 with laboratories for electrical, mechanical, civil and hydraulic and high-voltage engineering. A Section of Economics and Industrial Psychology, including industrial relations, and affording facilities for research in these subjects, was also started in the same year.

In 1955, under a scheme for the development of facilities for technical education, additional post-graduate courses in automobile engineering (1956), foundry engineering (1956), soil mechanics and foundation engineering (1957), electronic engineering (1956), ultra-short and microwave engineering (1956), line communication engineering and acoustical engineering were provided. Further facilities for research in technical gas reactions, physical metallurgy, hydraulic machines, internal combustion engineering, electrical measurements and measuring instruments, transmission, distribution and network practice have been added. Recently, a Department of Applied Mathematics and a Section of Industrial Engineering and Administration have been established.

The Library of the Institute is one of the best scientific and technical libraries in India.

The Institute publishes a quarterly entitled *Journal of the Indian Institute of Science*, containing original papers by the research workers of the Institute.

A noteworthy feature of the Indian Institute of Science is the objective itself with which it was founded, namely, for the provision of advanced instruction and the conduct of original investigations in all branches of knowledge that are likely to promote the material and industrial welfare of India. The broader the objective, obviously the more difficult will it be of fulfilment. However, the facts that we started with good foundations and established at a very early stage traditions of research in pure sciences like physics and chemistry, that we added later, and at appropriate times, specialized branches of technology like power engineering, metallurgy and aeronautics, and also that we did not quite neglect mathematics and even the humanities are, in my opinion, the principles that helped us to face our task and make its fulfilment come as near the ideal laid down by the founder as possible.

During the past fifty years, the Institute has grown to be one of the foremost centres of scientific research and advanced instruction in India. A large low-speed open-circuit wind tunnel of 9 ft. × 14 ft. test section was inaugurated during the recent jubilee celebrations. This tunnel is the only one of its kind in India, and will offer increased instructional and research facilities in aeroplane design. A modern a.c. network analyser, again the only one of its kind in India, has been in use for some time now in connexion with studies relating to power systems in the country. We are planning to put up and equip a modern acoustical laboratory to serve the purpose of training, research and testing in all branches of acoustics. There are many other lines of development which are not mentioned here for want of space. The Institute's contribution to the instructional aspect is reflected in the fact that more than three thousand of its alumni are now occupying positions of importance and responsibility all over the country in their fields of specialization. The research work done at the Institute has opened a new vista for generations of Indian scientists and engineers who go through its portals. Many young men and women from different parts of the country now eagerly look forward to joining the band of workers at the Institute.

The Institute is, to a high degree, autonomous in character. In the past, we confined ourselves to research and training, largely at the postgraduate level, and we propose to retain this feature in the years ahead. Thus we are able to direct our technological and scientific resources to carefully chosen specific purposes. We hope that against this background the Institute and those associated with it will have a great part to play in promoting the progress of India.

OBITUARIES

Sir J. C. Ghosh

Sir Jnan Chandra Ghosh died suddenly at the age of sixty-four at his Calcutta residence on January 21. I had been closely associated with him for some fifty years.

Sir J. C. Ghosh was a leader in physical chemistry when he was the professor and head of the Chemistry Department of the University of Dacca, which he joined in 1921, being appointed in London by Sir Philip Hartog, the first vice-chancellor of the University. He served this University loyally for twenty years and with conspicuous success as a teacher and research worker. By his devotion to science and his kindly nature, he attracted many young men and initiated them into scientific research. This seems to have been the best period in his career in the service of science and education.

In 1915 Ghosh published his first paper on the electrolysis of solutions by alternating electric current in the *Journal of the American Chemical Society*. During the First World War, Snethlage (*Z. phys. Chem.*, **90**, 1, 139; 1915) published some papers criticizing the Arrhenius electrolytic dissociation theory. I pointed out the weakness of Snethlage's views (*Medd. Nobel Inst.*, **3**, No. 15; 1916), and later developed my views in a paper to the Faraday Society, and a general discussion on the present position of the theory of ionization was organized in London by the Faraday Society on January 21, 1919. In this general discussion Ghosh's contributions to the basic conception of total ionization of electrolytes were considered and discussed and were favourably received by leading physical chemists of Britain, and papers by him were published in the *Journal of the Chemical Society*, London. However, other physical chemists scrutinized the conceptions and arguments of Ghosh and pointed out that they were not valid. Although Sutherland (*Phil. Mag.*, **3**, 161; 1902; **12**, 1; 1906) and Milner (*ibid.*, **25**, 742; 1913) introduced the conception of complete ionization, Ghosh's papers were mainly responsible for the development of this idea and its applications by Debye and Hückel in their theory of strong electrolytes. Later, Ghosh and his collaborators published some interesting papers on catalytic gaseous reactions and photochemistry, which have been followed up elsewhere.

During the Second World War, Ghosh was appointed director of the Indian Institute of Science, Bangalore, which expanded in various directions during his regime. In this period he was knighted, chiefly for his war services.

When Dr. Shyama Prosad Mukherji was appointed Minister in the Union Government, he took Ghosh to Delhi to assist in the expansion of technology in India. After a short stay in Delhi, he was sent to be the first director of the Indian Technological Institute at Kharagpur, West Bengal. Then he was appointed the first whole-time vice-chancellor of the University of Calcutta; but he had to give up this post after a short time on his appointment as a member of the Planning Commission for Science and Technology in India.

Lady Ghosh, three sons and two daughters survive him.

N. R. Dhar

Prof. W. Riddet

Prof. William Riddet, director of the Dairy Research Institute (N.Z.) at Palmerston North, New Zealand, died on December 30 at the age of sixty-two.

Prof. Riddet was born of farming parents in Ayrshire, Scotland. He graduated B.Sc. and N.D.A., N.D.D. (with honours) at the West of Scotland Agricultural College and the University of Glasgow. In 1921 he joined the staff of the West of Scotland Agricultural College, first as dairy instructor and later as lecturer. In 1925 he migrated to New Zealand to take up the then recently established Logan Campbell chair of agriculture at Auckland University College. In co-operation with Prof. G. S. (now Sir Geoffrey) Peren, then Walter Buchanan professor of agriculture at Victoria University College, Wellington, he organized the establishment, in 1927, of Massey Agricultural College, at Palmerston North, to which both professorships were transferred. At about the same time he played a leading part in the arrangements for the development of the Dairy Research Institute (N.Z.), an organization set up under the ægis of the N.Z. Department of Scientific and Industrial Research to undertake scientific research work as a service to the rapidly expanding dairy products manufacturing industry. Prof. Riddet was appointed the first director of this Institute.

Thus it was in the dual role of dean of dairying (and later vice-principal) of Massey Agricultural College and director of the Dairy Research Institute (N.Z.) that Prof. Riddet made his outstanding contribution to the advancement of dairy science and dairy practice, and thereby to the general welfare and prosperity of his adopted country.

Prof. Riddet had from the outset that very important attribute of a leader in teaching and research, an original and ranging mind. His interests covered a wide field; and wherever his interest lay his mind was active in devising and fostering ideas for investigation and research. Endowed with what seemed to be an inexhaustible reserve of energy, he devoted himself to his duties with an astonishing persistency.

As a teacher he set for his students very exacting standards. The value of his teaching is shown in the calibre of the men who came under his influence—they are to be found occupying positions of high responsibility in New Zealand, in Great Britain, and in many other countries. His spirit lives in the training and inspiration he has passed on to these students.

It lives, too, in the organization which he controlled from its beginnings, the Dairy Research Institute (N.Z.). Under his guidance the Institute has gained an international reputation for its work on a number of aspects of dairying practice. While the publications describing this work do not often carry his name as author or co-author, all those who have worked under him will readily acknowledge their debt to him. With typical generosity he made no claims, and passed on his ideas without reservation. It was for him sufficient recompense that he could see the work being done and the Institute serving well the industry from which it drew its support.

The impact of Riddet's personality on the teaching of agricultural science, and on the dairy farming and dairy products manufacturing industry in New Zealand, will be evident for many years to come.

F. H. McDowall

Mr. F. W. James

On January 27, Mr. Francis Wogan James, librarian to the Imperial College of Science and Technology, London, died after years of illness most bravely and cheerfully borne.

From Haverfordwest he went to the Royal College of Science as a Royal Scholar in 1930, and after taking his degree in 1933 he became a research student in inorganic chemistry. During 1936–38 he was research assistant to the professor of highway engineering in the Department of Civil Engineering of the City and Guilds College—a transfer from one to another of the constituent parts of the Imperial College which made it easy for him, in later years, to take a broad view of the needs of the whole College.

In 1938 'Frank' James asked the Dean of the City and Guilds College for permission to apply for the post of College librarian—an appointment which, academically and financially, was junior to the one he was holding—in order to be in a better position to contribute to science and learning by providing his colleagues and the students of the College with books and periodicals. How right he was the members of the College soon realized: although he never obtained a formal qualification in librarianship, he possessed a fine sense of the essentials of library service and a great love of books, and in the past twenty years the library has expanded in size much faster than the College itself and its value to the readers grew from year to year.

His work at the City and Guilds College was interrupted by war service, during 1941–46, in the Army. His work there was mainly concerned with motor transport and with radar, and his bent for these branches of engineering remained in clear evidence when he returned to his College on demobilization.

Frank James loved books, but he took an even greater interest in his readers. He knew hundreds of students by name and the subjects on which they were working, and—being a scientist himself—knew the importance of acquainting them, as soon as a journal arrived, with papers in their fields of interest. Several new lines of research at the College were stimulated by his understanding of papers on similar subjects appearing in what seemed unlikely journals. In addition, he was, when asked, ready to offer his help in the design of apparatus and showed a fine understanding of the construction and use of chemical and electronic equipment.

He possessed great charm and modesty and no member of the College had a greater fund of kindness. Students from overseas were especially grateful to him, for he could sense the needs of shy and lonely people and give them comfort for which they, in turn, gave him their devotion. Frank James will be sadly missed by countless friends who will long remember the kindness received from him and his charming wife. In 1958 he was appointed to be librarian in charge of all libraries at the Imperial College, and it is the College's good fortune that his spirit is alive in his staff.

P. O. WOLF

Dr. Marcel Ballay

DR. MARCEL BALLAY, president and managing director of the Centre d'Information du Nickel, Paris, died on February 2 after a short illness.

Born in 1896, Marcel Ballay entered early upon a career in metallurgy in the laboratory of the de Dion plant, of which he was afterwards appointed head, in 1925. In 1928 he joined the Centre d'Information du Nickel, first as technical manager, becoming later vice-president and in 1954 succeeding M. Jean Dhavernas as president. In 1955 he was appointed an officer of the Legion of Honour in recognition of his services to industry and to the teaching profession. He was a member of many learned societies in France and Great Britain. Under his direction the services offered to industry by the Centre d'Information du Nickel increased in importance, and it is as the head of that office and as a leading and respected metallurgist that Dr. Ballay will be remembered both in France and Great Britain.

NEWS and VIEWS

Airborne Radar at the Royal Radar Establishment: Dr. T. S. England

DR. T. S. ENGLAND, who has been promoted to deputy chief scientific officer and appointed head of the Airborne Radar Department at the Royal Radar Establishment, Malvern, graduated from the University of Durham with first-class honours in physics in 1937 and remained at Durham to undertake research on the heating effects of ultra-short radio waves in dipole solutions. At the outbreak of the Second World War in 1939, he joined the Air Ministry Research Establishment (later the Telecommunications Research Establishment) and worked primarily on the design of radar transmitters, initially at metric and later at centimetre wave-lengths, becoming head of the Transmitter Design Group in 1944. He was given leave of absence from Malvern during 1948–50 to take up a research fellowship in medical physics at the University of Durham, when he applied his extensive knowledge of electronics to studies of the effects of microwave radiations on living tissues and of microwave resonance phenomena in paramagnetic solids and liquids. He was awarded a Ph.D. for his thesis on these researches. On return to the Telecommunications Research Establishment, Dr. England was for a time responsible for research techniques in the millimetre band before being appointed a superintendent of the Radar Ballistics Division at the Royal Radar Establishment in 1956.

Defence Research Policy Staff: Mr. R. V. Whelpton

MR. R. V. WHELPTON, who has been promoted to deputy chief scientific officer and appointed Ministry of Supply representative on the Defence Research Policy Staff at the Ministry of Defence, took his M.Sc. at the University of Sheffield in 1938. After graduating in physics, he spent the next eight years with the research department of the Metropolitan-Vickers Electrical Company, where he worked on high-voltage research and on the development of the high-speed cathode-ray oscillograph. He was also engaged on investigations of transient phenomena in switchgear and the development of the electron microscope. In 1936 he joined Sir Robert Watson-Watt's original team on research and development of ground radar at Orfordness and Bawdsey. This work in 1940 was transferred to the Royal Aircraft Establishment at Farnborough, where Mr. Whelpton was also concerned with other aspects of radio research and development. In 1949 he continued on the same work with the Directorate of Electronics Research and Development at headquarters of the Ministry of Supply. In 1955 he was appointed scientific adviser on air defence to Supreme Headquarters Allied Powers in Europe (SHAPE) and was a member of the study group which led to the formation of the SHAPE Air Defence Technical Centre (SADTC) in The Hague. While at The Hague, as senior British representative, Mr. Whelpton pioneered efforts to enable SADTC to promote integrated air defence for Nato. Mr. Whelpton is a Fellow of the Institute of Physics and he has published a number of papers, two of which have been awarded premiums by the Institution of Electrical Engineers.

Ministry of Supply: Mr. J. H. Phillips

MR. J. H. PHILLIPS has been promoted to deputy chief scientific officer and appointed to the headquarters post of director of Guided Weapons (Techniques). In this post he will be responsible for directing research and development on guidance and control techniques, advanced engineering techniques specially applicable to guided weapons and on propulsion. His career as a scientist has been almost entirely in the Government service. After taking an honours degree in physics at the University of London in 1937, Mr. Phillips worked throughout the Second World War on radio and radar problems, first at Bawdsey Manor and later at the Telecommunications Research Establishments at Swanage and Malvern. This was followed by a two-year term as guided weapons liaison officer in the British Supply Mission (now British Joint Services Mission) in Washington. Moving then to the Royal Aircraft Establishment, Farnborough, he worked for four years in the Guided Weapons Department at the most formative period of this new activity. Thence he was transferred to the headquarters staff of the Ministry of Supply on similar work, and for the past two years has been serving as head of the guided weapons group in the British Joint Services Mission, Washington.

Communication Principles at the Bell Telephone Laboratories: Prof. J. W. Tukey

PROF. J. W. TUKEY, professor of mathematics at Princeton University and a member of the mathematical research department of the Bell Telephone Laboratories, has been appointed assistant director of research in communications principles at those Laboratories. Prof. Tukey will continue to occupy the chair of mathematics at Princeton, a post he has held since 1950.

A native of New Bedford, Massachusetts, Prof. Tukey graduated in chemistry from Brown University in 1936 and was awarded the degree of Ph.D. by Princeton University in 1939. He joined the technical staff of the Bell Laboratories in 1945. His work has covered development of new statistical techniques; broad analysis and synthesis problems related to complex weapons systems; and other problems with mathematical or statistical aspects. He was a Jacobus Fellow at Princeton in 1938–39, a Fellow of the John Simon Guggenheim Memorial Foundation in 1949–50, and a Fellow at the Center for Advanced Study in the Behavioral Sciences in 1957–58. Prof. Tukey is a member of the Division of Mathematics of the National Research Council and serves on several of the Council's committees, including the Committee on Atmospheric Sciences and the Committee on Behavioral Sciences. He has also served on a number of advisory committees to the United States Government, frequently in connexion with military problems.

Zoology at University College, Canberra: Prof. J. D. Smyth

THE news of Prof. J. D. Smyth's appointment to the chair of zoology in the newly established Science Faculty in University College, Canberra, has been received with mixed feeling by Irish zoologists. A Dublin man and a graduate of the University of Dublin, he has spent the greater part of his academic life in his Alma Mater. In 1948, he returned to Dublin when he was made a Fellow of Trinity College and lecturer in zoology. In 1954, he became a professor of experimental zoology. Prior to his return to Dublin, Dr. Smyth held appointments in the Universities of Leicester and Leeds. Prof. Smyth is known to physiologists and parasitologists alike through his research on the physiology of tapeworms. This work chiefly concerns the culturing of the Pseudophyllidae *in vitro*. His technique permits the aseptic removal of the plerocercoid larvæ from the body cavity of fish and their cultivation in various media. By raising the temperature to 40° C., he induced the plerocercoid to mature and reproduce. One interesting result of his work indicates that development, as far as oviposition, depends on some bacterial by-product in the medium. Work on *Ligula intestinalis* has yielded fertile eggs which hatched into normal coracidia, proving a much-debated point that the tapeworm is self-fertile. Using a similar technique, Smyth also succeeded in showing that *Schistocephalis solidus* produced *in vitro* eggs capable of up to 85 per cent embryonation. Dublin has just conferred the degree of Sc.D. on Prof. Smyth—a fitting distinction and well earned. To him, his wife (Mildred Moore, also a graduate in zoology of the University of Dublin) and his two sons, his friends wish many happy years in the country of their adoption.

H. J. Hamburger (1859–1924)

THE distinguished Dutch physiological chemist, Hartog Jakob Hamburger, was born at Alkmaar a century ago on March 9, 1859. He studied chemistry at the University of Utrecht and, after obtaining his doctorate in science, served for seven years as assistant in physiological chemistry to Franz Cornelis Donders. Having graduated M.D., he became lecturer in physiology and pathology at the Utrecht Veterinary School in 1888, and in 1901 he was elected to the chair of physiology at Groningen, where ten years later he was responsible for creating a magnificent new institute. He was president of the International Physiological Congress held at Groningen in September 1913 on the occasion of the twenty-fifth anniversary of its foundation.

A skilled designer of ingenious and deceptively simple experiments and a tolerant and kindly man, Hamburger is remembered eponymously for his 'phenomenon' (the chloride shift); his 'interchange', also called 'secondary buffering'; and his 'law', which states that, when blood is rendered acid, albumins and phosphates pass from the red blood corpuscles to the serum and the chlorides pass from the serum to the cells, and that the reverse occurs when the blood is rendered alkaline. As early as 1867 Nathan Zuntz had suggested that carbon dioxide is carried in the plasma by virtue of some substance present in the red blood corpuscles. It was Hamburger who furnished the final proof of this theory. Hamburger's best-known book is entitled "Osmotischer Druck und Ionenlehre in den medizinischen Wissenschaften" (three vols., Wiesbaden, 1902–4). He also contributed to our knowledge of calcium ions in phagocytosis and of næmolysis. A member of the Royal Academy of Amsterdam and recipient of many honorary degrees, Hamburger died at Groningen on January 4, 1924, aged sixty-five.

Peaceful Uses of Outer Space

Mr. R. Allan, Under-Secretary of State for Foreign Affairs, stated in a written answer in the House of Commons on February 24 that last December the General Assembly of the United Nations set up an *ad hoc* Committee to study the question of international co-operation in the peaceful uses of outer space under United Nations auspices. The Committee, which is composed of eighteen member States, including the United Kingdom, the United States of America and the Soviet Union, is to consider the co-ordination of national research programmes. So far, the Soviet, Polish and Czechoslovak delegates have refused to participate in the work of this Committee, but Mr. Allan hoped that they will reconsider their decision.

Research on Road Accidents

In a written reply to a question in the House of Commons on February 25 as to the steps being taken to increase research on the prevention of road accidents, Mr. H. Nicholls, Parliamentary Secretary to the Ministry of Works, representing the Lord President of the Council, said that extensive researches with this objective generally were being carried out by the Road Research Laboratory. This covered such problems as the control of vehicles during emergency braking, improvements in tyres and road surfaces to give better adhesion on wet roads, improvements in vehicle and street lighting, and in helmets for motor-cyclists. Safety aspects of motor-vehicle design to minimize injuries in road accidents were being investigated in the Slough area in co-operation with the police and the Medical Research Council. The staff available for this detailed study had recently been increased, and facilities for simulating accidents and testing individual components were being built up. Full co-operation existed, and the Laboratory studied research results obtained in the United States and elsewhere with a view of their application here. In 15 per cent of accidents studied in 1955–58 a mechanical defect in the vehicles had played an important part and about half the defects were in the brakes.

Chapelcross Nuclear Power Station

At the United Kingdom Atomic Energy Authority's nuclear power station at Chapelcross, near Annan, Dumfriesshire, the first of the four reactors, which became critical last November, has now been taken in service for the generation of electricity. The Chapelcross station, which will have a generating capacity of 184,000 kW. and will, when all four reactors are completed, feed about 140,000 kW. to the national grid, has been built by the United Kingdom Atomic Energy Authority as a dual-purpose station to provide plutonium and electricity. Another nuclear power station is being built by the South of Scotland Electricity Board at Hunterston in Ayrshire for the provision of electricity and will supply 320,000 kW. of power to the grid. The construction of Chapelcross is under the control of Messrs. Merz and McLellan, acting as agents for the Atomic Energy Authority's Industrial Group; this is the first occasion on which a private firm has been employed in this way in Britain on a major project. The official opening of the Chapelcross Station, by Sir John Crabbe, Lord Lieutenant of Dumfriesshire, will be on May 2, when it will be open to the public.

New Oceanographical Ship for Woods Hole

The sea-going fleet of the Woods Hole Oceanographic Institution, Massachusetts, was recently increased to five ships by the addition of the 92-ft. auxiliary ketch *Aries*, to do scientific work around Bermuda under Dr. John Swallow. Purchase of the ship was made possible with funds made available for the purpose by Mr. Richard J. Reynolds, of Sapelo Island, Georgia. *Aries* will be used mostly to study sub-surface ocean currents with the aid of Dr. Swallow's neutrally buoyant floats, which were used last year in the discovery of a counter-current under the Gulf Stream and in studying the outflow of Mediterranean water through the Straits of Gibraltar in the co-operative effort of the British National Institute of Oceanography and the Woods Hole Oceanographic Institution during the recent International Geophysical Year.

Built in 1953 of teakwood over steel frames, at the Camper and Nicholson Yard in Gosport, *Aries* was designed for world-wide cruising and is well appointed. Aft there is generous room for nine, and her forecastle has room for six. The ship is 70 ft. long on the water line, and has a beam of 19½ ft. and a draught of 12 ft. *Aries* is equipped with a 100-h.p. AEC Diesel engine capable of driving the ship at 8 knots and has a fuel capacity for 2,000 miles. Built to Lloyd's highest specifications, the vessel has copper sheathing on the bottom. The ship will remain under the command of her captain, John W. Gates; the Woods Hole Oceanographic Institution will operate her with a crew of eight. The fleet of the Woods Hole Oceanographic Institution also includes the 213-ft. *Chain*, the 142-ft. *Atlantis*, the 125-ft. *Crawford* and the 110-ft. *Bear*. Two small vessels, *Asterias* and *Risk*, are used for inshore work.

College Biology Courses on Television

The Fund for Advancement of Education established by the Ford Foundation has awarded Station *KETC-TV* and Saint Louis University a grant of 58,300 dollars to cover the academic costs for the production of a film series entitled "Principles of Genetics". The series of forty-five films, to be financed by the McGraw-Hill Co. of New York, are scheduled to be shown over *KETC-TV* network initially in the spring semester of 1960 and will serve as the basis for a regular college credit course in genetics. Simultaneous with the initial showing in Saint Louis, the films will be available to all colleges, universities, hospitals and industries throughout the world. Prof. John D. Dwyer, director of the Department of Biology, and Dr. Irwin H. Herskowitz, associate professor of biology in Saint Louis University, will serve as special consultants in the organization of scientific data for the series of films. The subject-matter will be recorded on film by leading specialists in the field of heredity, and is the first television series in biology, given by a number of leading scientists, of the Educational Television Station's plan for a College of the Air.

Brachiosaurus Exhibit at the Smithsonian Institution

The Smithsonian Institution has recently placed on exhibit in the Dinosaur Hall of its Natural History Building at Washington one of the largest dinosaur limb bones ever known. It is the humerus (upper arm bone) of the sauropod dinosaur, *Brachiosaurus altithorax*, and it was discovered by D. E. Jones of Delta, Colo., who presented it to the Smithsonian. Geologically speaking, it is from the Morrison formation, of late Jurassic age (about 130 million years ago), in Montrose County, Colo. The bone is 6 ft. 10 in. long. *Brachiosaurus* was a giant among dinosaurs, much larger than the familiar *Brontosaurus*; it may have weighed as much as 55 tons. It is distinguished from other dinosaurs by the fact that its front legs were somewhat longer than its hind legs. This feature, the great length of the neck, and the projecting nostrils on top of the head seem to have been adaptations to its presumed habits. *Brachiosaurus* was a plant-eater that walked along the bottoms of lakes, lifting its head above the surface of the water to breathe. *Brachiosaurus* is known from North America, Africa and Europe.

Ethnographic Films

THE Ethnographic Film Committee of Great Britain and Ireland presented three films at the National Film Theatre on March 1. Prof. C. von Fürer-Haimendorf, who has recently returned from nine months field work in a Sherpa village on the Nepal–Tibet border, presented a colour film showing the Sherpas at work in their fields and with their yaks. It also showed a Buddhist festival in a monastery headed by a reincarnate lama. David Attenborough went to New Guinea as a zoologist in search of birds of paradise. He and his cameraman, Charles Lagus, filmed courtship and wedding ceremonies of some of the highland tribes. The film also showed the native method of manufacturing salt and of making the stone axes which are now largely used for ceremonial and prestige purposes. The Iban dyaks of Sarawak were formerly renowned as head-hunters, and head-hunting ritual still plays an important part in their lives. Hugh Gibb, with the co-operation of Tom Harrisson, curator of the Sarawak Museum, made a colour film showing their slash-and-burn method of cultivating rice, tattooing, weaving, and many aspects of domestic life in the long houses in which entire communities live, each family in its separate apartment.

The Ethnographic Film Committee of Great Britain and Ireland is a committee of the Royal Anthropological Institute. It was established as the national committee in 1958 by the Joint Committee for Anthropological Research and Teaching, to co-operate with the national ethnographic film committees of other countries. In addition to sponsoring film programmes for teaching and public presentation, the Committee is preparing a catalogue of ethnographic films available in the United Kingdom.

Department of Scientific and Industrial Research Grants for Students

UNDER its second five-year plan, the Department of Scientific and Industrial Research proposes to increase substantially the number of its postgraduate studentships and fellowships in science and technology. By 1963–64 expenditure on this scheme is expected to exceed £1·5 million and the postgraduate students supported to number 3,800 in place of the present nearly 1,900. Grants for special research projects at universities and colleges under the Department's scheme, including provision for research in the human sciences in relation to industrial needs, are expected to increase three- to four-fold, to about £1·75 million in 1963–64. The latest issue of "Notes on D.S.I.R. Grants for Graduate Students and Research Workers" (pp. 28. London: H.M. Stationery Office, 1959. 1*s*. 9*d*. net) gives full details of the regulations governing such awards, with an appendix on awards tenable abroad. The rates for the latter, while varying from country to country, will be equivalent to those received by a student or a Fellow in Britain, and in addition, second-class rail fare and travel subsistence will be paid. Research fellowships vary between £700 and £850 a year and are normally held for two years. Under the studentship scheme, approved fees are paid to the appropriate authority and the maintenance grant paid to the student varies from £420 a year to students living in college, hostel or lodgings at Oxford and Cambridge, £400 at London and £340 elsewhere, to £285 to students living with parents in London and £270 to students living with parents elsewhere.

International Association for the Exchange of Students

THE report for the year ended September 1958 of the International Association for the Exchange of Students for Technical Experience is accompanied by a survey of the first ten years of the Association in Great Britain during 1948–57. In the summer vacation of 1958, 776 students went abroad and 829 students were received; forty-two universities and colleges are now affiliated and twenty-four countries participate, Of the 4,968 students sent abroad from Great Britain under the Association in 1948–57, nearly a third (1,504) were from the Imperial College of Science and Technology; 272 were from the University of Durham, 263 from Birmingham, 220 from Bristol, 238 from Manchester, 228 from Cambridge, 186 from Glasgow, 180 from University College, London, and 173 from the University of Leeds. In 1958 it became necessary to restrict the nomination of students to those completing the penultimate year on an undergraduate course who had already had some previous industrial experience in Britain. Stress is laid on the contribution by British industry, and an evaluation of the exchange based on information from reports on 4,269 students indicates the undoubted success of the scheme. With scarcely any exception, the students proved genuinely anxious to work hard and gain the maximum benefit, but the vital necessity of great care in selecting students for the exchange is stressed.

Grants for Study Overseas

THE British Council handbook entitled "Scholarships Abroad, 1959–60" (pp. iii + 27. London: British Council, 1959), to which the director-general, Sir Paul Sinker, contributes a foreword, lists by country awards offered by foreign governments and universities to enable British students to continue their studies abroad. Mostly they are offered annually, and the handbook includes particulars of conditions, value, duration and fares as well as of method of application and the closing date for receipt of applications.

Toxicology and Applied Pharmacology

AFTER the recent appearance of a new British pharmacological journal, *Biochemical Pharmacology*, it comes as somewhat of a shock that a new toxicological journal has been published in the United States. For each individual scientist it becomes increasingly difficult to keep up with the literature, and the immediate reaction to any new item on the list of journals is one of resentment. However, it is true that, as the editors of *Toxicology and Applied Pharmacology* point out, an increasing number of toxicological investigations are carried out in industry, government departments and universities, and that it would help the workers in toxicology to have the investigations collected in a single journal rather than scattered in many periodicals. It may, in fact, relieve pressure on the space available in the existing pharmacological journals if some of the toxicological material need no longer be published there. The new journal will only publish papers written in English, and the first issue consists of papers by authors from the North American continent. The editorial board, however, includes non-American members, so that contributions by authors from other continents will obviously be welcome. The first issue of *Toxicology and Applied Pharmacology* (1, No. 1; January 1959. Pp. iv + 1–118. Published bi-monthly. Annual subscription, 13 dollars or 93*s*. New York and London: Academic Press, Inc., 1959) contains eleven papers, mostly on toxicity tests in animals. It is well produced, but it may be regretted by some readers that the summaries of the papers are in small print, since they are the most widely read part of a journal.

Report of the Imperial College of Science and Technology, London, for 1958

The fifty-first annual report of the Governing Body of the Imperial College of Science and Technology, London, for the year ended July 31, 1958, records a further increase in the number of students. Full-time undergraduate students numbered 1,589 and postgraduate students 848, increases of 74 and 148, respectively, on the previous year, while part-time students (nearly all postgraduates) increased from 324 to 674. The teaching staff increased from 353 to 380, bringing the total of professors and readers to 36 and 62, respectively. The growing importance of nuclear technology was marked by the appointment of a reader in nuclear technology in the Department of Chemical Engineering, and the work done in the study of automatic control systems in the Department of Electrical Engineering is being extended to take account of the needs of other departments. At the end of the session the College's proposals for a new residential block to house nearly 400 students and provide refectory and common-room space for larger numbers was approved. Besides the statement of accounts, departmental notes and lists of publications, appendixes to the report include lists of special lectures, details of staff changes and Sir Alexander Fleck's address on Commemoration Day in October 1957.

Digitizers and other Equipment for Data Processing

Data processing schemes are generally required to handle information which is originally in analogue form, that is to say, the signal takes the form of a continuous variable. For transmitting this information it is convenient to quantize it into discrete steps and then to transmit it in digital form. A descriptive catalogue published by Hilger and Watts, Ltd., London, and entitled "Digitizers and other Equipment for Data Processing", describes the principles of operation, and gives full technical information concerning a number of analogue – digital converters or digitizers, mainly of the type in which an input shaft drives a coded disk. Both mechanical and optical read-off systems are available. Details are also given of various ancillary equipment, including numerical displays, amplifiers and a typewriter for printing values of measured variables.

Scientific Careers in the Ministry of Supply

Under the title "An Invitation to Science Graduates", the Ministry of Supply and Central Office of Information have issued a booklet describing scientific careers open in the Ministry of Supply, copies of which are being sent to honours graduates in science as they qualify in British universities over the next two or three years. Besides indicating the nature of the careers, conditions of service, opportunities for promotion, the booklet gives particulars of how to apply.

Biological Effects of Space Flight
